ORDELLO, a 13th-century Italian troubadour, born at Goito (c. 1200), who is praised by Dante in the De vulgari eloquentia, and in the Purgatorio is made the type of patriotic pride. He is the hero of a well-known poem by Robert Browning. The real Sordello was the most famous of the Italian troubadours. About 1220 he appeared at Florence in a tavern brawl; and in 1226, while at the court of Richard of Bonifazio at Verona, he abducted his master's wife, Cunizza, at the instigation of her brother, Ezzelino da Romano. The scandal resulted in his flight (1229) to Provence,

where he seems to have been for some time. He entered the service of Charles of Anjou, and probably accompanied him (1265) on his Naples expedition; in 1266 he was a prisoner in Naples. The last documentary mention of him is in 1269, and he is supposed to have died in Provence. His didactic poem, L'Ensenhamen d'onor, and his love songs and satirical pieces have little in common with Dante's presentation, but the invective against negligent princes which Dante puts into his mouth in the 7th canto of the Purgatorio is more adequately paralleled in his Serventese (1237) on the death of his patron Blacatz, where he invites all Christian princes to feed on the heart of the hero.

SORDINO, SORDONI, SORDUN, musical terms somewhat promiscuously applied (1) to contrivances for damping or muting wind, string and percussion instruments (Sordini); (2) to a family of obsolete wind instruments blown family of obsolete wind instruments blown by courtest of Messes. Hooper by means of a double reed (Sordoni or AND JACKSON Sordun); (3) to a stringed instrument. SORDING, AN OBSOLETE To these must also be added the Surdel- STRING INSTRUMENT

ling or Sordelling, a kind of musette invented (see BAG-PIPE) in Naples in the 17th century.

SOREL, AGNES (c. 1422-1450), mistress of King Charles VII of France, was born of a family of the lesser nobility at Fromenteau in Touraine. She was attached to the service of Isabel of Lorraine, queen of Sicily, wife of René of Anjou, the brother-in-law of Charles VII. After 1444 until her death in 1450 she was the acknowledged mistress of the king, the first woman to hold that semiofficial position which was to be of such great importance in the subsequent history of the old regime. Her ascendancy dated from the festivals at Nancy in 1444, the first brilliant court of Charles VII. Her sudden death from dysentery, shortly after the birth of her fourth child in 1450, was

attributed, apparently without foundation, to poison.

SOREL, ALBERT (1842-1906), French historian, was born at Honfleur on Aug. 13, 1842. He was of a characteristically Norman type, and remained all his life a lover of his native province. He studied law in Paris, and entered the foreign office (1866). In 1870 he was chosen as secretary by M. de Chaudordy, who had been sent to Tours as a delegate in charge of the diplomatic side of the problem of national defense; in these affairs he proved himself a most valuable collaborator. After the war of 1870-71, when Boutmy founded the École libre des sciences politiques, Sorel was appointed to teach diplomatic history (1872), a post in which he achieved great success

Some of Sorel's courses have formed books: Le Traité de Paris du 20 novembre 1815 (1873); Histoire diplomatique de la guerre franco-allemande (1875); also the Précis du droit des gens which he published (1877) in collaboration with his colleague Théodore Funck-Brentano. In 1875 Sorel left the foreign office and became general secretary of the Présidence du sénat.

His duties left him sufficient leisure for the great work of his life, L'Europe et la révolution française (8 vols., 1885-1604). His object was to do over again the work already done by Stbel, but from a less restricted point of view and with a clearer and more calm understanding of the chessboard of Europe. He spent almost 30 years in the preparation of this history; the analysis of the documents, mostly unpublished, on French diplomacy during the first years of the Revolution, which he published in the Revue historique (vol. v-vii, xi-xiii), shows with what scrupulous care he read the innumerable despatches which passed under his notice.

Sorel was elected a member of the Académie française (1894). He died in Paris on June 29, 1906.

Sorel's other works include: La Question d'Orient au XVIIIe stècle,
Sorel's other works include: La Question d'Orient au XVIIIe stècle,
e les origines de la triple alliance (1878); Montesquieu (1887) and
Mme. de Stalet (1801) in the Grands écrivans series; Bonaparte et
Hoche en 1797 (1896) and Recueil des instructions données aux
ambassadeurs, vol. i only (1884). Most of his essays and articles
contributed to various reviews and to the Temps have been collected.

SOREL, CHARLES, SIEUR DE SOUVIGNY (1597-1674). French novelist, was born in Paris about 1597. In 1635 he was historiographer of France. He wrote Histoire comique de Francion (1622), Le Berger extravagant (1627) and Polyandre (1648). He died on March 8, 1674.

SOREL, a city of Quebec, Can., at the confluence of the Richelieu and St. Lawrence rivers, 45 mi. N.E. of Montreal; on the Canadian National railways. Pop. (1951) 14,961. It occupies the site of a fort built in 1665 by A. de Tracy to guard the route by way of the Richelieu to Lake Champlain and the Hudson. There are major shipbuilding and armament works.

SORGHUM, a cereal, forage and syrup crop plant grown largely in warm countries and known botanically as S. vulgare (Andropogon Sorghum or Holcus Sorghum), Sorghum probably

originated in Africa. It is one of the most important tropical grains. The types grown for grain (grain sorghum) are called by various names, including durra, Egyptian corn, great millet or Indian millet. In India it is known as jawari (Hindustani), jowari (Bengali), cholum (Tamil) and jonna (Telugu), and in the West Indies as petit mil or Guinez-corn. In China and Manchuria it is called kaoliang. It is a strong grass, growing to a height of from 2 to 8 or even 16 ft. The stalks and leaves are coated with a white waxy bloom. The pith in the stalks of different varieties may be juicy or rather dry. The juice may be sweet or non-sweet. The leaves are sheathing, solitary and about 2 in. broad and 21 ft. in length; the panicles are loose, contracted or dense. Self-pollination of the flowers is common but considerable cross-pollination occurs. The grains may be either free or retained in the hulls after thresh- MILLET OR GUINEA CORN (SORing. Many varieties are awned. The seeds are ellipsoid, rounded or flattened and of varied sizes somewhat smaller than wheat

GHUM VULGARE)

(A) Shoot, (B) Flowering stem (inflorescence), (C) Pistil, (D) Fruit, (E) Single flower, (C & E) Enlarged grains. The seeds may be white, yellow, red or brown. The hulls are mostly straw-coloured, red, brown or black.

Sorghum is the leading cereal grain in Africa and is important also in India, north China, Manchuria and the United States. It is grown to some extent in Russia, Persia, Arabia, Argentina, Australia and southern Europe, as well as in other regions. It is best adapted to warm conditions and is very resistant to drought and heat. Hundreds of varieties are grown in various parts of the world. The grain is similar in composition to that of maize except in being higher in protein and lower in fat. For food it usually is ground it to a meal and made into porridge, bread or cakes. Natives of south Africa refer to the product as "mealies." Whole grains sometimes are popped or puffed. The grain also is used in making alcoholic beverages. The sweet sorghums (sorgos) are grown chiefly in the United States and south Africa for forage or for syrup manufacture. The sweet stalks are chewed by natives in various countries. The broomcorn plant, belonging also to the species S. vulgare, is similar to other sorghums in adaptation and many r int characteristics.

For a full account of the cultivation and use of the species in India see Sir G. Watt's Dictionary of the Economic Products of India (1893).

See also W. W. Robbins, Botany of Crop Plants (1931). (J. H. Mn.)

SORIA, a province of Spain, formed in 1833 out of Old Castile. Pop. (1950 census) 161,182; area, 3,977 sq.mi. Soria is a bleak region, bounded on three sides by mountains. A range of sierras culminating in the peaks of Urbion (7,392 ft.) and Cebollera (7,024 ft.) on the north and the great Sierra del Moncavo (7,595 ft.) on the east separate the valley of the Duero from the Ebro. Almost the whole of the province belongs to the region watered by the Duero and its affluents. There are forests of pine, oak and beech and large tracts of pasture land. The climate is cold and dry, and the scenery austere.

SORIA, the capital of the Spanish province of Soria; on the river Duero (Douro). Pop. (1950) 16,878. The churches of Santa Domingo and San Nicolas, the collegiate church of San Pedro, the cloisters of the convent of San Juan, and several other ecclesiastical buildings are fine specimens of Romanesque work of the 12th and 13th centuries. Near the Duero are the ruins of the old citadel, and the 13th century walls remain.

SORITES, in logic, means a series of connected syllogisms, in which the conclusion of one syllogism is used as a premise in another. See Logic and the bibliography given there.

SORMOVO, a town of the Russian S.F.S.R., in the Nizhegorod region, on the Volga. It was a village of about 6,000 inhabitants in 1897, but grew after the provision of electric power to a population of 40,071. It manufactures machinery and refines crude Baku naphtha brought up the Volga river.

SOROCA, a town of Bessarabia, on the right bank of the Dniester, 81 mi. N.N.W. of Kishinev. Pop. (1930) 14,661, including many Jews. Corn, wool, fruit, wine and cattle are exported. Soroca was the old Genoese colony of Olchiona and still has the ruins of a 13th century Genoese castle. The Moldavians erected a fortress in the 15th century. Soroca changed hands many times between Poland, Russia and Turkey; in 1940 Rumania ceded it to the U.S.S.R. but regained it the next year.

SOROLLA Y BASTIDA, JOAQUIN (1863-1923), Spanish painter, was born at Valencia on Feb. 27, and studied at the academy there, in Italy and in Paris, where he especially interested himself in the works of J. Bastien-Lepage and A. von Menzel (qq.v.); he was also influenced by the north European realists, particularly A. Zorn (q.v.). His early paintings were of history and social realism (one of the latter kind, "Oltra Margarita," 1892, now at St. Louis, being his earliest success), but he later became well known for brightly lit scenes with Valencian peasants and fisherfolk and children playing in the surf, his style after about 1903-04 becoming impressionistic and summary, with heavily impasted pigments. Between 1910 and 1920 he painted portraits of Spanish writers and a "Panorama of the Forty-nine Provinces of Spain" for the Hispanic Society of America. He died in Madrid on Aug. 10, 1923.

BIBLIOGRAPHY.—A. de Beruete y Moret et al., Eight Essays on Joaquin Sorolla y Bastida, 2 vol. (New York, 1999); R. Doménech, Sorolla y (Madrid, 1919); A. de Beruete y Moret, Sorolla y Bastida (Madrid, 1920); Sorolla in the Collection of the Hispanic Society of America (New York, 1926).

SORORATE. This term was introduced by Sir James Frazer to designate all marriages with a wife's sister, whether in the lifetime of the first wife or after her death. In his view, generally accepted today, it is complementary to the custom of the levirate. (Folklore of the Old Testament, vol. ii, p. 317.) The concept already appears in E. B. Tylor's "On a Method of Investigating the Development of Institutions" (Journal of the Anthropological Institute of Great Britain and Ireland, vol. xviii, pp. 245-269, 1889), where levirate and sororate correctly figure as correlates of the postulate that matrimony is a bond between families rather than individuals. A. R. Radcliffe-Brown subsumes both institutions under the principle of the social equivalence of brothers and sisters, respectively. These relationship terms are to be understood in a classificatory sense, i.e., a more remote relative of the same sex may serve as secondary mate instead of a blood sibling. Though related in principle, levirate and sororate

are not invariably associated, but they usually are, and appear to be the commonest of preferential secondary marriages. Either may be permissive rather than obligatory. The Maricopa (Arizona) insist on a widow's marrying a husband's relative, whereas the replacement of a deceased wife by a kinswoman of hers is customary, but not compulsory.

Though successive and simultaneous marriage of two or more sisters falls under the same principle, some tribes, e.g., the Kazak, favour one, while tabooing the other practice. Hence it has become necessary to distinguish between sororal polygyny and sororate. The typical rule for the former is that the husband of the eldest girl in a family marries her juniors as they come of age; L. H. Morgan found this usage in at least 40 North American tribes; and even recently Navaho men often were simultaneously married to two sisters, occasionally to three. Australian aborigines recognized the same pre-emptive claim, but in many tribes the husband contented himself with the two oldest girls, conveying his claims on their younger sisters to his junior brother. With remarkable unanimity aborigines explain sororal polygyny on the ground that sisters are unlikely to quarrel as co-wives. The effect of both the sororate and sororal polygyny is to have children extend the term "mother" to the maternal aunt, but this terminological trait is more probably directly correlated with unilinear descent (George P. Murdock).

SORORITIES, national Greek letter organizations of women in colleges and universities in the United States and Canada. Sororities are self-perpetuating, each having a characteristic badge and symbolic insignia. In the 1950s there were more than 1,700 college chapters in about 250 colleges in the United States and Canada; about 3,900 alumnae groups and a total membership of about 800,000. The governments of all are similar—a council of five to nine members to carry out legislation enacted at national or district conventions. Many sororities have accumulated endowment funds, offer scholarships, maintain loan funds for members and support national philanthropic projects. Practically all sororities maintain a central office, publish quarterly magazines, song books. manuals and bulletins.

The National Panhellenic conference was formed in 1902 as an organization of national sororities. (R. L. F.; M. C. H.)

SORREL (Rumex acetosa) (family Polygonaceae), a hardy perennial, native to Great Britain, Europe and Asia, and found throughout the north temperate zone. The leaves are used in soups, salads and sauces and as a pot herb. Sorrel grows freely in any good garden soil, and is propagated either by seeds or by dividing the roots during the early part of spring. They should be planted in rows 15 to 18 in. apart. The leaves, when fully grown, are gathered singly. The common garden sorrel is much superior to the wild plant called dock in the United States; French sorrel (Rumex scutatus) is a hardy perennial, distributed through Europe but not native in Great Britain.

SORRENTO, a city of Campania, Italy (ancient Surrentum). Pop. (1951) 10,837. Sorrento stands on cliffs about 160 ft. high, between the Bay of Naples and the Bay of Salerno. It is a summer and winter resort, its northerly aspect rendering it comparatively cool. At Sorrento Bernardo Tasso wrote his Amadigi; Torquato Tasso was born there. The most important temples of the ancient city were those of Athena and of the Sirens, the latter the only one in the Greek world in historic times. The place was famous for its wine, its fish and its red Campanian vases. It was protected by deep gorges, except for a distance of 300 yd. on the southwest, defended by walls, the line of which is followed by those of the modern town. The arrangement of the modern streets also preserves that of the ancient town. On the east the most important ancient ruin is the reservoir of the subterranean aqueducts. which had 27 chambers. There are also remains of villas, including that of Pollius Felix, the friend of Statius.

SORSOGON, a municipality, capital and port of the province of Sorsogon, Luzon, Philippines, on the Gulf of Sorsogon, 279 mi.

de

from Manila. Pop. (1948) 26,004. Abacá (Manila hemp) is the chief product. Bikol is the vernacular. Of the inhabitants aged 6 to 19 inclusive, 35 6% were reported in 1939 as attending school.

SOSIGENES, Greek astronomer, and mathematician, probably of Alexandria, flourished in the 1st century B.C. According to Pliny (Nat. Hist. xviii, 25), he was employed by Julius Caesar in the reform of the Roman calendar (46 B.C.), and wrote three treatises. From another passage of Pliny (ii, 8) it is inferred that Sosigenes maintained the doctrine of the motion of Mercury round the sun, which is referred to by Cicero, and was also held by the Egyptians. He was the tutor of Alexander of Aphrodisias. He wrote Revolving Spheres, from which important extracts are preserved in Simplicius' commentary on Aristotle's De caelo.

SOSITHEUS (c. 280 s.c.), Greek tragic poet, of Alexandria Troas, a member of the Alexandrian "pleiad." He must have resided at some time in Athens, since Diogenes Laërtius tells us (vii, 5, 4) that he attacked the Stoic Cleanthes on the stage and was hissed off by the audience. Suïdas calls him a Syracusan. According to an epigram of Dioscorides in the Greek anthology (Anth. Pal. vii, 707) he restored the satyric drama in its original form. Part of his pastoral play, Daphnis or Lityerses, is extant.

See O. Crusius s.v. Lityerses in Roscher's Lexikon der griechischen und römischen Mythologie. The fragment in Nauck's Tragicorum graecorum fragmenta apparently contains the beginning of the drama.

SOSNOWIEC, a town of Poland, in Slask province. Pop. (1946) 77,853. It owes its importance to its position in the centre of Dabrowa coal field, near Bedzin, Dabrowa and Katowice. The towns of this region are almost continuous, extending from Kielce into the provinces of Kraków and Slask. Sosnowice is also a railway junction. Situated on the Warsaw-Vienna railway, it is a junction for the Kielce and Radom, Kraków and Lvov and Katowice and Breslau lines. Electric power stations were established. Iron foundries and textile factories, as well as coal mines, employ large numbers of workmen. Sosnowice was seized by Germany in World War II and was returned to Poland in 1945.

SOSTENUTO, musical term signifying that the passage so marked is to be played in a "sustained" manner.

SOTADES, Greek satirist, of Maronea in Thrace (or of Crete), chief representative of the writers of coarse satirical poems, called κίναιδοι, composed in the Ionic dialect and in a metre named after him "sotadic." He lived in Alexandria during the reign of Ptolemy II Philadelphus (285–247 B.C.). Sotades was imprisoned for a satire on Ptolemy, escaped to Caunus, was captured, shut up in a leaden chest and thrown into the sea.

Only a few genuine fragments of Sotades have been preserved (see J. G. Hermann, Elementa doctrinae metricae, 1816).

SOTER, pope from about 167 to 174. He wrote to the Church of Corinth and sent it aid. His letter is mentioned in the reply given by Dionysius, bishop of Corinth, and Harnack thinks it can be identified with the second so-called epistle of Clement.

SOTHERN, EDWARD ASKEW (1826-1881), English actor, was born in Liverpool on April 1, 1826, the son of a merchant. After acting in the English provinces, he went to the United States in 1852. There he made a great success in New York in 1858 as Lord Dundreary in Tom Taylor's Our American Cousin. He created the title role in T. W. Robertson's David Carrick (1864) and also made a hit as Sam Slingsby in John Oxenford's Brother Sam (1865). He died in London Jan. 21, 1881.

SOTHERN, EDWARD HUGH (1859-1933), American actor, was born at New Orleans on Dec. 6, 1859, the son of Edward Askew Sothern, noted English comedian. His first stage appearance was in a small part with his father's company at the Park theatre in New York city in 1879. He toured England in 1882-83, became leading comedian in McCullough's company in 1883, and under Daniel Frohman was leading man at the Lyceum theatre in New York city. He married Virginia Harned in 1896, and in 1899 formed his own company with her as his leading lady.

In 1900 he appeared in the title role of Hamlet, in 1901 in that of Richard Lovelace and in 1902—03 as Villon in If I Were King, three of his greatest roles. In 1904 he entered into combination with Julia Marlowe, the two first appearing together in Romeo and Juliet at Chicago. Except for two years, 1907—09,

appear that the physical basis of the theory of sound involves (s being the force required to produce unit displacement). Thus three fundamental considerations. First a vibrating body is essential to the production of sound; second, an elastic medium in contact with the vibrating body is required to transmit the vibrations to a distant point; and third, some form of receiver is necessary to absorb the energy from the medium and to reconvert it into a form of vibratory motion convenient for observation. We shall follow this order of treatment as far as practicable.

#### SOURCES OF SOUND

Vibrating Systems .- A fundamental advance in the theory of sound was made in 1843 when Georg Ohm proved that the simplest and most fundamental type of sound sensation is that which corresponds to a simple harmonic motion, i.e., to the simplest mathematical form of periodic function.

Such motions may vary in period and amplitude but in no other manner; they are consequently ideal for the production of "simple" or "pure" tones. Another important feature of this form of motion is the possibility of transmission from one medium to another without change of form. Again, it has been proved by J. B. J. Fourier that the most complex form of periodic motion can be analyzed (or synthesized) into a series of simple harmonic motions having frequencies which are multiples of that of the complex motion. The vibrations of a tuning fork may approximate closely to a simple harmonic motion, the resulting sensation being described as a "pure tone."

Simple Harmonic Motion is typified by the oscillations of a particle attracted toward a fixed point O with a force varying as the distance x from O. If s be the force at unit distance from O, then at x it will be -sx, the sign of the force being always opposite to that of the displacement. Thus if m is the mass of the particle

$$m^{\partial 2x}/\partial t^2 = -sx$$
 or, writing  $n^2 = s/m$ ,  $\partial^2 x/\partial t^2 + n^2x = 0$ 

of which the solution is

$$x = a \cos(nt + \epsilon)$$
 (2)

the constants a and  $\epsilon$  are arbitrary. The motion is therefore periodic, the values of the displacement x, and the velocity  $\partial x/\partial t$  of the particle recurring whenever nt increases by  $2\pi$ . The periodic time of the oscillation is therefore

$$T = 2\pi/n = 2\pi\sqrt{(m/s)} \tag{3}$$

a quantity independent of a. The type of vibration indicated by equation (2) is of fundamental importance. The equation shows that the particle oscillates between two points at a distance a on opposite sides of O. This distance a is called the amplitude of the vibration. The quantity e represents the initial phase of the vibration when t=0. By simple differentiation of equation (2) coordinate the velocity of the particle  $\partial x/\partial t = -an \sin(nt+\epsilon)$  and the acceleration  $\partial^2 x/\partial t^2 = -n^2 x$  as postulated in equation (1). The meaning of equation (2) for S.H.M. is often expressed graphically as the projection on a diameter of the motion of a point moving uniformly, with constant angular velocity n on a circular path of radius a, the periodic time (for one revolution) being  $T = 2\pi/n$ . The reciprocal of the period T, viz.,  $n/2\pi$ , is termed the frequency. The quantity n is sometimes called the pulsatance.

Practical demonstration of the relation between a simple harmonic motion and the corresponding circular motion may be seen in any type of reciprocating engine; the motion of the piston in the cylinder is approximately simple harmonic while that of the flywheel is circular with uniform velocity. A simple pendulum, a weight suspended on a spring, a rapidly vibrating wire, tuning fork or diaphragm all illustrate, approximately, simple differences in frequency and amplitude only.

The relationship (3) for the periodic time of vibration is of very de application in the theory of sound. It indicates the general

Order of Treatment. - From what has already been said it will factor m and decreases with the "stiffness" or "elastic factor" s in the case of a simple pendulum of length l, s = mg/l, from which the periodic time of an oscillation is  $T = 2\pi\sqrt{(l/g)}$ . The period of vibration of a mass m on a helical spring of strength s is expressed directly by (3), viz.  $T = 2\pi\sqrt{(m/s)}$ . We also obtain from (2), for the energy of the vibrating particle

Mean kinetic energy = Mean potential energy = ma?n2/4

Maximum energy =  $ma^2n^2/2$ .

The energy is a maximum at the mid-point and at the two turning points of the vibration. In the former case it is all kinetic and in the latter all potential energy.

When a single particle is acted on by a number of distinct forces, each of which would cause it to perform S.H M., the question arises as to the resultant motion A number of important cases require consideration: - I. Vibrations of the same frequency and in the same straight line It may be shown that such a system of vibrations is reduced to a single resultant by means of a vector polygon, the angles representing relative phases, in exactly the same manner as a system of forces acting at a point. II. Two vibrations of nearly the same frequency and acting in the same straight line: beats. This case has very important applications in sound and is of frequent occurrence. If two vibrations of the same amplitude and nearly equal frequency act together the resultant amplitude will at first be double the single amplitude. As the higher frequency vibration gains on the lower, however, thereby changing the relative phase, a point will be reached when they are in opposition and will neutralize each other (amplitude zero). This cyclic process goes on so long as both vibrations are maintained. If the two frequencies are N and  $N+\partial N$ , the resultant amplitude will vary between 2a and o, the time interval between two successive maxima being  $2\pi/\partial N$ , i.e., the frequency of the beats will be  $\partial N$ , the difference between the two, nearly equal, frequencies. The phenomenon of beats is observed when two notes nearly in tune are heard together - a periodic rise and fall of intensity being noticed. As the beats between two notes increase in frequency a sensation of roughness or discord (dissonance) sets in, and ultimately two independent notes of the diatonic scale are recognized. The beat effect has direct application in the comparison of one sound frequency (e.g., that of a vibrating string) with a standard of frequency such as a tuning fork. The well-known heterodyne of radiotelegraphy or telephony is a heat effect between two sets of radio-frequency (e.g., 106 cycles per second) oscillations, slightly mistuned. The beat-note is adjusted to have any frequency, say 500 periods per second, which falls within the audible range. III. Vibrations at rightangles. In this case we are dealing with the motion of a particle on a plane surface. When the imposed vibrations have the same frequency, it is readily shown that the particle traces an elliptical path, which may vary from a straight line, when the phases differ by 180°, to a circle when the phases differ by 90° and the amplitudes are equal. (a). Frequencies nearly equal. In this case the particle follows a path which slowly changes through the various forms, straight line, ellipse, circle, etc., due to the slowly changing phase difference. The frequency of performance of a complete cycle of figures will, of course, be  $\partial N$ , the difference between the two nearly equal frequencies. (b). Frequencies commensurate. 2:1, 3:1, 4:1, etc. Here again the particle traces out a curve having a certain number of Loops—this number being equal to the ratio of frequencies. For nearly commensurate frequencies the curve slowly changes as the phase difference varies. Numerous mechanical devices have been designed for drawing automatically the various "harmonic" curves obtained by compounding two or more harmonic vibrations. These generally consist of two compound pendulums controlling a common writing point, and each capable of performing simple harmonic motion; any differences in their motion arising from harmonic motion in one or possibly two directions simultaneously. Beautiful and fascinating designs may be traced in this

An optical method of exhibiting a small difference of frequency ale that the period T increases with the "inertia" or mass between two tuning forks was devised by J. A. Lissajous (18221880). A small mirror is attached to one prong of each fork, one of which vibrates in a vertical plane and the other horizontally. A narrow pencil of light is reflected successively from the two mirrors and falls on a screen. When the forks vibrate together the spot of light on the screen traces out the "resultant" curve of the two vibrations. If the two forks have the same frequency the figure is a stationary ellipse; if they differ slightly in frequency, the ellipse assumes successively the various forms including a straight line and a circle. These figures are known as Lissajous figures. The same principle may, of course, be applied to any two systems vibrating at right angles with approximately equal, or commensurate, frequencies. Recently Dye has employed the cathode-ray oscillograph for the harmonic comparison of very high electrical frequencies (of the order role p.p.s.).

Fourier's Theorem.—Summation of any number of simple harmonic-vibrations of commensurate frequencies. Synthesis and analysis of complex wave-forms of vibration. This very important theorem due to J. B. J. Fourier (Theorie de la Chaleur. Paris, 1822) asserts that any single-valued periodic function whatever can be expressed as a summation of simple harmonic terms having frequencies which are multiples of that of the given function. (See Harmonic Analysis.) The theorem not only deals with the synthesis of a complex form of vibration, but also indicates a method of analysis of such a vibration into its component simple vibrations or harmonics. Thus if x is the resultant displacement at a time t, in a complex vibration of frequency n/2\pi,

$$x = f(nt) = A_0 + A_1 \cos nt + A_2 \cos 2nt + \dots + A_r \cos(rnt) + B_1 \sin nt + B_2 \sin 2nt + \dots + B_r \sin(rnt).$$
(6)

By suitable choice of the amplitude-values  $A_0$ ,  $A_1$ , etc.,  $B_1$ ,  $B_2$ , etc., it is possible to analyse or synthesise any form of single-valued periodic vibration. Thus the displacement curve represented by fig. 1 (a), may be obtained by adding a sufficient number of odd terms of a sine series. In fig. 1 (b) the first, third and fifth terms are added, in fig. 1 (c) the first fifteen odd sine terms are added. It will be seen that (c) approximates closely to (a), the more terms taken the more nearly does the synthesised curve approach the ideal. The mathematical analysis or synthesis of complex wave-forms may become very laborious. In order to simplify the process various mechanical "harmonic analyses" have been constructed (see Millar's "Science of Musical Sounds") which perform the necessary mathematical integrations, by a direct mechanical process. Fourier's theorem and harmonic analysis have a wide field of application not only in the study of sound-vibrations, but in astronomy, meteorology,

tide prediction, mechanical and electrical engineering.
Loudness, Pitch and Quality. Intensity, Frequency and
Wave-form.—Sounds differ from one another in three respects.

(i) Londness and Intensity.—These two terms refer to the subjective and physical aspects respectively. The intensity of a sound refers to a definite physical quantity which determines the rate of supply of vibrational energy (proportional to [amplitude]). Londness corresponds to the degree of sensation, being

dependent both on the intensity of the sound and the sensitiveness of the ear under the particular conditions. Near the limits of audibility loudness may be very feeble although the intensity be very great. The sensation of loudness varies over a relatively small range for enormous variations of intensity. An ear which can detect a feeble watch tick remains undamaged by a neighbouring explosion—although the range of intensity involved in these examples may be greater than rol<sup>22</sup> to r. The relation between sensation (loudness) and stimulus (intensity or amplitude) is generally expressed by Weber's law—"The increase of stimulus

necessary to produce a just perceptible increase of sensation is proportional to the pre-existing stimulus." This law indicates a rapid diminution of sensitiveness of the ear with increase of total intensity of the sound.

(ii) Pitch and Frequency. - The frequency of a regular or periodic vibration is the number of vibrations performed per second. Musical sounds arrange themselves in a natural order according to pitch. The latter depends solely on the predominant frequency of the vibrations-the greater this frequency the higher the pitch-and on the number of these vibrations reaching the ear per second. The latter stipulation is made to include sounds received from sources of sound in motion. This relation between pitch and frequency is simply verified by means of a revolving toothed wheel striking the edge of a card which produces a sound whose predominant frequency is proportional to the product of speed (revolutions per second) and the number of teeth on the wheel. For a given note the predominant frequency is the same whatever the source of the note, and the ratio of the frequencies of two notes forming a given musical interval is the same in whatever part of the musical range the two notes are situated. The more important consonant intervals with their frequency ratios are Unison 1:1, Major Third 5:4, Fifth 3:2, Major Sixth 8:5, Minor Third 6:5, Fourth 4:3, Minor Sixth 5:3, Octave 2:1. Notes whose frequencies are multiples of that of a given one the fundamental, are called harmonics. The frequency ratios defining each note of the diatonic musical scale are

The same series of ratios applies to any octave which may be chosen.

(iii) Quality and Wave-Form.—Sounds of the same pitch and loudness, but produced by different means, are distinguished by their quality. Thus the same note produced by a voice, a piano, or a violin, would have distinct characteristics which are at once recognisable by the ear. Very few sounds can be regarded as "pure," that is, free from overtones. The presence or absence of these overtones decides the quality of the sound. A tuning fork emits almost a pure tone whereas a violin note is rich in overtones characteristic of the instrument. Quality depends therefore on wave-form. Fourier's analysis of the wave-form of the sound emitted by a particular instrument tells us which harmonics are present and their relative importance.—On account of

Forced Vibrations, Damping, Resonance.—On account of the dissipation of energy by forces of a frictional nature, a vibrating body if left to itself, is gradually brought to rest. Its vibrations may be maintained, however, by the application of a suitable periodic force, which supplies the energy dissipated by friction and sound radiation. It is important to consider the relation between the frequency of such a force and the frequency of the free or natural vibration of the body. It is generally assumed that for small oscillations the frictional forces are proportional to the velocity of the particle. Consequently the equation of forces becomes

$$m\frac{\partial^2 x}{\partial t^2} + r\frac{\partial x}{\partial t} + sx = F\cos pt \tag{7}$$

where F cos pt represents the external periodic force of maximum value F and frequency  $p/2\pi$ , r is the resistance per unit velocity and s the restoring force per unit displacement. Writing  $s/m=n^2$ , F/m=f and r/2m=k it can be shown that the displacement x' is given by

$$x = \frac{f \sin \epsilon}{2kp} \cos(pt - \epsilon) \quad \text{where} \quad \tan \epsilon = \frac{2kp}{(n^2 - p^2)} \tag{8}$$

representing the forced vibration of period  $p/2\pi$  and amplitude  $f\sin e/kp$ . In the case where there is no friction, the damping constant k=0,  $\sin e=\tan e=0$ , e=0 or  $\pi$ , and

Amplitude of Forced Vibrations. —In the steady state of maintained oscillations, equations (8) and (9) represent the resultant forced motion. The amplitude A of the motion, is given by

$$A = \frac{f \sin \epsilon}{2kp} = \frac{f}{\{(n^2 - p^2)^2 + 4k^2\hat{p}^2\}^{\frac{1}{2}}} \left( \text{Since } \sin \epsilon = \frac{2kp}{\{(n^2 - p^2)^2 + 4k^2\hat{p}^2\}^{\frac{1}{2}}} \right)$$

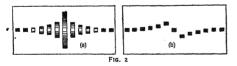

This expression is of fundamental importance. The amplitude A is a maximum when the denominator of the expression is a minimum, i.e., when  $p^2 = n^2 - 2k^2$  (provided  $n^2 > 2k^2$ ); the maximum value being then

$$A_{\max} = f/2kn. \tag{11}$$

In the case where there is no damping (k=0), and the free frequency n is the same as the forced frequency p, it will be seen that the amplitude A becomes infinite. Such a case of course never occurs in practice, for the damping k is never zero. For moderate values of damping  $(n^2 > 2k^2)$ , the forced amplitude  $A_{\max}$ . (equation [11]) is greatest when the forced frequency coincides with that of the free vibration, and may become very large when k is small. This condition is known as resonance. When dealing with sources of sound, we shall have occasion to refer frequently to resonant vibrations.

Phase of Forced Vibrations .- The force and the resultant forced vibrations are not necessarily in phase. From equation (8) we see that tane is always positive when p is less than n, that is  $\epsilon$  lies between o and  $\pi/2$  when the forced frequency is less than the free frequency, and tane is always negative when p is greater than n, that is,  $\epsilon$  lies between  $\pi/2$  and  $\pi$  when the forced frequency is greater than the free frequency. At resonance, when n=p,  $\tan\epsilon=\infty$  and  $\epsilon=\pi/2$ , i.e., the force and the displacement are "in quadrature" whilst the force and velocity are "in phase." Away from resonance, if the damping is small, the phase difference e will, in general, be nearly equal to o or to π, that is, the displacement will be in phase or out of phase with the force according as the frequency of the force is less or greater than the frequency of the free vibrations. These phase effects are beautifully demonstrated by means of a frequency meter of the vibrating reed type, viewed intermittently at, or very near, the frequency of excitation. The graduated series of reeds appear as in fig. 2 (a) when viewed in the ordinary way, but as in fig. 2 (b) when viewed intermittently. In accordance with the theory, the reeds on opposite sides of the resonant one are seen to be in opposite phase, with the resonant reed intermediate.

Power Dissipation.—In order to maintain vibrations against damping forces, a certain rate of energy supply is necessary. This is measured by the product of the force  $f \cos pt$  and the

particle velocity  $\partial x/\partial t$  (obtained by differentiating equation [2] with respect to t). The mean power required to maintain vibrations is thus found to be

$$W = \frac{f^2}{4k} \cdot \sin^2 \epsilon \tag{12}$$

This reduces to zero when  $\epsilon=0$  or  $\pi$  i.e. when k=0 (see equation [10]). In the case of damped vibrations at resonance the power dissipation is a maximum for

$$\epsilon = \pi/2$$
, whence  $W_{\text{max}} = f^2/4k$  (13)

Sharpness of Resonance.—The effect of damping becomes relatively more and more important as resonance is approached. At resonance the amplitude and power dissipation reach a maximum. The ratio of power dissipation W under specified conditions to that at resonance is given by

$$\frac{W}{W_{\text{max.}}} = \sin^2 \epsilon = \frac{4k^2}{\left(\frac{n^2 - p^2}{4}\right)^2 + 4k^2} \quad \text{[from (4)]}$$
 (14)

a relation indicating how the power required to maintain vibrations against frictional and radiation losses varies near resonance. It will be seen from (14) that the energy dissipated at a frequency  $p/2\pi$ , near resonance, is half the resonance value when

$$\left(\frac{n^2-p^2}{p}\right)^2 = 4k^2$$

that is when

$$(n-p)=\pm k$$
 (approx.) or  $\frac{p}{n}=1\pm \frac{k}{n}$ , (15)

i.e., when the frequency of the force differs from that of the resonator by the fraction k/n. This ratio k/n therefore constitutes a measure of the sharpness of resonance. The reciprocal of the ratio, i.e., n/k is sometimes referred to as the "persistence" of the vibrations. The smaller the damping k and the higher the natural frequency n, the sharper will be the tuning, and the greater the persistence of the vibrations. This principle has many striking and important applications. Thus in frequency standardisation, e.g., of tuning forks or quartz resonators, very great accuracy of tuning is essential, and the damping must be extremely small. In other cases, e.g., the faithful reception or reproduction of sound vibrations over a range of frequencies, resonance is distinctly undesirable, and the system must have a natural frequency  $(n/2\pi)$  removed as far as convenient from any possible values of the forced frequency  $(p/2\pi)$ , or, alternatively, the system must be heavily damped (k | k rge).

The damping constant k of a vibrating system is determined by direct measurement of the rate of decay of its free oscillations (from  $A_2=A_1e^{-k\tau}$ , or  $\log A_1/A_2=k\tau$  where  $A_1$  and  $A_2$  are successive amplitudes on the same side and  $\tau$  is the periodic time  $-k\tau$  is known as the logarithmic decrement of the oscillations). The damping coefficient k may be determined alternatively from observations of the sharpness of resonance.

Electrical Oscillations .- Alternating electrical and magnetic effects provide a very convenient means of exciting the corresponding mechanical vibrations. The advent of the thermionic three-electrode valve, as a simple means of producing electrical oscillations over a wide range of frequency and power, has greatly assisted in the rapid development in the design of electrical sound sources, and in electrical methods of receiving and recording sound waves. There is a close analogy between electrical and mechanical oscillations. If we replace inertia (mass) m in the mechanical system by inductance L in the electrical system, mechanical resistance r by electrical resistance R, spring factor (or stiffness) s by r/capacity (1/C), displacement x by quantity Q, velocity  $\partial x/\partial t$  by current  $i=\partial Q/\partial t$ , acceleration  $\partial^2 x/\partial t^2$  by rate of change of current  $\partial^2 Q/\partial t^2$ —the electrical equations become identical with the corresponding mechanical equations. Thus the electrical equation for the forced oscillations of a circuit containing inductance L, capacity C, and resistance R, is

$$L\frac{\partial^2 Q}{\partial x} + R\frac{\partial Q}{\partial t} + \frac{Q}{C} = E\cos pt \tag{16}$$

which is analogous to equation (7) for a mechanical system. With the substitutions mentioned above (with  $k\!=\!L/2R$  and  $f\!=\!E/L$ ) the solution of this equation is similar to equation (8) and the subsequent remarks relative to resonance and damping apply also to the electrical system. The frequency of free vibra-

tion of a mechanical system is  $N = \frac{1}{2\pi} \sqrt{(m/s)}$  (see equation [3]),

and the corresponding frequency of electrical oscillations is  $N = \frac{1}{2\pi} \sqrt{LC}$ . This is also the frequency at resonance in the case of forced vibrations provided the damping k and resistance

R are not excessive.

For the various methods of generating alternating currents, (e.g., by valve oscillators, interrupters, alternators, etc.) the reader should consult the article on Wireless Telegraphy.

Motional Impedance.—On account of the extensive use of electrical forms of sound generators and receivers it is very important in design to have a knowledge of their characteristics. In any form of machine which converts electrical energy into motion the moving mechanism reacts on the electrical circuit. Thus the revolving armature of an ordinary electric motor generates what is called a back e.m.f. in opposition to the applied voltage. This back e.m.f. may alternatively be regarded as an increased resistance to current flow in the armature, the efficiency of the motor being measured by the ratio of this resistance R relative to the total resistance (R+r) in the circuit; the net power used in the motor being a maximum when R=r, in which case the efficiency is 50%. In a similar manner the mechanical vibrating element of an electrical sound generator or receiver reacts on the electrical circuit, the back e.m.f. due to the vibration appearing as a change of impedance of the circuit. The change of impedance due to this cause is termed motional impedance and, relative to the total impedance, is a measure of the efficiency of the sound generator.

Transverse Vibrations of Strings.—When any point of a thin flexible wire stretched between two fixed clamps or bridges is displaced transversely and released, the wire commences to vibrate. This vibration results from transverse motions travelling in opposite directions along the string and successive reflections of these motions from the fixed ends. In order to visualize such reflection of a transverse motion it is well to make a few simple experiments on waves travelling along a stretched rope, one end of which is held in the hand while the other end is fixed. It will be observed that the movement of each particle of the rope when forming part of the reflected wave is in the opposite direction to its motion in the original wave. The rope assumes the form of a sine wave if the end is moved up and down harmonically. Before we can deduce the modes of vibration of a stretched string it is necessary to know the velocity with which a wave of displacement travels along the string and also the manner in which the direct and reflected waves affect each other to produce what are called stationary waves.

Velocity of a Transverse Wave Along a String.— The following method is due to Tait. The string is supposed to be drawn through an imaginary smooth tube with velocity c. The tube is straight except for an isolated curved portion which represents the wave on the string. If R is the radius of curvature at any point of the tube, the force acting in the direction of the normal to an element  $\delta s$  is  $T\delta s/R$  where T is the tension in the string. Now the centrifugal force of the element  $\delta s$ , of mass m per unit length, and velocity c will be  $m\delta s c^2/R$ , and this must balance the force  $T\delta s/R$  if there is to be no reaction on the tube. Thus if  $T\delta s/R = m\delta s \cdot c^2/R$ , then  $c = \sqrt{(T/m)}$  and there is no reaction on the tube, i.e., the tube may be regarded as absent and the wave travelling along the string with the velocity  $c = \sqrt{(T/m)}$ .

Reflection. Formation of Stationary Waves.—If both ends of the string of length l are fixed, the wave is reflected successively from end to end, and the resultant motion is determined by the superposition of the direct, or incident wave, and the reflected wave. The resultant displacement y at the instant t of a point distant t from one end will be y=f(t-x)-f(t-t), where f indicates "a function of." Since y=0 when x=l we have also f(t-l)=f(t+l), or f(z)=f(z+z) where z=(t-l), which indicates that z is periodic function repeating at intervals of zl. Consequently the c isplacement at any point of the string is periodic, the period T=zl/c being the time taken for a wave to travel along the full length of the string and back again. The frequency of this form of vibration is consequently N=c/zl where  $c=\sqrt{(T/m)}$ , i.e.,

$$V = \frac{1}{2l} \sqrt{\frac{T}{m}}.$$
 (17)

If the displacement y varies sinusoidally with a frequency  $n/2\pi$ ,

we have y=sa cos n(t-x/c)-a cos n(t+x/c) which reduces to y=2a sin  $nt\cdot\sin(nx/c)$ . (18)

At any point x on the string the amplitude is therefore  $2a \sin nt$ , varying sinusoidally with time between zero and 2a. The amplitude of successive particles is also varying with x according

to a sine law. The result is a series of loops on the string of amplitude o to 2a. The condition for the formation of loops on a string of finite length l is clearly that in which l is a whole multiple of the length of a loop, i.e., provided the number of loops is  $1, 2, 3, \ldots$  etc. The fundamental frequency n of the string is given by (17), the various possible overtones are simple multiples of n, i.e., they form a harmonic series. The modes of vibrating with 1, 2, 3 loops is shown in fig. 3. The points marked n, which are permanently at rest during the vibrations, are called nodes, while the points marked n where the amplitude is a maximum are called antinodes or loops. It will be evident that the string could be clamped at the nodes n without affecting the motion of the remainder of the string. Denoting the wave length of the vibration by  $\lambda$  we must have  $N'\lambda = c = \sqrt{(T/m)}$  whence the frequency

$$N' = \frac{s}{2l} \sqrt{\frac{T}{m}} \tag{19}$$

s being the number of loops, *i.e.*, half wave lengths, into which the string of length l is divided.

The string may vibrate with any of the frequencies given by equation (19) at the same time, i.e., a note may be produced which is made up of the fundamental and a number of harmonics. The laws of a vibrating string indicated by equation (19) may easily be verified by means of a monochord or sonometer, which consists essentially of a thin metallic wire (e.g., steel piano wire) stretched over two bridges by means of a weight hanging over a pulley, or by a spring tensioning device. A movable bridge provides a convenient means of varying the vibrating length of the wire. The monochord is a very useful means of comparing frequencies-the frequency of the string being inversely proportional to the vibrating length. Exact tuning is indicated by the "beats" between the monochord note and the note compared with it. The various overtones of a string may also be very simply demonstrated by means of the monochord, the string being lightly damped at any point corresponding to a node and plucked or bowed at a point corresponding to an antinode of the overtone required to be excited. The positions of the antinodes are easily determined by means of little paper riders.

Stiffness of Strings and Yielding of Supports.—When the thickness of the string becomes appreciable in relation to the length of a loop, the stiffness may have a perceptible effect on the frequency of vibration—this effect becoming more and more important the higher the overtone excited (i.e., the greater the number of loops). Where great accuracy is required a modification of equation (10) is necessary, viz.

$$N = \frac{s}{2l} \sqrt{\frac{T}{m} \left\{ 1 + \frac{\pi^3 s^2 r^4 E}{8l^2 T} \right\}}$$

where r is the radius of the circular section of the wire and E Young's modulus of elasticity for the material. Yielding of the bridges supporting the wire may have the effect of increasing or decreasing the frequency according as the supports have (a) very large mass M but small spring factor or (b) very large spring factor  $\mu$  and negligible mass. The effects of (a) and (b) are equivalent to a change of length of the string in the radius  $x:(x-2TI/Ma^2s^2\pi^2)$  and x:(x+2T/MI) respectively.

Methods of Producing Vibration in Strings. Quality.-A stretched string may be set in vibration by numerous methods. Plucking, bowing and striking are the more familiar; exemplified in the harp, the violin, and the piano, respectively. A string may also be set in vibration by forced oscillation of a point of support, e.g., if one end is attached to the prong of a vibrating tuning fork (Melde's experiment). Electromagnetic methods may also be used to excite a metallic string. In one of these methods a light metal wire is attached at right angles to the vibrating wire and arranged to dip in a small cup of mercury at each downward movement. A current passing through this intermittent contact actuates a small electromagnet which maintains the wire in vibration in the same manner as an electric bell is operated. In another method the vibrating wire itself carries an alternating electric current and lies in a permanent magnetic field. When the frequency of the current and position of the magnet are suitably chosen one of the numerous possible overtones of the wire will be readily excited. It will be appreciated that the method of excitation has a very important influence on the form of the wave which travels along the string. The quality of the note is of course dependent on this wave form, i.c., on the relative amplitudes of the various overtones present in the vibration. It is just this addition of overtones to the fundamental which makes it possible for the ear to distinguish between the sounds of a piano, a violin, and a harp, emitting the same fundamental note.

Strings as a Source of Sound: The Sounding Board.—A vibrating wire rigidly supported would radiate extremely little sound energy to the surrounding air on account of the local reciprocating flow of air between opposite sides of the vibrating wire. It is necessary in an efficient stringed sound source that the bridges should yield and communicate the vibrations to a surface of large area, i.e., to a sound board, in contact with the medium. This sound board is therefore a vital part of all stringed musical instruments—it is important, however, in a good instrument, that the sounding board should have no predominant resonance frequencies of its own, otherwise these would reinforce dispropor-

tionately the corresponding frequencies of the strings.

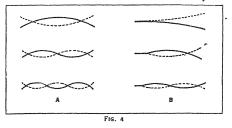

Transverse Vibrations of Elastic Rods.—The vibrations of a stretched wire are controlled by the tension whilst the stiffness of the wire may generally be disregarded. In the case of a relatively thick wire or rod the stiffness may become all-important and tension may ultimately be disregarded. Even when simplified as far as possible the theory of transverse vibrations of elastic rods is very complex in comparison with the theory of strings. In the case of strings, harmonic waves travel with a velocity independent of wave-length but in the case of rods or bars this is not so. It is shown in textbooks of sound (see Bibliography) that the velocity of a transverse elastic wave in a rod is proportional to  $t \cdot \sqrt{(E/\rho)} \cdot / \lambda$  where t is the thickness in the direction of displacement, E elasticity,  $\rho$  density, and  $\lambda$  the wavetength. The velocity is thus dependent on the wavelength, a fact which makes the theory much more complex. It may be shown that the possible frequencies of transverse vibration of a bar are given by

$$N = C \frac{k}{P} \sqrt{\frac{E}{\rho}} \tag{20}$$

where k is the radius of gyration of the section of the bar about the neutral plane, and l is the length of the bar  $(k^* = P/lz)$  for a rectangular bar of thickness l. The value of the constant C depends on the method of supporting or clamping the bar and on the overtone to be excited. The frequency is therefore proportional to the velocity of longitudinal waves  $\{(E/p)\}$  in the material of the bar. It also varies as the thickness (or radius) and inversely as the square of the length of the bar. As in the case of strings, stationary waves are set up in rods by the combined effects of the direct and reflected waves. The possible forms of these stationary waves depend on the method of supporting the rod. Some of the modes of vibration of a free-free rod, i.e., entirely tree or supported at two nodes, are shown in fig. 4a; whilst the self-actionary these bar, i.e., a bar fixed

in direction at one end and free at the other.

In the case of the free-free bar the constant C in equation (20) for the frequency is equal to  $\frac{\pi}{8}(4s\pm 1)^2$  where s may be 1,2,3,3 etc. i.e., the possible frequencies are proportional to the squares of the successive odd numbers commencing at 3. For a clambed-free bar the constant C in equation (20) is approximately equal to  $\frac{\pi}{8}(4s\pm 1)^2$  where s may be 0, 1, 2, 3, etc. More accurate values for  $(4s\pm 1)$  in the case of the fundamental (s=0) and the first overtone (s=1) are 1-1037 and 2-9884 respectively. The

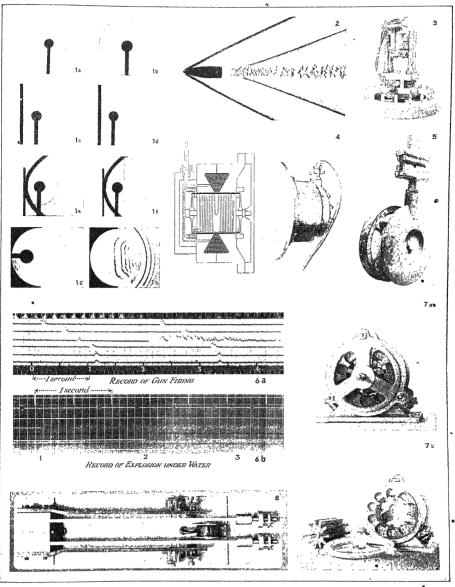

frequencies of the first three tones relative to the fundamental are consequently 1, 6-25 and 17-6 approximately. The relation  $N \subset k \cdot d(E/\rho)/P$  has been experimentally verified by a number of physicists, both in the case of the free-free and the clamped-free

Applications and Methods of Excitation .- As in the case of strings the transverse vibrations of a bar may be excited by striking, plucking, bowing, or by electromagnetic means, the partials present, and consequently the quality of the note being dependent on the method of excitation. The only method of supporting a bar which yields "harmonic partials" is the freefree method, which has application in a musical instrument known as the "harmonicon" or "dulcimer" in which freely supported bars of graded lengths are struck by a hammer, thus producing an agreeable succession of musical tones. Thin rods or reeds, clamped at one end and excited by plucking, are used in the "musical box" so well known. Used in combination with suitable air cavity resonators, clamped-free reeds are fitted in various musical instruments, notably the clarinet group. The combined action of an air blast and a vibrating reed is illustrated in the concertina and the harmonium, whilst in the reed pipes of an organ the reed is combined with a resonant air column. The reed of the telephone earpiece designed by S. G. Brown is operated electromagnetically. It is used in an almost unstable condition, the pull of a permanent magnet being nearly sufficient to overcome the stiffness of the reed. This results in a large increase of sensitiveness to the superposed alternating magnetic field.

sensitiveness to the superposed atternating magnetic item. Frequency Moters form a good example of the electro-magnetic or direct mechanical excitation of reeds. The frequency meter consists essentially of a graded series of clamped steel reeds actuated by a common electro-magnet supplied with alternating current of which the frequency is required. Such instruments have been made covering various ranges from 1 or 2 to 1,500 cycles per second. The frequency of a clamped-free bar may be lowered either by loading the free end or by reducing the cross section near the clamped end. The frequency may be raised either by shortening the bar or reducing the cross section near the free end.

Tuning Forks.—On account of its great purity of tone and constancy of frequency the tuning fork is generally regarded as a standard of frequency and pitch. During recent years it has increased enormously in importance as a frequency standard for controlling electrical circuits, in such a manner as to form an electrical standard of great accuracy and of extensive range.

- Spark-Shadow Photographs illustrating reflection from plane and curved surfaces. (Figs. a to f by A. L. Foley; g & h are comparative spark and ripple photographs by A. H. Davis)

- Fessenden Oscillator
- Fig. 5. Directional Hydrophone
- Sound-ranging records (a) Army, (b) Navy Phonic Motor (a) assembled, (3) in parts
- Fig. 8. Electrically-maintained Tuning Fork

The tuning fork may be regarded either as a development from a free-free bar bent into the form of a U, or as consisting of a bair of symmetrical clamped-free bars attached to a common block of metal. Numerous patterns are in existence approximating to one or other of these two forms. It will be sufficient here to regard each prong as a clamped-free bar. In consequence of the oscillation of the centre of gravity of the two bars as they vibrate there will be communication of vibration to the block to which they are clamped. To reduce the amplitude of this vibration, which is in the direction of the prongs, the block must be firm and massive. The frequency of a fork of this construction with prongs of rectangular section of thickness t will therefore be

$$N = (1.1937)^{2} \cdot \frac{\pi}{8} \cdot \frac{t}{\sqrt{12.12}} \sqrt{\frac{E}{0}}$$
 (21)

that is,  $N=8\cdot24\times 10^4/l^2$  if the prongs are of steel in which  $\sqrt{(E/\beta)}=51\times10^6$  cms /sec. The frequency of a fork will therefore vary directly as the thickness of the prongs and as the velocity of sound in the material, and inversely as the square of the length of the prongs. The first and second overtones of a fork will have frequencies  $6\cdot25N$  and  $17\cdot6N$  respectively. These overtones may easily be excited in a large fork by bowing at suitable points.

The fundamental tone of a tuning fork may be selectively reinforced by attaching the stem to a resonance box of the same frequency—the overtones of the fork and the air cavity are widely different and do not reinforce each other. Two forks of nearly the same pitch may be compared by the method of beats, which gives in a very simple and direct manner the difference in frequencies. This method is also useful in studying the effect of temperature on the frequency of a fork—the one fork is kept under standard conditions whilst the temperature of another is varied. The temperature coefficient of frequency for a steel fork determined in this way is approximately—10<sup>-4</sup> per degree C rise of temperature. The temperature coefficient of a fork made of elinvar steel is about one tenth of this.

Electrically Maintained Forks .- The vibrations of a lowfrequency fork may readily be maintained by means of electrical contacts controlled by the prongs and an electro-magnet situated between them. The mode of operation is similar to that of an electric bell. Forks of higher frequency (of the order of 1,000 p.p.s.) are maintained by means of electromagnets arranged in a special form of 3-electrode valve circuit devised by Eccles. Electrically maintained forks may be used to drive what are known as phonic motors (see Figures 7 and 8 on Plate), the vibratory motion of the fork being thereby converted into a rotary motion of combined accuracy and constant speed. Electrically maintained forks and phonic motors, with their applications in standard frequency determinations, are described in A. B. Wood's Textbook of Sound. Forks are now in common use as sub-standards of time. The period of a fork is a very constant quantity and serves as a convenient sub-division of a second when time intervals have to be measured with accuracy. As a consequence of the increased application of the tuning fork for this purpose, methods have been devised for increasing the accuracy and perfection of electrically maintained forks. Low-frequency forks of this character giving an accuracy greater than 1 in 10,000 are in common use. If particular care is taken with the choice of material, design, and control of the fork, an accuracy of 1 in 105 or even 1 in a million is possible.

Electrically maintained forks of this nature are used to control electrical "multi-vibrator" circuits which serve as frequency standards for all frequencies which are multiples of that of the fork, e.g., in steps of 1,000 cycles, up to 1.5 million cycles per second. The tuning fork thus functions as a standard of radio-frequencies. It is possible to maintain an electrically driven fork by means of the "seconds" contacts of a standard pendulum clock. Such clock controlled forks are not subject to temperature variations, etc., and remain accurately in step with the standard clock over relatively long periods of time.

Longitudinal Vibrations of Rods.—When a rod is set into longitudinal vibration its axis remains undisplaced whilst cross-

sections vibrate to and fro in the direction of the axis of the rod. The quantities involved are the density of the material and its elastic properties. Consider a rod of cross section A and an elementary slice of it bounded by two planes at x and  $x+\delta x$  at right angles to the axis x of the rod. If the plane at  $x \nmid \delta t$  sisplaced at the time t to  $x+\xi$  the plane at  $x+\delta x$  will be displaced to  $x+\delta x+\xi+d\xi/dx.\delta x$ , that is, the actual elongation of the slice is  $d\xi/dx.\delta x$  and its fractional elongation of  $d\xi/dx$ . This change in thickness of the slice implies a difference in the forces acting on its faces. The total force acting on the face at x will be  $EAd\xi/dx$  where E is Young's Modulus of elasticity. Similarly at the opposite face of the slice the force will be in the opposite sense and equal to  $EA(d\xi/dx-\delta x.d\xi/dx)$ . Consequently the resultant force acting on the slice will be  $EA.\delta x.d\xi/dx$ . Now the mass of the slice is equal to  $\rho A\delta x$ , where  $\rho$  is the density of the material, and the acceleration is  $d\xi^2/dx$ . We have therefore

$$\rho A \delta x \cdot \frac{d^2 \xi}{d l^2} = E A \frac{d^2 \xi}{d x^2} \cdot \delta x \quad \text{or} \quad \frac{d^2 \xi}{d l^2} = \frac{E}{\rho} \cdot \frac{d^2 \xi}{d x^2}$$
 (22)

an equation of the same form as that obtained for the transverse motion of a string, indicating a wave travelling along the rod with velocity  $c = \sqrt{(E/\rho)}$ . The above treatment is approximate only, since it ignores lateral bulging or contracting of the sides of the rod. The result is, however, sufficiently true provided the  $^{\rm flav}$  elength  $\lambda$  is great compared with the width or thickness of the rod. As in the case of vibrating strings the direct and end-reflected waves in a rod of finite length form stationary waves with nodes and antinodes in accordance with the relation

 $c=N\lambda=\sqrt{(E/\rho)}$  or  $N=\frac{1}{\lambda}\cdot\sqrt{(E/\rho)}$ . In the fundamental mode of vibration of a free bar  $\lambda=il$  and the various partials require  $s\lambda=2l$ . Consequently the expression for the frequencies of the partial tones is

$$N = \frac{s}{2l} \sqrt{\frac{E}{\rho}},\tag{23}$$

which is similar to equation (19) for strings, the tension T being now replaced by the elasticity E. When the bar is clamped at the mid point, an important practical case, all partials requiring an antinode at that point are suppressed, consequently only the odd partials are present. It will be seen that the partials given by (23), form a harmonic series—provided N/2 is always large compared with the diameter or thickness of the rod and that lateral bulging and shrinking may be neglected.

The frequency of longitudinal vibrations in bars is usually very high compared with that of the transverse modes, the ratio increasing rapidly as the diameter or thickness diminishes relative to the length. The nodes of a bar vibrating longitudinally are points of maximum stress, whereas the antinodes are points of zero stress. Biot and Tyndall demonstrated this fact to a large audience by means of passing polarised light through the node of a vibrating strip of plate glass. The analyser was set at extinction before the rod was set in vibration so that no light was seen on the screen. On stroking the rod with a resined cloth vigorous vibrations were set up and intermittent light was passed on to the screen. No such effects were observable at the antinodes where there is no stress.

Methods of Excitation.—Rods of metal, wood, or glass, clamped the midpoint or at one end, are readily set in vibration by the steady frictional drag of a resined cloth drawn, with a moderate pressure, along the rod towards an antinode. Another method, more suitable for relatively short stiff rods, is to strike the end a sharp blow with a hammer. This method usually results in a complex sound due to both transverse and longitudinal vibrations—the one or the other may be rapidly damped out by clamping at a suitable point.

Electrical Methods of Excitation.—Powerful longitudinal vibrations may be set up in bars of magnetic material by asting on them with alternating magnetic fields of the resonating frequency. Using a small alternating current magnet (with iron wire core) mounted close to the end of a steel bar, the fundamental and harmonics can readily be excited as almost pure tones. The resonance is extremely sharp (indicating very small internal damping) and careful tuning is required. Vibrations have been obtained in non-magnetic rods by electrostatic methods (J. H. Vincent, Natures. Dec. 31, 1927) the end of the vibrating rod forming one plate of a condenser supplied with high frequency alternating current from a valve oscillator. (See Ellectron Tube.)

Longitudinal Vibrations of High Frequency in Piezo-Electric Crystals.—Certain crystals, notably quartz and rochelle salt, have the property of changing their linear dimensions when subjected to electrostatic stress, and conversely they develop electrical charges on their faces when mechanically strained. The phenomenon is known as piezo-electricity (discovered by P. Curie, 1880). The best effects are obtained when slices or rods of the crystal are cut in certain specified directions relative to the optic axis. Voltage applied to the faces at the ends of the electric axis produces a change of thickness and length of the crystal. If alternating voltage is applied, the thickness and length fluctuate accordingly, the maximum effects being produced when the frequency of the electrical alternations coincides with the natural frequency of longitudinal elastic vibration. W. G. Cady (Phys. Rev., 19, p. 1, 1922) has made use of this property of a quartz crystal in the construction of standards of high frequency, with particular application to radio-frequency standardisation. A special electrical circuit which we need not consider here was employed to detect the resonance in the quartz. Thus Cady found that a quartz resonator 30x4x1.4 m.ms. vibrating longitudinally in the direction of its length had a fundamental frequency of 89,870 cycles per second. The tuning was so sharp that a change of frequency of 1 cycle per second was measurable. The overtones were also excited and found to approximate to harmonics of the fundamental. G W. Pierce (Proc. Amer. Acad., Vol. 59, Oct. 1923 and Vol. 60, Oct. 1925) has succeeded in controlling the frequency of an oscillating valve by means of such a crystal. In this manner a quartz oscillator may be used as a frequency stabiliser for radio purposes.

Quartz plates vibrating longitudinally in the direction of their thickness (the electric axis) have been employed by Langevin, Boyle, and others as a source of suber-sonic vibrations, more particularly for use under water. The same apparatus is used in the converse process of reception, for the alternating pressure of the arriving sound waves produces corresponding electrical effects which, when suitably amplified and heterodyned, can be heard in telephones. Langevin and Boyle have employed this apparatus for the detection by an echo method of submerged objects (wrecks, icebergs, etc.), the sound emitted from a large disc of quartz being sharply directional and therefore suitable for such purposes. (See numerous papers by R. W. Boyle in Proc. Roy. Soc. of Canada 1922—28.) R. W. Wood and A. L. Loomis, using a piezo-electric quartz crystal vibrating at frequencies of the order 5x106 cycles per second have obtained striking effects of a physical and biological nature (Phil. Mag., Sept. 1927). With the crystal vibrating under oil, they estimated the pressure of the sound radiation to be equal to 150 grams weight—the free surface of the oil being raised into a mound 7 cm. high!

The uses of Rochelle salt as a sound generator and receiver have been demonstrated by Nicholson (Amer. Inst. Elect. Eng. Proc., Nov. 1919) who in one application used the crystal to replace a gramophone sound-box, the amplified e.m.f.s produced in the crystal being sufficient to operate loud-speakers or telephones. The elasticity of Rochelle salt is very small,  $E=3\times ro^3$  as compared with  $8\times ro^{11}$  for quartz and  $2\times ro^2$  for steel. (An excellent bibliography on piezo-electricity and its applications is given by W. G. Cady in the Proc. Inst. Radio Engineers, April 1928.)

Torsional Vibrations of Rods.—A solid rod or tube of circular, section may be twisted in such a way that each transverse section remains in its own plane. If the section is not

<sup>1</sup>A. W. Pierce and J. H. Vincent have excited rods of nickel (and alloys of nickel-iron) into resonant vibration by magnetostriction.

circular, a warping is liable to take place and the analysis is very complex. Consider a tube of radius r and thickness  $\delta r$  and let  $\theta$  be the angular displacement of any section distant x from the origin. The "shear" of the material of the tube is  $r \cdot \partial \theta / \partial x$ . The opposing elastic force per unit area is  $\mu r \partial \theta / \partial x$  where  $\mu$  is the coefficient of rigidity of the material  $(\mu = E/x(\sigma + 1)$  in which E is Young's modulus and  $\sigma$  is Poisson's ratio). Since the area of section of the tube is  $2\pi r \delta r$  the moment of this force round the axis is  $2\mu \cdot \pi r^2 \delta r \cdot \partial \theta / \partial x$  and the restoring force acting on the slice of thickness  $\delta x$  has the moment  $2\mu \pi r^2 \delta r \cdot \partial \theta / \partial x^2$ . Now the moment of inertia of the slice is  $2\pi r \delta r \cdot \delta x \cdot \rho r^2$  ( $\rho$  is the density of the material) whence the equation of motion is

$$\rho \frac{\partial^2 \theta}{\partial t^2} = \mu \frac{\partial^2 \theta}{\partial x^2} \quad \text{or} \quad \frac{\partial^2 \theta}{\partial t^2} = c^2 \frac{\partial^2 \theta}{\partial x^2} \quad \text{where} \quad c = \sqrt{\frac{\mu}{\rho}} \quad (24)$$

which is independent of r, and therefore equally applicable to tubes of all radii and to a solid rod. The velocity of tersional vauve transmission is  $c = \sqrt{(\mu/\rho)}$ . The ratio of this velocity to the corresponding longitudinal velocity is  $\sqrt{(\mu/E)} = 1:\sqrt{(2(\sigma+1)]}$ . Taking  $\sigma = 0.25$  for a steel rod the ratio of velocities becomes 1.58. The possible frequencies of torsional vibration of a rod will be

$$N = \frac{s}{2l} \sqrt{\frac{\mu}{\rho}} \tag{25}$$

analogous to the harmonic series for the longitudinal vibrations. Torsional vibrations are readily set up by applying tangential forces of a fricţional character, e.g., by means of a resined cloth, to the free end of a rod clamped at a suitable point.

Vibrations of Membranes.—The transverse vibrations of stretched membranes are related to those of diaphragms and plates in a manner analogous to the transverse vibrations of stretched strings and elastic bars. In the former case the vibrations are conditioned by the applied tension and are independent of elastic forces, whereas in the latter the elastic forces are all-important and tension almost negligible.

By analogy with the case of wave motion in one dimension (a stretched string) it may be shown that the equation

$$m\frac{\partial^2 \xi}{\partial \ell^2} = T\left(\frac{\partial^2 \xi}{\partial x^2} + \frac{\partial^2 \xi}{\partial y^2}\right) \tag{26}$$

represents the motion of a stretched, two-dimensional-membrane where T is the tension m the mass per unit area  $(\rho \times \text{thickness})$  and  $\xi$  the transverse displacement at a point xy. The velocity of wave motion is  $c = \sqrt{(T/m)}$  as in the case of strings. The complete mathematical analysis for stretched membranes of various shapes is given in Rayleigh and Lamb's treatises on Sound. In the case of a circular membrane of radius a the fundamental frequency is shown to be

$$N = \frac{0.765}{2a} \sqrt{\frac{T}{m}}.$$
 (26a)

In the higher partials the diaphragm becomes divided into nodal rings and diameters.

Membranes approximating to the ideal type have been made from soap films, or films of thin collodion, stretched on a metal ring, the vibrations of such thin films being examined by optical methods. Sheets of parchment or of thin metal (steel) are more suitable when it is required to examine the effects of tension. Wente's condenser microphone (see fig. 16a) (see MICROPHONE) has a highly tensioned steel membrane of fundamental frequency about 10,000 cycles per second. The various modes of vibration of a steel membrane are conveniently studied by means of a small electro-magnet (the magnet system of any ordinary telephone receiver will serve the purpose) and a valve oscillator with a suitable range of frequency-control. As a rule, the agreement between theory and observation is only approximate, for the theory generally given takes no account of the serious damping and loading of the diaphragm due to the medium (air) in contact with it. The stiffness of the membrane is not always negligible as assumed in the theory. Examples of membranes as sources of sound are to be found in various forms of drums, tamborines, etc. In the drum, the vibrations of the membrane are reinforced by the vibrations of an air cavity in resonance with it.

Vibration of Diaphragms.—When elastic restoring forces are called into play and tension is of secondary importance we come to the case of the diaphragm. Rayleigh has calculated the periods and motions in vacuo, of a thin circular elastic plate rigidly clamped at the edge. By means of a complex analysis he found that the fundamental frequency of vibration is given by

$$N = \frac{2 \cdot 96}{2\pi} \cdot \frac{h}{a^2} \sqrt{\frac{E}{\rho(1 - \sigma^2)}}$$
 (27)

where h is the thickness and a the radius of the diaphragm, E Young's modulus,  $\rho$  the density and  $\sigma$  Poisson's ratio for the material. More recently, Lamb (Roy, Soc, Proc, A, Vol, 98, 1020) has calculated the frequency and damping of circular diaphragms in air and in water, the value of the frequency in air agreeing closely with Rayleigh's estimate. Thus for a steel diaphragm  $E = 2 \times 10^{18}$ ,  $\rho = 7.8$ ,  $\sigma = 0.28$ , whence  $c = \sqrt{(E/\rho(1-\sigma^2)]} = 5.27 \times 10^5$  cms,/sec., and  $N = 2.5 \times 10^5$  .  $h/a^2$  cycles per second. If h = 0.1 cm, and a = 5 cms, N will be 1,000 cycles per second in air. The addition of a load m to the centre of a diaphragm of mass M has the effect of lowering the frequency given by (27) in the ratio  $1/\sqrt{(1+Sym}/M)$ .

Diaphragm Vibrating in Contact with Water or Other Medium .-The presence of an extensive medium, say water, in contact with the diaphragm has two effects, (1) the frequency is lowered on account of the loading due to the added mass of water vibrating with the diaphragm, and (2) the vibrations are damped owing to the energy radiated as sound waves into the water. Lamb has shown in the case of a diaphragm with one side only in water, that the inertia of the diaphragm is increased in the ratio  $(1+\beta)$  where  $\beta = 0.6689 \rho_1 a/\rho h$  ( $\rho_1$  being the density of the water,  $\rho$  the density of the material of the diaphragm, a the radius and h the thickness). The frequency given by (27) must therefore be divided by  $\sqrt{(1+\beta)}$  in this case. When both sides of the diaphragm are immersed the value of  $\beta$  must be doubled. The persistence of the vibrations is given by  $N/k = 0.385(1+\beta)^{3/2}\rho c_1/\rho_1 c$ , where  $c_1$ is the velocity of sound in the medium and c in the material of the diaphragm. Thus, in the above example where the frequency, is modified by the water, is about 550, the range over which the energy will exceed half the maximum (indicating sharpness of resonance, see page 8) lies between 530 and 570 p.p.s. The persistence is increased, and the resonance is sharpened, the thinner the diaphragm and the greater the load.

Diaphragms form one of the most convenient means of producing and receiving sounds in air or in water. Numerous forms of diaphragm telephone receivers and microphone transmitters are in daily use. Large diaphragms are used as sources of sound-power for signalling over large distances in air or under water. A diaphragm operated at resonance by electro-magnetic methods may become an efficient generator of sound. By suitably choosing its dimensions the frequency of the sound may have any value up to the limits of audibility. A thick diaphragm of small diameter excited by an electro-magnet provides a very convenient source of high frequency sound as an alternative to a bird call, etc., in experimental work.

Directional property of Membranes and Diaphragms.—If a membrane or a diaphragm be mounted on an annular ring it will possess definite directional properties used either as a transmitter or receiver of sound. Regarding it as a transmitter, the sound emitted from opposite sides will be of the same intensity but in exactly opposite phase. Consequently an observer "edge-on" to the diaphragm will hear nothing at all, for the sounds proceeding from opposite sides of the disc will exactly neutralize each other. In the "broadside-on" position, however, the sound from the back of the diaphragm will be partially screened by the annular ring and by the diaphragm itself, whereas the sound from the front will reach the observer unobstructed. As the transmitter is rotated through 36° therefore, the observer will hear two distinct maxima, 18° apart, separated by two corresponding minima, or zero positions. The maxima will, of course, be of

smaller intensity than that observed with one side of the diaphragm completely screened (in which case it is non-directional). The directional properties of an unscreened diaphragm may be simply demonstrated as a receiver of sound by means of a "button" granular microphone attached at the centre. The microphone gives maximum and zero response in the "broadside-on" and "edge-on" positions respectively, relative to a fixed source of sound.

Vibration of Plates .-- We have already referred to the case of a quartz plate vibrating with equal amplitude and phase over its whole surface, this being treated as a special example of longitudinal vibration. We have also dealt with a circular plate clamped at the edge (i.e., a circular diaphragm), the frequency of the fundamental being  $0.47hc/a^2$ , and the overtones  $1.006hc/a^2$  and  $1.827hc/a^2$  for one nodal diameter and one nodal circle respectively. When the plate is free at the edge the mathematical treatment becomes very complex. Near the edge, a peculiar state of strain exists sometimes resulting in abnormally large shearing forces on sections perpendicular to the edge. experimental study of the vibrations of such plates, free at the edge and clamped at the centre of symmetry, begins with Chladni (1787). The method of producing Chladni's figures by bowing and touching certain points on the edge of the plate covered with fine sand, is well known. The nodal figures are very striking in their appearance and wonderful variety-nothing further is needed to testify to the complexity of the problem. Chladni preferred to use glass plates, as their transparency permits of the fingers being used to damp points underneath which are shown to be nodal by the sand above. Simple figures correspond to low frequency tones, and the more complicated figures to the higher tones. Chladni obtained 52 different figures with a square plate and 43 with a circular plate. Metal plates of moderate thickness when struck with a hammer are sometimes used as gongs. The Submarine Signalling Company have used such a gong under the sea, describing it as a "disc-bell" for life-

Curved Plates, Cylinders and Bells.—The complex problem of the flat plate is still further complicated when the plate is curved—for it becomes increasingly difficult to separate the various possible modes of vibration. Rayleigh has calculated the fundamental frequency N of vibration of a thin cylindrical

shell, obtaining  $N \approx \frac{k}{a^2} \left| \frac{e}{\rho} \right|$  where e is an elastic modulus involving bulk modulus and  $\rho$  the density of the cylinder.

A bell may be regarded as a progressive development of a curved plate or, in certain forms, it may be treated as a cylindrical shell with one end closed. The possible variety of forms is far too numerous even to mention here. In practically all cases the bell is supported at the centre of symmetry and is excited by striking near the free edge. Rayleigh made a particular study of the vibrations of church bells, and distinguished five characteristic tones: Lowest tone (4 nodal meridians, no nodal circle), second tone (4 nodal meridians, one nodal circle), third tone (6 nodal meridians, sound best produced when the clapper strikes the bell on the lower thick part termed the "sound bow"), fourth tone (6 nodal meridians, best elicited by striking half way up), fifth and highest tone (8 nodal meridians). Bell founders in England recognise five chief tones in a church bell, reckoning from the highest they are termed the "nominal," "fifth," "tierce," "fundamental," and "hum-note." By suitable distribution of metal in the bell the founder aims at making the hum-note, fundamental and nominal successive octaves-but seldom succeeds. Massive bronze bells are used in charted positions, e.g., lightships and buoys, under the sea as a means of signalling to ships suitably fitted with hydrophones (underwater microphenes) to receive the sound. Sound travels for long distances under water and these bells can be heard many miles away, if the conditions are favourable.

Vibrations of Air Cavities.—Columns of Air: Organ pipes. The simplest case of a vibrating mass of air in a solid enclosure is that of a parallel cylindrical pipe the ends of which may be closed or open. The vibrations of such a column are analogous to the longitudinal vibrations of a solid rod. Provided the diameter of the pipe is not too small, so that viscous drag at the boundary is unimportant, and not too great compared with the length of the pipe and the wave length of the sound, we can assume at any instant, the motion of particles in any particular cross section to be the same. That is, we are dealing with plane waves of sound in the pipe. As in the case of transverse vibrations of strings and longitudinal vibrations of rods, stationary waves are produced in the air column due to the combined effects of the direct and end-reflected waves. Thus the equation of wave motion in the pipe is  $\partial^2 \xi / \partial t^2 = E/\rho \cdot \partial^2 \xi / \partial x^2$ , indicating a wave travelling with a velocity  $\sqrt{(E/\rho)}$  where E and  $\rho$  are the appropriate values of adiabatic elasticity and density of the gas contained in the pipe. Assuming a simple harmonic wave  $\xi = a \cos nt$ the solution becomes  $\xi = [A \cos(nx/c) + B \sin(nx/c)] \cos nt$ . With the appropriate end conditions  $\xi = 0$  at a node (a solid end) and  $\partial \xi/\partial x = 0$  at an antinode (an open end) the various modes of vibration are readily determined.

Remembering that a pulse of compression is reflected as a rarefaction at an open end and as a compression at a closed end, it will be evident that a wave must travel twice the length of a pipe open at both ends, and four times the length of a pipe closed at one end, before the wave repeats itself, i.e., in one period. If  $\lambda$  is the wave length and N the frequency in the stationary wave then  $N = c/\lambda$ . For a pipe open at both ends each open end must be an antinode and the length of the pipe a multiple of  $\lambda/2$ , that is,  $l = s\lambda/2$  where s = r, 2, 3, etc. We have in this case therefore a complete harmonic series of partials whose frequencies are

given by  $N = \frac{sl}{2l}\sqrt{\frac{E}{\rho}}$ , the corresponding wave lengths being proportional to 1, 1/2, 1/3, 1/4, etc.

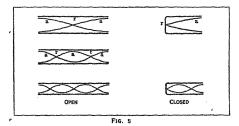

For a pipe closed at one end the closed end must be a node and the length of the pipe an odd mulliple of  $\lambda/4$ , that is  $l=s\lambda/4$  where s=1, 3, 5, etc. The partials therefore form an odd harmonic series the frequencies being  $N=\frac{s}{4t}\sqrt{\frac{E}{\rho}}$  where s is an

odd integer. The corresponding wave lengths are proportional to 1, 1/3, 1/5, etc. A closed pipe resonates to the same fundamental frequency, as an open pipe of twice the length.

frequency as an open pipe of twice the length. The position of the nodes n and antinodes a for a few of the partials of "open" and "closed" pipes are indicated in fig. 5.

partials of "open" and "closed" pipes are indicated in fig. 5.

Correction at Open End.—The approximate theory indicated above (due to Bernouilli) assumes an antinode at the open end.

A true antinode is a point of zero pressure-variation and maximum displacement-amplitude. At the open end of a tube the stationary plane waves inside are changing to spherical progressive waves outside. In other words, the tube radiates sound energy in all directions from the end of the tube. On account of this radiation, the intensity of the reflected waves from the open end is somewhat less than that of the incident waves, which explains the rapid damping of the vibrations when the forcing ceases. The body of air at the open ged has the effect of adding inertia to the air in the tube. Consequently there is a virtual increase

in the length of the air column with a corresponding lowering of pttch. Lord Rayleigh has shown that this effective increase of length approximates to 0.6 times the radius r of the tube if the latter is unlianged. This correction applies at each open end, and is therefore  $1\cdot 2r$  for an open tube, and 0·6r for a closed one It should be observed also, as in the case of rods, that the simple theory only applies when the diameter of the tube is small relative to the length of a loop  $\lambda/2$ 

Resonating Liquids in Metal Tubes.—Columns of liquid enclosed in metal tubes may also be set into resonant vibration. On account of the yielding of the walls of the tube, however, the velocity  $\sqrt{(E/\rho)}$  of the wave is slightly modified since the coefficient of elasticity involved is dependent on the extent of such yielding. The subject has been examined theoretically by Hr Lamb (Sound, p. 174) and by Green (Phil. Mag., 45, May 1923), who has also determined experimentally the change of velocity produced in various liquids by this yielding

Organ P<sub>i</sub>pes.—One of the most important applications of the vibration of air columns is found in the organ pipe. This usually takes the form of a cylindrical metal tube or a wooden pipe of square section. One end of the tube is specially constructed so that a suitable blast of air will set up resonant vibrations in the column of air. In the open "fine" organ pipe the blast of air impinges on a thin lip which forms the upper edge of a narrow slit opening into the tube. When the blast is correctly adjusted the pipe "speaks" and the air column resonates. The fundamental tone is sounded when the blast is moderate, and by increasing the power of the blast the harmonics can successively be produced.

In another form, known as the "reed" pipe, the blast of air impinges on a reed which controls the amount of air entering the pipe. The reed is set in vibration and puffs of air are admitted to the pipe which resonates under the correct conditions. The reed cannot be regarded as a freely vibrating spring for it is affected by the air blast and the resonance in the pipe. "Organ" pipes have been made covering a range of frequencies, from 8 to 16,000 cycles per second, corresponding to lengths of 64 ft. to \frac{1}{2}\$ in respectively. Fifes, flutes, oboes, etc., are other examples of musical instruments employing resonant air columns.

Small Air Cavities:  $\dot{H}$ elmholts Resonators.—The vibrations of air cavities almost completely enclosed were first studied by H. von Helmholtz and have considerable practical importance. A volume of enclosed air having only a small "neck" connecting with the external air radiates very little energy when set into resonant vibration. The damping is therefore very small and the tuning is very exact. The device is therefore very sensitive to a narrow range of frequencies. The motion of the air in the cavity is almost negligible compared with that in the narrow neck. Consequently we may regard the air in the neck as a piston having mass m=plS ( $\rho$  density, l length, and S area of neck), while the air in the cavity functions as a spring of "strength"  $f=ES^2/v$  where E is the elasticity  $(=\gamma p)$  of the gas and v the volume of the cavity. The frequency N of such a mass and spring is  $\sqrt{f/m}/2\pi$ 

activity. The frequency N of such a mass and spring is  $\sqrt[4]{f/m/2\pi}$  i.e.,  $N = \frac{1}{2\pi} \sqrt{\frac{ES^2}{v \cdot \rho l S}}$  or  $\frac{c}{2\pi} \sqrt{\frac{S}{v}}$  since  $c = \sqrt{E/\rho}$ . The ratio S/l is called the "conductivity" of the neck. For a circular aperture in a thin wall, Rayleigh shows that this quantity is equal to the diameter (2a) whence  $2\pi N = c\sqrt{(2a/v)}$ . The frequency is independent of the shape of the cavity provided its linear dimensions are not comparable with a wave length of the sound to which it resonates. A "spherical" Helmholtz resonator is shown in fig. 6. A series of resonators of graduated frequencies (i.e., of varying volume or area of mouth) may be used in the frequency analysis of complex sounds. Resonance may be detected by the ear or by means of a sensitive manometric capsule applied to the small pipe at the base of the resonator, or by means of a Tucker hot-wire microphone (see p. 31) placed in the mouth. Resonators of large volume, and correspondingly low frequency, fitted with hot-wire microphones were employed in the detection and location of gens during World War I. (See Sound-Ranging.) Large resonant microphones are also used in the detection of

Recently, E. G. Richardson (Proc. Phys. Soc., May 1928) by using acoustic impedance methods, has developed a theory of speech about 2,500 ergs/sec. vibration of air cavities which covers the extreme cases of pipes and resonant cavities, and avoids the necessity for a special open-end correction. He obtains the formula  $\tanh L = \kappa/kA$ where  $k = 2\pi N/c$ ,  $\kappa$  is the conductivity of the neck and A is the area of section of the cavity, assumed cylindrical. This formula leads to the recognised values of N for

pipes and resonators. Double Resonators .- In certain circumstances, where an increased sensitivity is desired, double resonators, consisting, for example, of a resonator of the closed pipe variety combined with one of the Helm-

holtz type, are usually employed. By this method, which was first suggested by Boys, a large increase in ampli-

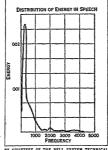

tude may, as a rule, be obtained. The theory of such compound resonators was given by Rayleigh, and has been considerably extended recently by E. T. Paris, who uses them in conjunction with the hot-wire microphone.

Helmholtz Resonator Combined with Tuned Reed -E. E. Fournier d'Albe has employed a sharply tuned reed (clamped free) with a small mirror attached, to indicate resonance in an air cavity. The resonant vibrations in the air cavity agitate the tuned reed, which lies across the mouth, and cause a spot of light, reflected from the mirror, to oscillate. The combination of reed and air cavity responds to one frequency only, for the overtones of the cavity do not correspond to those of the reed.

The Voice and Speech .- The human voice is an excellent example of a combination of vibrating reeds (the vocal cords) and resonant air cavities (the front and back parts of the mouth, separated by the tongue, and the upper or nasal cavity). The analysis and synthesis of speech sounds was commenced by Helmholtz. More recently Paget has shown that "every series of sung or spoken vowels is in fact a trio performed by three instruments, a reed and two resonators-soprano and alto-of which the soprano is in close harmonic relation with the reed." In a series of important papers (Proc. Roy. Soc., 1923, 1924, 1927) Paget has analysed and synthesised the vowel and con-

sonant sounds. Observations on breathed vowel sounds indicated that in every case the oral cavity as a whole, from larynx to lips, actually gives two simultaneous resonances for each vowel sound. In certain cases, more frequent in American "accent" a third resonance due to the upper or nasal cavity may be introduced. By means of plasticine models Paget successfully reproduced the various vowel and more important consonant sounds, as well as combinations of these in well recognised words. Crandall and Mackenzie (Phys. Rev., March 1922) have determined experimentally the energy distribution in speech as a

function of frequency. (See curve fig. 7.) The maximum energy of the male voice occurs at a frequency near 120 p.p.s., the female voice having a maximum about an octave higher. In spite of the fact that the energy of the voice is mostly of low pitch it is the high pitched sounds which are essential to intelligibility of speech. The clearness of speech is unimpaired if all sounds up to 500 frequency are "filtered" out (60% of the sound energy being thereby removed). We shall see later that the ear is most sensitive in the region 1,000 to 4,000 frequency. The rate of emission of sound energy in conversational speech has been estimated by

Sabine (Phys. Rev., 21, 1923) as 125 ergs/sec and for public

Absorption of Sound by Resonators: Sound Filters .-A well tuned resonator absorbs energy of corresponding frequency from the sound-field in which it is placed. This absorption may extend over an area of the order  $\lambda^2/\pi$  where  $\lambda$  is the wave length of the incident sound  $(\lambda = c/N)$ . Quincke (1866) employed resonators to stop tones of definite pitch from reaching the ear (see Rayleigh, Sound, vol. ii., p. 210)—the arrangement acting as a sound-filter. A complex sound passing through a pipe could have any particular tone removed, by fitting a suitable side tube to the pipe. This side tube of length l was closed by a sliding piston which served to "tune" the tube (4l=c/N) to any frequency N it was desired to absorb from the main pipe. Using a succession of such tuned side tubes a corresponding number of tones could be filtered out of the direct sound. G. W. Stewart (Phys. Rev., 1923-26) has greatly extended the possibilities of sound filters by introducing the analogy of electrical filter circuits and the conception of acoustic impedance. On such a basis it is possible to design "acoustic circuits" functioning as "low-pass," "high-pass" and "band-filters" as in the corresponding electrical cases. The "low-pass" filter transmits only those frequencies below a certain limit, the "high-pass" above a certain limit, and the "band-pass" only within a certain range or rafiges. Filters of this nature are used in the laboratory for purifying sounds, e.g., removing harmonics from a complex wave-form to obtain a pure tone; and in connection with speaking devices.

Measurements of Sound Intensity; Using Air Resonators .-The amplitudes at various points in a vibrating air column or cavity may be examined qualitatively by means of small manometric capsules (fitted with tube to a sensitive flame) or by sensitive membranes carrying fine particles or small mirrors. Quantitative results have been obtained by means of a Rayleigh disc which, when inclined at 45° to the axis of a neck of a double resonator, forms a very sensitive detector—the disc tending to set itself at right angles to the vibrating air current in the neck of the resonator (see p. 14.) Alternatively the hot-wire "microphone" (see p. 31) may be used.

Kundt's Dust Figures.-To exhibit the nodes and antinodes in a resonating air column contained in a glass tube, Kundt devised the method of spreading fine powder (lycopodium seed or fine dry cork dust) along the inside of the tube. The dust is immediately thrown into a pattern indicating the positions of nodes and loops along the tube. The experiment is capable of a number of variations yielding valuable data relative to the velocity of sound in gases and solid rods. The wave length  $\lambda_g$  in the gas contained in the tube is at once obtained from twice the nodal separation—the wave length λ<sub>0</sub> in the rod which excites the vibrations in the air column being, for the fundamental longitudinal vibration, equal to twice the length of the rod. These values give at once the relative velocities in the gas and the rod. (See p. 21.)

Sirens.-The sources of sound to which we have hitherto referred are dependent on the principle of resonance for their efficient action. We shall now deal briefly with an entirely different type of sound generator. In the earliest form of siren a revolving disc perforated with a ring of equally spaced holes interrupted a jet of air from the nozzle of a tube mounted opposite the ring of holes. The fundamental frequency of the note produced by the successive puffs of air emerging beyond the disc is clearly equal to the product of the number of holes and the revolutions per second of the disc. This primitive form is known as Seebeck's Siren (1805-1849). In later forms of siren (C. de la Tour's form) the holes were drilled obliquely to the surface of the disc so that the blast of air also produced the necessary rotation of the disc. In this form the intensity of the note increased with frequency—the sound amplitude being roughly proportional to the pressure of the air supply. In recent laboratory forms the siren is motor driven, means being provided for indicating the speed of the revolving disc and consequently the frequency of the sound. A motor driven siren forms a very

convenient means of determining, by a direct method, the pitch of a note. With a circular nozale and equal circular holes the siren note is generally impure—containing a plentiful supply of harmonics in addition to the fundamental. Milne and Fowler [Roy. Soc., 98, 414, 1921) describe a special form of siren which gives comparatively pure tones. The holes in the rotating disc are specially shaped so that the uncovered area of the nozzle varies sinusoidally.

Dove and Helmholtz produced sirens having several rings of hobes provided with corresponding nozzles, so that one or more tones could be produced simultaneously. Sirens driven by compressed air or steam are in common use as sources of sound. Similar devices modified to suit the special conditions have been used for signalling under water—the air supply of the ordinary siren being replaced in this case by a jet of water which causes rotation of the disc and gives the necessary vibratory impulses to the surrounding water.

The Diaphone, a powerful long range signalling device for use in air, is essentially a siren of the same group as those of Seebeck and La Tour since it differs from them only in the fact that the opening and closing of the ports is effected by a reciprocating instead of a rotary motion—this reciprocation being produced directly by means of the compressed air supply.

The Centrifugal Siren.—This device consists of a radially-vaned cylindrical rotor revolving in a stationary casing in which ports are cut. The vanes are connected in pairs at their outer edges by cylindrical segments, so that rotation causes opening and closing of the fixed ports. Air is drawn through an axial aperture where the vanes are cut away. The sound is produced by the expulsion of air through the ports by the centrifugal action of the rotor which may be driven by an electric motor or internal combustion engine. Sirens of this type constitute very powerful and efficient sources of sound for long distance transmission in air, e.g. for use on light-vessels or shore stations as a means of signalling to ships at night or in foggy weather.

Sounds Produced by Rotating Propellers.-The hum of an etectric fan which increases in pitch with increase of speed can be heard only at a short distance. The noise produced by the propeller (airscrew) of an aeroplane may, under favourable conditions, be heard several miles away. The sound emitted in both these cases arises, in the absence of excessive vibration, from the rotation of the "source and sink system" associated with the pressure differences on the rotating blades. A. Fage (Roy. Soc. Proc., 107, 1925) has analysed the sounds emitted from various types of airscrews by means of a resonator, of continuously variable tuning, fitted with a Tucker hot wire microphone. He found that the sound of rotation consists of a large number of harmonics having as fundamental a note of frequency equal to the product of the number of blades and the rotational speed. In addition to these sounds, "tearing sounds" associated with the shedding of eddies from the blades were also observed but the frequencies were not determined. Sounds arising from the flexural vibrations of the airscrew blades and the shaft were found to have frequencies in agreement with calculation.

Propellers Under Water.—Most of the under-water noise from a moving ship comes from the screw propeller. As it revolves, "cavitations" are formed just behind the blades. When these cavitations collapse either on themselves or on the blades, a noise is produced. This noise has no predominant frequency, although it is to some extent characterised by the beat of the engines or the rush of the turbines which drive the propeller. If the latter revolves slowly the cavitations are not formed and there is very little noise. With suitable receivers (hydrophones) the noise of a ship proceeding at a moderate speed, say 10 or 15 knots, can be heard several miles away. (See Bragg, World of Sound.)

Explosive Sounds.—The ejection of a shell from a gun and the subsequent explosion of the shell are both accompanied by a supply tube. The vibrations pressure-wave of large amplitude which can be detected at long ranges. This pressure-wave has, however, a different character in the two cases—the explosion at the gun is due to the ignition of p. 224, should be consulted.

cordite which burns relatively slowly when compared with the rate of detonation of the T N.T. in the shell. Consequently the gun-wave has a wave-front which is much less abrupt than that of the shell detonation. This appears to the ear as the difference between a "boom" and a "crack." An observer of such pressure waves at a distant point receives what appears to be a continuous train of waves, t.e., a reverberation effect, due to the numerous reflected pulses from objects along the track of the primary pulse. Such reverberations may last several seconds. Similar effects are observed under water on the explosion of a mine or a depth charge. The explosion of a few ounces of guncotton under water can be detected and recorded 30 or 40 miles away. A rapid succession of explosions at equal intervals of time may result in a noise of a more or less musical character. This is exemplified in high speed gas or petrol engines, particularly those with several cylinders operating in succession. The note is harsh and the fundamental is accompanied by a long train of harmonics. The musical noise of a high frequency Wehnelt electrolytic interrupter (used in X-ray work) is also due to a regular succession of explosive impulses, arising from the sudden generation of gas under the liquid. The wave-form of such a series of impulses recorded on a cathode-ray oscillograph indicates the extremely abrupt nature of detonations. A single impulse is often sufficient to set a resonator into vibration, thereby producing, indirectly, a musical note.

A single impulse of an explosive nature, produced by a powerful electric spark has been employed in the study of the progress of a sound-wave under controlled conditions—particularly in connection with the complex reflections of sound-waves in auditoriums. (See Acoustics of Buildings.)

Sounds Maintained by Heat.—Most bodies on being heated will expand and in so doing perform a certain amount of mechanical work. If the phases of the forces thus called into play are favourable, a vibration may be set up and maintained.

Trevelyan's rocker is a good example of such a maintained vibration. It consists of a prism of brass or copper almost triangular in section with one edge grooved to form two adjacent parallel ridges. The prism rests with its groove downwards on a block of lead with a rounded top, the end of the prism terminating in a ball which rests on a smooth surface. When the prism is heated and placed on the lead block it begins to vibrate, the weight being carried alternately on one or the other of the two ridges. The cause of these vibrations was ascribed by Leslie to the expansion of the cold block at the point of contact with the hot metal. The effect can be obtained also by a local heating of the points of contact by means of an electric current.

Singing Flames.-Under certain circumstances a small gas flame inserted into a resonant chamber of air or other gas, will emit a musical sound. If heat be given to the air in a vibrating column at the instant of greatest condensation the vibration will be encouraged. If the phase of the heat supply be reversed the vibration will be discouraged. An essential feature of the maintenance of the vibration is the presence of stationary waves in the gas supply tube as well as in the singing tube. The jet must be a node to correspond with a node in the singing tube where the maximum pressure-amplitude occurs. For most satisfactory operation therefore it is necessary (a) that the gas jet should be at or near a node in the singing tube and (b) that the length of the gas supply tube should be an odd multiple of  $\lambda/4$ (where  $\lambda$  is the wave-length, in the gas, of the note sounded). The tube will not sing at all if the length of the supply tube lies between  $\lambda/4$  and  $\lambda/2$ ,  $3\lambda/4$  and  $\lambda$ , and so on. Spherical resonators, large globes, may also be employed, and bulbous chimneys as used for paraffin lamps give satisfactory results. The intermittent character of a singing flame is easily demonstrated by means of a revolving mirror, from which it appears that at one phase the flame may withdraw itself entirely within the gas supply tube. The vibrations sometimes reach sufficient intensity to extinguish the flame completely. For a complete discussion of the phenomena of singing flames Rayleigh's Sound, vol. ii.,

Gauze Tones.—Rijke in 1859 made the discovery that a sound . of considerable power may be produced by a heated piece of fine metal gauze stretched across the lower part of a vertical open tube containing air. In the earlier experiments the gauze was heated by a gas flame and the sound was observed immediately after the removal of the flame. Keeping the gauze hot by means of an electric current the sound may be maintained indefinitely. The maintenance depends on the variable transfer of heat due to the motion of air through the gauze, this motion being a uniform upward convection current with a superposed alternating motion due to the resonant vibration of the air in the tube. In the lower half of the tube the alternating flow assists the direct flow a quarter period before the phase of greatest condensation and opposes it a quarter period after this phase. Bosscha and Reiss (1859) demonstrated the complementary phenomenon. current of hot air fall on a cold gauze, sound is produced-in this case the phase relationship requires the gauze to be in the upper half of the tube, preferably about a quarter the length of the tube from the top.

The Thermophone. Fine Wires or Strips Heated by Alternating Currents. - When an alternating current i sinnt is passed through a fine wire of resistance R the heat developed is proportional to  $Ri^2\sin^2nt = \frac{1}{2}Ri^2(1-\cos 2nt)$ . Consequently the heat developed will vary between 0 and  $\frac{1}{2}Ri^2$  at a frequency  $2n/2\pi$ , that is, at twice the frequency of the current. If a sufficiently large initial direct current io be passed through the wire the double frequency term in  $R(i_0+i\sin nt)^2$  or  $\{R(i_0^2+\frac{1}{2}i^2)+2Ri_0i\sin nt-\frac{1}{2}Ri^2\cos 2nt\}$ may be made negligible—the fluctuations of heating effect then vary with the frequency  $n/2\pi$  of the current.

Using very fine platinum wires (10-4cm. thick), P. de Lange (Roy. Soc. Proc., 91, Ap. 1, 1915) demonstrated that the decrease and increase of heat took place synchronously with the A.C. supply. The air surrounding the wire was thereby rapidly heated and cooled, the corresponding expansions and contractions appearing as sound. Ordinary telephonic currents, of speech frequency, were shown to be sufficient to produce easily audible sounds in a small earpiece containing the fine wire heater and a small volume of air. This device is known as a Thermothone. The reproduction is of good quality, but somewhat feeble relative to the response of electro-magnet telephone receivers. Provided the frequency is not too high, the thermophone has a possible application as a metrical source of sound.

Directional Sources of Sound.—It is evident that a greater range of transmission will result if a given amount of sound energy is confined to a cone with a small angle of divergence instead of spreading uniformly in all directions. Other advantages of a directional transmitter will be equally apparent. Certain sources of sound exhibit inherent "directional" properties, due to properties, due to the fact that their dimensions are considerably greater than a wave length of the sound they emit. Other sources may show no inherent directional property but may be made directional by the use of some attachment such as a trumpet or a mirror. A line or an area of equally spaced non-directional sources vibrating

in phase may act as a directional compound source.

Sources of Large Area.—The linear dimensions not small com-pared with a wave-length. Rayleigh (vol. ii., p. 138) refers to the directional properties of a speaking trumpet when used to transmit high pitched sounds, such as a whisper or a hiss. An instructive example of this nature is the case of radiation of high frequency sound waves from one face of a quartz piezo-electric piston" oscillating with uniform amplitude and phase at all points of its surface (see R. W. Boyle, Proc. Roy. Soc. Canada, III, 1925, p. 167). The sound-distribution round such a source is analogous to that of plane waves of monochromatic light falling on an aperture and forming a diffraction pattern beyond. Consider the case of a circular piston source of radius a radiating waves of length  $\lambda$  ( $\lambda = c/N$  where c is the velocity of sound in the medium and N the frequency of vibration). As in the optical case, the sound is a maximum along the axis of the piston where all the elementary disturbances from the various points of the piston arrive in the same phase. In directions inclined to the

axis the intensity is less, diminishing steadily to a minimum when the difference in distance to the nearest and the furthest points of the piston is rather more than half a wave-length. «In this case, the effect of the further portion of the disc is just neutralised by the effect of the nearer portion. In directions still more inclined, the sound increases again to an intensity equal to 0.017 of that along the axis. This is succeeded by another minimum value and further maxima of small intensity-corresponding to the various diffraction rings in the optical analogue. angle  $\alpha$  at which the first silence occurs is  $\sin^{-1}(0.610\lambda/R)$ . Thus the central "beam" of sound will be confined to a cone of small angle when the radius R of the piston is many times the wave-length. The polar distribution of amplitude is somewhat similar to that shown in figure 8 for a line of small nondirectional sources. When the radius R does not exceed  $\lambda/4$  the elementary disturbances from the piston combine without much opposition in phase, and the intensity is nearly the same in all directions—the case of a nondirectional source of sound.

Rayleigh obtained general verification of this theory by means of a speaking trumpet and high pitched sounds-a considerable concentration of sound on the axis being obtained. Boyle, using a Langevin type of piezo-electric quartz disc (see p. 12) showed that the sound distribution (the polar diagram) in water was in good agreement with theory. In one example  $R=7.65^{\circ}\text{cm}$ , N=135.000 p.p.sec.,  $c=1.5\times10^{\circ}$  cm./sec. for water,  $\lambda=1.11$  cms. whence  $\alpha=5^{\circ}$  approximately. This angle was verified experimentally. The application of such a high frequency directional sound beam has already been mentioned.

Double Sources .- The "piston" radiator to which we have referred is a single source of sound—it radiates from one face only, the anterior face being suitably screened. A vibrating diaphragm mounted on a ring radiates from both faces, the radiation from one face being at any instant in opposite phase to that from the other face. Such a vibrator is described as a double source. As we have seen (see p. 13) a double source, such as a diaphragm on a ring, situated in an open space, air or water, is inaudible from any point in its equatorial plane, maximum sound being

received at right angles to this plane.

Nondirectional Source Used with Mirrors, Trumpets, Zone Plates, etc.-As in the case of piston sources of large area, a "directed" source, employing for example a mirror or a trumpet, can exhibit good directional properties only if the dimensions of the mirror, etc., are not small compared with the wave-length of the sound. This condition involves bulky apparatus if the wavelength is appreciable, the alternative being the use of high frequency sounds of short wave-length. If the beam is to be narrow, it is also desirable that the area of the source at the focus of a mirror for example should not be large. This involves a further difficulty when a large sound-output is required, for the source must then have a very large amplitude, a condition which leads to inefficient transmission both in air and in water. In air serious degradation of energy may take place at large amplitudes (see Hart, Roy. Soc. Proc., A. 105, 1924, p. 80) and in water "cavitation" troubles arise (see Boyle, Roy. Soc. Proc., Canada, 111, 1922, p. 157). The use of mirrors, trumpets, zone plates, etc., are consequently more suited to the directional reception of high frequency sounds-where such troubles do not arise. Concave mirrors of say 1 to 2 feet diameter and 6 to 12 inches focal length are fairly efficient reflectors of high pitched sounds like a watch tick or the notes from a Galton's whistle.

Multiple Sources .- As in the case of a large piston vibrator, a line of small "point," sources, suitably arranged, will have definite directional properties. Suppose we have "m" equidistant sources in a straight line vibrating with the same phase, amplitude, and frequency. We require to know the polar distribution of amplitude in any plane passing through the line of m sources. (See fig. 8a.) It is readily proved that the resultant amplitude r at a distant point P is given by

$$r = \frac{\sin(m\pi d/\lambda \cdot \cos\alpha)}{m\sin(\pi d/\lambda \cdot \cos\alpha)}$$

if d is the spacing-distance of the sources each of amplitude 1/m, and  $\alpha$  is the orientation of the point P with respect to the line source. An important case arises when  $d=\lambda/2$ , i.e., when the sources are spaced half a wave-length apart. Then

$$r = \sin(\pi/2 \cdot m\cos\alpha)/m\sin(\frac{\pi}{2} \cdot \cos\alpha)$$
.

This is zero whenever  $\sin (\pi/2 \cdot m \cos \alpha)$  is zero, i.e., whenever  $\cos\alpha \cdot m/2$  is an integer. Suppose, for example there are 6 sources spaced  $\lambda/2$  apart, then  $m \cos \alpha/2$  may be 1, 2, or 3, whence  $\alpha = 70^{\circ} 48'$ ,  $48^{\circ} 42'$  and  $0^{\circ}$  giving the directions OP of zero amplitude. The primary maximum occurs when  $\alpha = 90^{\circ}$  and secondary maxima at  $\alpha = 60^{\circ}$  and  $30^{\circ}$  approx. The polar distribution from o to  $\pi$  is shown in fig. 8b the value of r being plotted radially from O in the direction  $\alpha$ . This distribution is the same in all planes which include the line of sources. When d has other values, the polar distribution includes secondary maxima which may approach the primary in magnitude (see paper by H. Stenzel, Elecktrische Nachrichten Technik, Band 4, Heft 6, 1927, pp. 239–253). It will be seen that a vertical line of sources spaced  $\lambda/2$ apart will give a definite concentration of energy in a horizontal plane at right angles to the line of sources. Such a concentration is, for example, of considerable importance in a fog signalling device, where a maximum energy concentration is required in a horizontal plane surrounding a light-vessel. It may similarly be shown that a number of equidistant sources arranged on a circle and vibrating in phase will give a primary maximum of intensity on the axis, with a number of zero and secondary maxima positions as in the case of a disc.

Aeolian Tones .- The "singing" of telegraph wires and the "whistling" of the wind through tall grass and trees are very familiar sounds. The "thrumming" of a tightly stretched wire in a stream of water is evidently due to a similar cause. Aeolian tones are produced when wind rushes past a stretched wire, their excitation depending on the formation of unstable vortex sheets. When wind of sufficient velocity passes a wire, a double series of vortices are set up immediately behind it, one set revolving in the opposite direction to the other and the flow of air past the wire wavers from side to side. In this manner vibrations are set up in the surrounding air which, under the right conditions, will be audible. Strouhal investigated the effect by revolving a vertical stretched wire about a parallel axis. He found that the frequency was expressed by  $N=0.185 \ v/d$  where v is the velocity and d the diameter of the wire. When the speed is such that N corresponds with one of the natural frequencies of the wire the sound is greatly increased. Rayleigh showed that the vibrations of the wire are transverse to the direction of the wind. This is readily explained on the vortex theory; the oscillations of air flow behind the wire reacting on the wire itself. The Aeolian harp consists of a number of wires, all of the same low pitch but of different thicknesses stretched on a sounding-board and exposed to the wind. The varying thicknesses of the strings results in a series of different notes.

Noises in General.—In addition to the various sources of sound to which we have referred there are innumerable others. Almost every material object in motion is a source of sound vibration. In all parts of the world there has been a steady increase in traffic noise during recent years, the problem of the reduction of such noise becoming increasingly acute. Relative motion and intermittent contact between solid bodies, such as a vehicle on a road, results in a shock excitation of the numerous resonant vibrations which are possible in a complex structure. A heavy vehicle fitted with solid tyres and having many loose parts is an irritating example of this when it runs over a somewhat irregular road surface. The complex noise issuing from such a vehicle may be analysed into the simpler forms which we have considered above. The prevention of such noises involves many considerations, but obvious improvements may be obtained by (1) use of pneumatic tyres, (2) tightening of all loose "rattling" contacts, (3) balancing of all parts of machinery in rapid motion, (4) use of oil to reduce frictional noises, (5) use of

pressure reducers or "silencers" for exhaust gases, etc.

The noise of breaking waves or rushing water may be ascribed to the resonant vibrations of air cavities enclosed momentarily by the water.

#### TRANSMISSION OF SOUND

It is important now to consider what takes place in an extended elastic medium (solid, liquid or gas) containing a source of sound. Sound waves are the inevitable result when vibratory stresses are set up by any means at any point of an elastic medium. Such sound waves consist of alternations of condensation and rarefaction, corresponding to the successive forward and backward movements of the source. The state of compression is passed on from layer to layer of the medium, with the velocity of sound; this being followed in turn by a rarefaction, another compression, and so on, as long as the source continues to vibrate. The phenomena of propagation of such waves of condensation and rarefaction may be demonstrated very simply by means of a long helical spring supported at suitable intervals by thin threads. Simple harmonic longitudinal displacement of one end of such a spring results in the generation of waves which travel along the spring at a definite speed. In such waves, as in sound-waves, the displacements of individual particles are in the direction of propagation of the wave-the motion is consequently termed longitudinal, as distinct from transverse wave motion in which the displacements are at right angles to the direction in which the wave travels (e.g., ripples on water, or waves travelling along a stretched string). If the condensational wave travels with a uniform velocity c cms./sec and the source of sound has a frequency of N periods per second, it will be clear, without formal proof, that there are N condensation and N rarefactions in the distance c covered by the wave in one second. Now the distance, by which one condensation is ahead of the next, is called the wave-length \( \lambda \) of the sound in the medium; consequently we have  $N\lambda = c$ . When a simple harmonic vibration is transmitted through the medium the linear density of the particles, or their state of compression or expansion, is at any instant represented by a simple harmonic curve which repeats itself at regular intervals of a wave-length.

Plane Waves.—The problem in its simplest form is that of transmission of a plane (or non-spreading) simple harmonic wave in a positive direction along the axis of x. The particle displacement  $\xi$  at any time t of a point whose mean position is x will be given by

$$\xi = a \sin_2 \pi (t/\tau - x/\lambda) \tag{1}$$

$$\xi = a \sin_2 \pi (Nt - x/\lambda) \tag{2}$$

where a is the amplitude,  $\tau$  and N the period and frequency and  $\lambda$  the wave-length of the vibration. Writing  $c=N\lambda=\lambda/\tau$  we obtain other forms of these equations, viz.,

$$\xi = a \sin[2\pi/\lambda \cdot (ct - x)] \tag{3}$$

and 
$$\xi = a \sin n(t - x/c)$$
 (4)

where n has the usual significance and is equal to  $2\pi N$ . These four alternative expressions for the particle displacement  $\xi$  in a progressive plane wave are convenient for most purposes. Comparison of these relations shows that the phases, in the case of progressive waves, may be expressed in terms of fractions of a wave length  $\lambda$  which corresponds to a phase-angle of  $2\pi$ . Thus the difference of phase between the vibrations of two particles at  $x_1$  and  $x_2$  respectively from the origin will be  $2\pi \left(x_2-x_1\right)/\lambda$ . It will be evident that a system of waves travelling in the negative direction of x will be represented by the introduction of a positive instead of a negative sign inside the brackets in the above expressions for  $\xi$ . A system of simple harmonic progressive waves may, of course, be represented graphically with the displacement  $\xi$  plotted as ordinates and the time t as abscissae.

Velocity and Acceleration of Particles in the Wave.—Differentiating  $\xi$  with respect to t we obtain the particle velocity, thus

$$\frac{\partial \xi}{\partial t} = na \cos n(t - x/c) \text{ or } \frac{\partial \xi}{\partial t} = -c\partial \xi/\partial x.$$
 (5)

Differentiating again, we obtain the acceleration

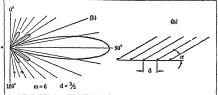

$$\frac{\partial^2 \xi}{\partial t^2} = -n^2 a \sin n(t - x/c) \quad \text{or} \quad \frac{\partial^2 \xi}{\partial t^2} = c^2 \frac{\partial^2 \xi}{\partial x^2}. \tag{6}$$

whence

in terms of wave velocity c and the slope and curvature of the displacement curve. Equation (6) is the differential equation which characterises wave motion. Its complete solution is

$$\xi = f(ct - x) + F(ct + x) \tag{6a}$$

which represents two independent systems of waves travelling in opposite directions with the same velocity c. This velocity is, within

FROM STENZEL IN "ELECKTRISCHE NACHRICHTER-TECHNIK" (WEIDMANN) FIG. 8

certain limits entirely independent of the form of the wave, being independent of wave-length \( \lambda \) and amplitude a. Within these limits, the velocity is determined solely by the physical properties of the medium. As we shall see, these properties are density and elasticity, corresponding to the factors mass and stiffness in the case of the vibrations of a particle. As the wave travels through the medium the volume and density fluctuate locally, these fluctuations being controlled by the properties of the medium and the applied forces. The following definitions are important:-

Dilatation  $\Delta$  is the ratio of the increment of volume  $\delta v$  to the original volume  $v_o$ , thus

$$\Delta = \partial v / v_o$$
 and  $v = v_o(\tau + \Delta)$ . (7)

Condensation s is the ratio of increment of the density  $\partial \rho$  to the original density  $\rho_0$  thus

$$s = \partial \rho / \rho_o$$
 and  $\rho = \rho_o(1+s)$  (8)

since 
$$\rho v = \rho_o v_o$$
 and  $(x+s)(x+\Delta) = x$  (8a)

and  $s = -\Delta$  neglecting  $s\Delta$  as a small second order quantity. Volume or Cubic Elasticity κ sometimes known as "bulk modulus" of elasticity.

$$\kappa = \delta p / \delta v / v_o = -v_o \delta p / \delta v = \delta p / s$$
 (9)

where  $\delta \phi$  is the stress and  $\delta v$  the strain; whence we have, for small variations of s,

$$p = p_o + \kappa s$$
 (10)

Compressibility C is the reciprocal of K. Thus

$$C = -1/v_o \cdot \delta v/\delta p = 1/\kappa \tag{11}$$

In the case of plane-waves travelling along the axis of x, the displacements of planes normally at x and  $x+\delta x$  will, at a time t, be  $\xi$  and  $\xi + \delta x \cdot \partial \xi / \partial x$  respectively. The thickness of the layer bounded by the two planes is therefore changed from  $\delta x$  to  $(1+\partial \xi/\partial x)\delta x$ . Consequently the dilatation  $\Delta = \partial \xi/\partial x = -s$ . The mass of unit area of the layer is  $p_0 \delta x$ . If the excess pressure on the  $(x+\delta x)$  face is  $\delta p$  we may equate this force to the product of the acceleration and the mass of the layer, thus  $\rho_0 \delta x \cdot \partial^2 \xi / \partial t^2 = -\delta p$  or  $\partial^2 \xi / \partial t^2 = -\delta p / \rho_0 \delta x$ . Now  $\delta p = \kappa s$  from (10), and  $s = -\partial \xi/\partial x$ ,

$$\frac{\partial^2 \xi}{\partial t^2} = \kappa / \rho_o \cdot \partial^2 \xi / \partial x^2 \qquad (12)$$

$$c = \sqrt{(\kappa / \rho_o)} \qquad (13)$$

or writing

$$\frac{\partial^2 \xi}{\partial a} = c^2 \frac{\partial^2 \xi}{\partial a^2} \tag{14}$$

which is equation (6) above, the complete solution being given in (6a). The velocity of plane-waves in the medium is therefore equal to  $\sqrt{(\kappa/\rho)}$ . The above method of treatment applies to all cases of transmission of small amplitude plane-waves in solid,

Relations (5) and (6) give the particle velocity and acceleration liquid, or ges, provided the appropriate modulus of elasticity is used. The bulk modulus  $\kappa$  is applicable only to large masses of fluid, where change of volume but not change of shape can take place. For a solid in bulk  $\kappa$  must be replaced by  $(\kappa + \frac{4}{3} \cdot \mu)$ where  $\mu$  is the rigidity whilst for a solid rod Young's modulus E is the appropriate elastic constant

Kinetic Energy in Plane-Waves. Intensity.—The rate of transfer of energy per unit area of cross section of the wave may be regarded as a physical measure of the intensity of the sound transmitted. The kinetic energy of a layer of unit area and thickness  $\delta x$  is  $\delta E = \frac{1}{2} \rho_c \, \delta x (\partial \xi / \partial t)^2$ . The maximum value of  $\partial \xi / \partial t$  is na (from eqn. [5]). Consequently the maximum kinetic energy per unit area and unit length (i.e. unit volume) of the wave =  $\frac{1}{2}\rho_0 n^2 a^2 - (15)$ . Since the sum of kinetic and potential energies is a constant,  $\frac{1}{2}\rho_o n^2 a^2$  must also be the total energy of the wave motion per unit volume. This quantity may be described as the energy density in the wave. Now the wave travels a distance c per second, therefore the transmission of energy per second per unit area of wave-front =  $\frac{1}{2}$ ,  $\rho n^2 a^2 c$  (16). This may be regarded as a measure of the intensity of the sound-wave. The intensity is therefore equal to the product of energy density  $(\frac{1}{2} \cdot \rho n^2 a^2)$  and wave velocity c. The maximum particle velocity \$\partial \eta d t\$ is from (5) equal to na and the maximum condensation

$$s = -\partial \xi / \partial x_{\text{max.}} = na/c,$$

that is, equal to the maximum particle velocity divided by the wave velocity. The expression for the intensity may therefore be written =  $\frac{1}{2} \cdot \rho c^3 s^2_{max}$ . Now

$$c^2 = \kappa/\rho$$
 and  $\delta p_{max.} = \kappa s_{max.}$ 

therefore the intensity or energy flow/sec. =  $(\delta \rho_{\text{max.}})^2/2\rho c$  (17) a useful expression giving the intensity of the sound-wave in terms of maximum pressure variation in the path of the wave.
Power of Sound Source. Radiation Impedance.—The

energy thus present in the sound-wave must be derived from the vibrating source. The rate at which the source does work, that is the power of the source, in producing sound-waves, is equal to the product of pressure variation and particle velocity, i.e., to  $\delta p \times \partial \xi / \partial t$  per unit area of wave-front. Now

$$\delta p = \kappa s = \kappa/c \cdot \partial \xi/\partial t$$
, and  $c = \sqrt{\kappa/\rho}$   
 $\delta p = \sqrt{\kappa \rho \cdot \partial \xi/\partial t}$ . (18)

Therefore the power expended by the source per unit area of wavefront =  $\sqrt{(\kappa\rho) \cdot (\partial \xi/\partial t)^2}$  (19). The relations expressed in (18) and (19) are closely analogous to the relations between e.m.f., current, and resistance in electrical circuits. If we regard  $\delta p$ ,  $\sqrt{\kappa p}$ , and  $\partial \xi/\partial t$  as corresponding to e.m.f. E, resistance (or impedance) R, and current i respectively we see that eqn. (18) is the mechanical analogue of Ohm's law in electricity, and that (19) is analogous to power dissipation Ri2 in an electrical circuit. The quantity Vκρ or ρc is consequently designated the radiation impedance per unit area of the medium transmitting the sound-wave. This quantity is important in the consideration of the transmission of sound waves through a succession of different media (see p. 18).

Spherical-Waves.- The results derived above for the energy in plane-waves hold equally well for spherical-waves at a sufficient distance from the source. Elementary considerations at once indicate that the energy density in the wave will vary inversely as the square of the distance from a point source of spherical-waves, whence it may be inferred that the amplitude. (of displacement, pressure or condensation) will vary inversely as the distance. This assumes, of course, that the amplitudes are small at all parts of the wave, and that there is no loss of energy due to viscosity, heat conduction and similar causes.

As in the case of plane-waves, it may be shown that the intensity at a point in the wave is given by  $(\delta p_{\text{max.}})^2/2\rho c$ .

Single and Double Sources. Energy Emission from Solid Vibrators .- A simple point source is a theoretical abstraction, but in practical cases where the source is a vibrating surface of appreciable area, each element of this area may be regarded as a simple source of spherical-waves, and the effect of the source as a whole obtained by integrating the effects of the elementary areas. Again, many vibrating bodies are not simple sources. For example a diaphragm radiating sound to air on both sides is, at any particular instant, sending out a compression pulse on one side and a rarefaction pulse on the other-thus behaving like two sources near together and in opposite phase; in other words acting like a double source. The prongs of a tuning fork each act as double sources in a similar way. Lamb (Dynamical Theory of Sound) shows that the rate of energy emission, or power, of a simple source is equal to  $\rho n^2 A^2 / 8\pi c$ , where  $\rho$  and care the density and velocity of sound in the surrounding medium,  $n/2\pi$  is the frequency, and A is the "strength" of the source (i.e., the maximum rate of emission of fluid at the source); the power of a double source is equal to  $\rho n^4 B^2/24\pi c^3$ , B being the "strength" of the double source. In both cases it will be seen that the rate of energy emission increases rapidly with increasing frequency. For the same strength and frequency, the energy emitted in different media will vary directly as the density and inversely as the wave-velocity (or the cube in the case of a double source). In gaseous media, where the velocity varies inversely as  $\sqrt{\rho}$ , the energy emission at constant frequency will vary inversely as (wave-velocity)<sup>3</sup> and (wave-velocity)<sup>5</sup> respectively in the two cases. These deductions account for the apparent feebleness of a bell or a tuning fork when vibrating in hydrogen as compared with air. The wave-velocity in hydrogen is 3.9 times that in air, therefore the energy emission from the same strength of source will be (3.9)5 or 900 times as great in air as in hydrogen. Another example:-the relative densities and wave-velocities for air and water are 1/770 and 1/4.4 respectively-the energy emission, on these grounds, being, for sources of the same strength and frequency, about 3,400 times as great in water as in air. The loading effect of the water and the limitations of output of sound generators must also be considered in dealing with actual cases. The quantities A and B in the above relations, denoting "strength" of source involve the area and form of the vibrating surface, amplitude and frequency. There is consequently for the same amplitude and frequency an increased rate of energy emission with increase of area in contact with the medium-exemplified by the increase of sound emitted when a tuning fork is brought into contact with a sounding board like the top of a table. The sounding board of a piano or a violin radiates practically all the vibrational energy of the strings, the damping of the latter being increased accordingly.

In designing "sound generators" it is important to observe that the sound energy radiated bears a definite relation to the total energy available at the source. The conditions governing efficiency in this connection are similar to the analogous case of an electrical generator supplying power to an external circuit.

"Local Flow."—When the vibrations of a solid body immersed in a fluid medium are very slow, the fluid behaves as if it were incompressible and simply flows locally from one surface of the "double source" to the other surface in opposite phase. In that case no sensible vibration is transmitted through the medium. As the vibrations increase in frequency the local flow is reduced, whilst true alternating pressure-waves, i.e., sound-waves, are set up in the medium. Again, at constant frequency, the higher the velocity of sound in the medium, the more nearly does the medium approach incompressibility, consequently the local flow is greater and less energy is radiated as sound.

On all grounds it is clearly preferable to use the simple source rather than the double source type of sound generator, for the local flow is reduced and there is no neutralising effect due to "out of phase vibrations" from a neighbouring surface. The increase of sound radiated from a tuning fork when "local flow" is reduced, may easily be demonstrated (see fig. 9). A piece of cardboard is held with one edge parallel and close to a prong of the vibrating fork, In positions A and B no effect is produced, whereas at C the sound is considerably increased in intensity.

The Principle of Superposition.—Huyghens first drew attention to the fact that the passage of one beam of light through an

aperture is in no way affected by the passage of another beam through the same aperture. It is a commonplace observation that any number of sound-waves may cross the same air space at the same time without the slightest evidence of confusion due to overlapping. This independence of the separate waves is explained by the principle of superposition, according to which the resultant effect of a number of displacements may be obtained by vector addition. The validity of this important prin-

ciple is dependent on the assumption that the elastic properties of the medium are such that the stresses are linear functions of the strains—a condition which is fulfilled in the case of small-amplitude sound-waves.

Huyghens' Secondary Waves.—Another important principle to Huyghens is the following:—The wave-front of. a, disturbance may at any instant be obtained as the envelope of the secondary waves proceeding from all points of the wave-front at some preceding instant. Thus the disturbance diverging from a point source may at any time t be regarded as represented by a thin spherical shell of radius ct, each point of which now serves as the origin of further spherical disturbances, the envelope of which becomes the new wave-front.

#### VELOCITY OF SOUND

It has already been shown that the velocity of sound-waves of small amplitude in an unlimited fluid medium is given by  $\sqrt{(\kappa/\rho)}$  where  $\kappa$  is the bulk modulus of elasticity and  $\rho$  the density of the medium. In the case of a solid in bulk,  $\kappa$  must be replaced by  $(\kappa + \frac{4}{\mu}\nu)$  where  $\mu$  is the rigidity of the solid. In special cases where the volume of material is limited, e.g., in solid bars or columns of liquid in tubes, it is important that the appropriate elastic constant be chosen.

In Gases.—When a gas is compressed it is heated, and when rarefied it is cooled. If the heating or cooling effects are not neutralised by removal or supply of heat, e.g., by convection, then the temperature of the gas will rise or fall accordingly. In ordinary sound-waves the alternate condensations and rarefactions take place so rapidly that there is no time for a transfer of heat between adjacent layers of gas. Consequently the temperature rises and falls with the same frequency as the waves of pressure. Such conditions are described thermodynamically as adiabatic. In an adiabatic compression, the relation between pressure p and density  $\rho$  of the gas is  $p/\rho \tau = \text{constant}$ , that is  $p/p_0 = (\rho/\rho_0)^{\gamma}$  where  $p_0, \rho_0$  and p refer to initial and final states of pressure and density, and  $\gamma$  is the ratio of specific heats of the gas. Thus  $(\tau + \beta p/\rho_0) = (\tau + \delta \rho/\rho_0)\tau = (\tau + \gamma s)$  for small values of the condensation  $s(=\delta \rho/\rho)$ . Now  $\kappa = \delta p/s$  (see equation 9). Therefore  $\kappa = \gamma p_0$ . Consequently the velocity of sound is given by

$$C = \sqrt{(k/\rho)} = \sqrt{(\gamma p_0/\rho_0)}. \tag{20}$$

Now Boyle's law indicates that  $t/\rho$  is a constant at constant temperature, consequently the velocity is independent of the pressure of the gas, for the density  $\rho$  changes in proportion to the pressure  $\rho$ . Taking  $\rho_0 = 10^6$  dynes/cm.<sup>2</sup> and  $\rho_0 = 0.00129$ , and assuming

 $\gamma = 1.41$  for air, we obtain a value for the velocity

$$c=3.31\times10^4$$
 cms./sec. at o° C.

This is in good agreement with observation.

Change of Velocity with Temperature.—Since  $\rho\theta = \rho_o/(\mathbf{x} + \alpha\theta)$  where  $\alpha$  is the temperature coefficient of volume expansion at constant pressure, and  $\theta$  is the temperature in degrees centigrade, we have  $c_\theta = \sqrt{(\gamma \rho_o(\mathbf{x} + \alpha\theta))/\rho_o|} = c_o\sqrt{(\mathbf{x} + \alpha\theta)}$ . Now for any gas  $\alpha = \mathbf{x}/273$  per degree centigrade nearly, therefore

$$c_{\theta}/c_{o} = \sqrt{T/T_{o}} \tag{21}$$

where T and T<sub>o</sub> are the absolute temperatures. That is, the velocity varies directly as the square root of the absolute temperature. The velocity given by (20) is independent of frequency, but is dependent on the nature of the gas. The velocity varies inversely

as the square root of the density, provided  $\gamma$  is the same—thus the velocity is four times as great in hydrogen as in oxygen.

Experimental Determinations of Velocity of Sound in Free Air.-The velocity of sound as measured in free air is affected by the wind, being greater with the wind than against it; in the first case the sum, and in the second the difference, of the velocities of the sound and the wind. It is also affected by humidity. The wind-velocity may be eliminated from the result by the method of reciprocal observation-the sound being produced first at one end and then at the other of a measured base line with a receiver also at each end. Alternatively the wind-velocity may be measured directly and a correction applied to the observed velocity of the sound. The latter method has been employed by Esclangon (Comptes Rendus, Jan. 20, 1919). The sound-waves from guns of various calibres were received by sensitive electrical sound-detectors at 1400 m. and 14000 m. along the same line. The time intervals were measured to ±0.002 second, the observations being made under various conditions of wind and humidity. The final result for the speed of sound in dry air at 15°C. was 339.9 metres per second which compares well with Regnault's value 339.7 metres/sec. (1863). Measurements of the velocity of sound at different levels (on mountain heights and plains) confirm the theory that there is no change of velocity with pressure. Observations at low temperatures in the Arctic give a value  $c_{\theta} = (333 + 0.6\theta)$  metres/sec. at  $\theta^{\circ}$ C. Other methods of measuring the velocity in free air are:-(1) Echo methods—the time t between the transmission of a sound and arrival of its echo from a reflector at a distance d being measured whence velocity = 2d/t, (2) Coincidence Method—The sound is transmitted at regular, accurately known, time intervals simultaneously from two points at a known variable distance apart. When close together, the sounds are heard together but when one is moved further away the sounds are separated by an interval, at first increasing and then decreasing, till coincidence is again established. The difference in distance between two such positions of coincidence, combined with a knowledge of the time intervals, gives a value of the velocity.

Probably the most accurate determinations were made during the war in connection with gun sound-ranging. Two sensitive resonant hot-wire microphones, at a known distance apart, received the gun-sounds which were automatically recorded by means of an Einthoven string galvanometer, the time intervals being measured to 0-001 second. A large number of such observations, under different atmospheric conditions (wind, temperature and humidity), gave a value 337·16 m/sec. at 10°C. in dry air, and 337·6 m/sec. at 10°C. in dry are supported by the effect of humidity, producing a slight change of density, being therefore very slight.

Velocity in Tubes or Small Volumes of Gas. Kundt's Dust Tube When a gas is only obtainable in small quantities the method of velocity measurement is entirely changed. best method available in these circumstances is one which is due to the work of Kundt. The gas is confined to a cylindrical tube containing a sprinkling of fine dry powder (lycopodium seed or cork dust) and is set into resonant vibration by any convenient means, e.g., by the longitudinal vibrations of a rod one end of which is inserted in the tube, or by the vibrations of the glass tube which contains the gas. The dust is heaped up in a repeated pattern indicating the nodes and loops in the vibrating gas column. Rayleigh and Ramsey used this method to determine the ratio of specific heats  $\gamma$  of the rare gases argon and helium. The velocity c in a gas is given by  $\sqrt{(\gamma p/\rho)}$  where p is the pressure and  $\rho$  the density. The value of  $\gamma$  found for the rare monotonic gases was 1.66. Kundt finally used a double-tube apparatus, in which stationary waves were produced simultaneously in two different gases by means of the same vibrating rod. The ratio of velocities in gas (1), rod, and gas (2), being equal to the ratio  $\lambda_1:\lambda_r:\lambda_2$ , the values of  $\lambda_1$  and  $\lambda_2$  are obtained from twice the nodal separation (indicated by the dust heaps), and the value of  $\lambda_r$  is equal to twice the length l of the rod when sounding its fundamental longitudinal vibration. When the frequency

N is determined (by monochord and tuning fork, or by a siren) the velocities c in the gas and the rod are known in absolute measure, for  $c_{gas} = N\lambda_{gas}$  and  $c_{rod} = N\lambda_{rod} = 2Nl$ . Alternatively the vibrations may be communicated to the gas by means of a steel diaphragm (a telephone earpiece) one end closed and excited electromagnetically, the frequency being varied until resonance is set up in the gas contained in the tube. This method has obvious advantages over the original "rod" excitation. Using a short steel bar and exciting the vibrations by striking one end, Lang (Proc. Roy. Soc., Canada, 1922) has observed the nodes and antinodes in a Kundt's tube up to a frequency of 50,000 cycles/sec. The mean velocity of sound in the air contained in the tube (1.4 cms. dia.) was found to be 339.3 metres/sec. at 22.8° C., and in the steel bar 5120 m/sec. approximately. Kundt's tube method of measuring sound-velocities, and indirectly, the ratio of specific heats of gases, has been applied by Dixon, Partington and others to vapours and gases at various temperatures, and as a means of measuring temperature coefficients of sound-velocity.

In Liquids.—As in the case of gases the velocity of sound in liquids is given by  $\sqrt{(\kappa/\rho)}$ , which  $\kappa$  is the adiabatic bulk modulus of elasticity. Taking the isothermal compressibility C of fresh water to be  $49\times10^{-12}$  per dyne/cm.<sup>2</sup>, at  $15^{\circ}$  C. the bulk modulus  $\kappa(=1/c)=2\cdot04\times10^{10}$ , and the velocity

 $\sqrt{(\kappa/\rho)} = 1,427 \text{ metres/sec.}$ 

The value found by Colladon and Sturm (1826) in Lake Geneva was 1435 m./sec. at a temperature of 8° C.

Velocity of Sound in the Sea .- The velocity of sound, particularly explosion-waves, has been measured in the sea by a number of observers with considerable accuracy. Marti (Comptes Rendus, Aug. 1919) used three under-water microphones (hydrophones) in a straight line in Cherbourg roadstead, the total base line being 1800 metres. The positions were accurately determined by theodolites. The passage of the sound-wave due to an explosion under water in line with the hydrophones, was registered by an electric chronograph with smoked paper and tuning fork time-trace. At a temperature of 14.5°C. the velocity was found to be 1503.5 metres/sec. in sea water of density 1.0245 gram/cm.3 More recently a careful series of observations has been made by Wood, Browne and Cochrane near Dover with four hydrophones covering a base-line of twelve miles in the sea (Roy. Soc. Proc., May 1923). Accurate temperature and salinity observations were made at points along the base line, and a new method (multiple charge method) devised to obviate errors arising through firing the charge at a point not quite in line with the base of hydrophones. The time intervals of passage of the explosion wave between pairs of hydrophones was recorded on four strings of a six stringed Einthoven galvanometer (photographic), the ticks of an accurate chronometer on the fifth, and a wireless signal sent from a destroyer at the instant of firing the charge was recorded on the sixth string. Thus the record showed to an accuracy of ± oor second the various time differences and the total time of travel of the explosion-wave to each receiver. The results obtained in summer and winter were 1510-4 m/sec. at 16-95°C. and 1477.3 m/sec. at 7°C. respectively, the salinity being 35%0 in both cases. (The theoretical values calculated by D. J. Mathews [see Tables for Velocity of Sound in Fresh and Sea Water-Stationery Office Publication H.D. 282 1927] are 1510-4 m/sec. and 1476.1m/sec. respectively.) experimental results are expressed by the relation,

$$velocity = 4756 + 13.8 \ t - 0.12 \ t^2 \ ft. \ per \ sec.$$
 (22)

at  $35\%_0$  salinity in  $\%_0$  at the temperature  $f^*$ C). The ratio of specific heats (isothermal and adiabatic) for sea water, deduced from these measurements, is r-cop4 as compared with r-copo obtained from thermodynamic data. The adiabatic compressibility at  $16\cdot95^\circ$ C and  $35\%_0$  salinity is  $43\cdot145\times10^{-12}$  per dyne as compared with Ekmann's isothermal value  $42\cdot744\times10^{-12}$  per dyne.

Liquids in Tubes.—As in the case of gas-filled tubes stationary waves may be set up in tubes filled with liquid. On account of the small compressibility of a liquid compared with that of gas, however, a correction is required due to the yielding of the walls of the containing tube. This yielding produces an apparent lowering of the wave velocity—the lowering being smaller the thicker the tube. If  $c_o$  be the theoretical velocity of sound in the liquid, and c the actual velocity in the liquid in a tube of small thickness k then

$$c_o = c\sqrt{1 + 2\kappa a/hE}$$
 (23)

where a is the internal radius, K the bulk modulus for the liquid, and E the value of Young's modulus for the material of the tube (see Lamb's Sound, p. 174). In the other extreme, when the walls are very thick

$$c_o/c = \sqrt{[(\kappa + \mu)/\mu]} \tag{24}$$

where  $\mu$  is the rigidity of the material of the tube. Kundt and Lehmann succeeded in obtaining "dust" (fine iron filings) figures in liquids, as in gases, and thus measured the velocity of sound in tubes of different diameters and thickness. Application of Lamb's formula to their experimental values gives a mean value 1436 m/sec. at 19°C for the velocity of sound in open water. At frequencies within the audible range, the resonance of a liquid column can be observed by ear. The vibration is readily excited for example, by means of a steel diaphragm electro-magnetically maintained by current of variable frequency from a valve oscillator.

When the wave-length of the sound in the liquid is sufficiently small compared with the diameter of the tube the "correction" disappears. Hubbard and Loomis (Nature, Aug. 6, 1927 and Phil. Mag., June 1928) using a quartz oscillator 100 mm. diameter emitting plane-waves at frequencies between 200,000 and 400,000, have determined the velocity of sound in various liquids in a tube, with an accuracy of 1 in 3,000. The results for fresh and salt water at different temperatures agree well with the values obtained by other observers for these liquids in bulk.

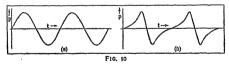

In Solids.—The velocity of sound in a solid rod of length l is very simply determined by observing the frequency N of its longitudinal vibration, the rod being clamped at the midpoint. The velocity is equal to  $N\lambda$  or 2Nl. The rod may be excited mechanically by striking or rubbing, or electro-magnetically. The velocity in steel or glass, for example, is about 5×10<sup>5</sup> cms./sec. as compared with 0.33 × 105 cm./sec. in air and 1.5 × 105 cm./sec. in water. The values of the velocity determined experimentally in this way agree very closely with the calculated velocities  $\sqrt{(E/\rho)}$  where E is Young's modulus of elasticity. The converse of the method is therefore convenient as a means of determining E approximately. Lang (loc. cit.) has determined the velocity in short steel rods (5 cms.) vibrating at a frequency of 50,000 using Kundt's tube as a means of estimating the frequency. The values of velocity at supersonic frequencies are found to be the same as at audible frequencies. Apart from seismic observations there is little or no experimental data relating to the velocity of sound-waves in solids in bulk.

Velocity of Waves of Large-Amplitude.-Explosion-Waves .- Hitherto it has been assumed that the displacementamplitude and condensation s are always small, and that the wave travels through the medium with velocity  $c = \sqrt{(\kappa/\rho)}$ without change of type. If, however, the condensation becomes large, as in an explosion-wave, the velocity may be considerably modified for the curve connecting pressure p and density  $\rho$  is not a straight line. The bulk modulus,  $\kappa = -v_0 \partial p/\partial v = \rho_0 \partial p/\partial \rho$ , increases as the density  $\rho$  is increased by compression, and diminishes as the density is reduced. Consequently the compression wave travels faster and the rarefaction slower than a small-amplitude" sound-wave. The result is a change of waveform as a large-amplitude wave travels through the medium. Lamb (Sound, p. 177) shows that the velocity of propagation is c(x+s) relative to the undisturbed medium (or  $c[x+s]^{\frac{1}{2}(\gamma+1)}$ in the adiabatic case) indicating increase of velocity with increase of condensation s. The parts of the wave of greater density

therefore gain continuously on those where it is less-i.e., the crests tend to overtake the troughs, as indicated graphically in figs. 10 a and b. The wave becomes steeper in front and more gradual behind. A continuation of such a process would eventually lead to a discontinuity when the wave-front becomes vertical-a condition which is physically impossible. As Rayleigh has remarked, such a tendency is held in check by the divergence of the wave and the influence of viscosity tending to diminish amplitudes and therefore reduce the velocity to its "normal" value. As an illustration, change of type in a progressive wave may be observed when sea waves approach a shelving beach. Here the crests gain on the troughs and the wave "fronts" become steeper and steeper until they curve over and break. A large amplitude explosion wave has initially a velocity considerably greater than ordinary sound-waves, gradually approaching this latter value as the distance from the origin increases. Regnault found that explosion-sounds increased in velocity with increase in the intensity of the explosion. Foley (Nat. Acad. Soc. Proc., June, 1920) showed that the velocity of sound from an intense electric spark varied from 660 m./sec. at a distance of 3.2 mm. from the spark to 380 m./sec. at a distance of 18 metres. The shadow of the high pressure region near the wave-front of the sound-pulse was photographed at known short time intervals after the instant of production of the spark, the velocities at various distances being deduced therefrom.

Shell-Waves. Onde de choc .- When a bullet or a shell, travelling with a velocity greater than that of sound, passes an observer it makes a sound like the crack of an explosion-described by the French as "onde de choc." The tips of the propeller of an aeroplane often exceed the velocity of sound and emit sounds of this nature as they revolve. In the case of a low speed bullet, the air at the nose is compressed, the compression being transmitted in all directions with the velocity of sound (approximately 330m/sec. in air). If however, the speed of the bullet is greater than the velocity of sound the condensation of the air at the nose can be transmitted laterally but not forwards. Photographs taken of bullets while in flight show this clearly and reveal the existence of two wave-fronts, one at the head and the other at the base of the projectile. The former can be simply explained on Huyghens' principle of secondary wavelets. If the velocity of sound at the nose of the bullet were normal, the wave-front would be a cone of semi-angle sin-1c/V (c normal velocity of sound and V velocity of projectile). But the velocity of sound increases with increased amplitude of condensation, consequently the wave-front is a blunted cone, as actually recorded in the Plate; see Fig. 2. From observations of the changing direction of the "onde de choc" it is possible to trace the bullet or shell to its source. (See Mallock, Proc. Rov. Soc., p. 115. 1908.) This method was used in the war to locate enemy guns.

Velocity of High Frequency Sounds.—Using a quartz piezo-electric oscillator (see p. 12) as a source of high frequency vibrations, G. W. Pierce (Proc. Amer. Acad., vol. 60, Oct. 1925) determined with considerable accuracy the velocity of sound in

air and carbon dioxide by the stationary-wave method. He found that the velocity of sound in air at °°C has the values 33.04, 432.47 and 33.64 metres/sec. at frequencies 1,000, 50,000 and 1.5×10<sup>8</sup> p.p.s. respectively. The effect of humidity was negligible, at 80% humidity differing by less than 0.02% from the velocity in dry air. In CO<sub>2</sub> the velocity at °°C was found to be 258.82 m/sec. at a frequency of 42,000 cycles/sec. increasing to 260.15 m/sec. at 200,000 cycles/sec. This gas becomes opaque to sound-waves at still higher frequencies. Boyle and Taylor (Proc. Roy. Soc., Canada, 1025) observed a diminution of velocity

of high frequency sounds in water at 16°C from  $r \cdot g_1 \times ro^5$  cms/sec. to  $r \cdot 42 \times ro^5$  cms/sec. at frequencies 43,000 and 508,000 cycles/sec. respectively. The measurements were made in a small tank. The velocity in a viscous oil was found to be the same at 570,000 cycles/sec. as at low frequencies. Lang (Roy. Soc., Canada, 1922) found no change in the velocity of sound in steel bars at any frequency up to 50,000 cycles/sec. Reference has already been made (p. 22) to the piezo-electric measurements of Hubbard and Loomis on the velocity of sounds of frequency  $3 \times ro^5$  in various liquids contained in tubes.

Change of Medium. Reflection and Transmission.—As in the case of light, when a wave of sound meets the surface of separation of two different media it is partially reflected, and a wave travels back (in the negative direction) through the "incident" medium, with the same velocity as it approached the bounding surface. The laws of reflection are the same as applied to Mght waves—angles of incidence and reflection being equal and in the same plane. With sound-waves however, we have often to deal with wave-lengths which are comparable with the dimensions of reflecting objects; the phenomena must then eventually be regarded primarily as diffraction. In the cases which we are now considering the wave-length may be regarded as small, or the reflector large, the ordinary optical laws being applicable.

Reflection of Plane-Waves at the Boundary of Two Extended Media.—It is shown in text-books of sound (Rayleigh, vol. [ii, p. 81) that the relative amplitudes r and a of the reflected and incident waves are given by

$$\frac{r}{a} = \frac{\rho_2/\rho_1 - \cot \theta_2/\cot \theta_1}{\rho_2/\rho_1 + \cot \theta_2/\cot \theta_1}$$
(25)

where  $\rho_1$  and  $\rho_2$  are the respective densities of the first (incident) and second (transmitting) media and  $\theta_1$  and  $\theta_2$  are the angles of incidence and reflection. The law of sixes of optical refraction holds in this case also, and we have  $\sin\theta_1/\sin\theta_2 = c_1/c_8$ , where  $c_1$  and  $c_2$  are the velocities in the first and second media. Consequently (25) may be written

$$\frac{\sigma}{a} = \frac{\frac{\rho_2}{\rho_1} - \frac{c_1 \cos \theta_2}{c_2 \cos \theta_1}}{\frac{\rho_2}{\rho_2} + \frac{c_1 \cos \theta_2}{c_1 \cos \theta_2}}$$
(26)

which becomes

$$\frac{r}{a} = \frac{\rho_2 c_2 - \rho_1 c_1}{\rho_2 c_2 + \rho_1 c_1}$$
(27)

at "normal" incidence (when  $\theta_1 = \theta_2 = 0$ ). If the velocity in medium (2) be greater than in medium (1), the incident waves being in the slower velocity medium, there will be a critical angle of incidence ( $\sin \theta_1 = c_1/c_2$ ) which, if exceeded, will result in total reflection.

As an example, let air and water be the media (x) and (2), sound waves being incident normally on the surface of the water. Equation (27) which expresses the reflection-amplitude in terms of the radiation impedances  $\rho c (= \sqrt{\kappa} \rho)$  per unit area of the two media (see above) gives r = 0.99940, since the values of  $\rho$  for water and air are  $14 \times 10^4$  and 40 respectively. In such a case, where the radiation impedances are widely different, there is almost complete reflection, even at normal incidence. The transmission is a maximum and reflection zero when  $\rho \iota c_1 = \rho_2 c_2$ , that is, when the radiation impedances of the two media are equal.

Reflection of Plane Waves from a Plate of Finite Thickness.—This case is analogous to the optical example of reflection from a thick plate of glass—the reflected wave being the resultant of multiple reflections at the two bounding surfaces. The ratio of reflected and incident amplitudes for normal incidence now becomes

$$\frac{\mathbf{r}}{a} = \left(\frac{\rho_1 c_1}{\rho_2 c_2} - \frac{\rho_2 c_2}{\rho_1 c_1}\right) / \left\{ 4 \cot^2 \frac{2\pi l}{\lambda_2} + \left(\frac{\rho_1 c_1}{\rho_2 c_2} + \frac{\rho_2 c_2}{\rho_1 c_1}\right)^2 \right\}^{\frac{1}{2}}$$
 (28)

where l is the thickness of the plate and  $\lambda_2$  the wave-length of the sound in it,  $\rho_1 c_2$  and  $\rho_2 c_2$  being the respective radiation resistances

of the medium (1) and the plate (2). Boyle and Rawlinson (Proc. Roy. Soc., Canada, 1928) have deduced a more general expression for any angle of incidence, and have determined the "critical angle" at which total reflection occurs. It will be seen that the reflected-amplitude r fluctuates between zero and a maximum as the thickness of the plate varies. In the case where  $c_4 > c_1$  the reflected amplitude is zero when l = 0 or a multiple of  $\lambda/4$ , and reaches its maximum value when l is a multiple of  $\lambda/4$ . A quarter wave-plate consequently reflects a maximum and transmits a minimum of the incident sound-energy.

These relationships for the reflection of plane-waves from flat plates have been verified by Boyle and Taylor and Boyle and Lehmann in the case of high frequency sound-waves passing through water in which the plate was submerged. Equations (26) (27) and (28) indicate that solid media in air are practically perfect reflectors, whereas in water they are relatively good transmitters of sound. An air film in water or in a solid mass constitutes a perfect reflector, with a reversal of phase at reflection. The practical application of such deductions is dealt with by H. Brillié (Le Génie Civil, Aug. and Sept. 1919) in relation to the problem of sound-reception under water.

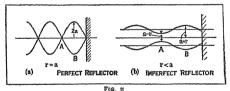

Stationary Waves.—Reflection and Absorption Coefficients of Materials. It has been shown in the case of strings that the resultant displacement y at a point in the stationary wave formed by combining the direct and reflected-waves is given by

$$y = a \cos n(t - x/c) - a \cos n(t + x/c) = 2a \sin nt \sin (nx/c).$$

The same relation applies to longitudinal-waves of condensation reflected normally from a plane perfectly reflecting obstacle. If, however, the obstacle is not a perfect reflector some of the incident sound energy is absorbed or transmitted. Consequently the reflected-amplitude r is less than a. The expression for y now becomes

$$y = (a+r) \sin nt \sin(nx/c) + (a-r) \cos nt \cos(nx/c)$$
 (29)

in the case of perfect reflection (r=a) we obtain the ordinary expression for stationary-waves. The general expression (2a) is applicable to all cases, and is represented by fig. 11. The incident energy is proportional to  $a^2$  and the reflected energy to  $r^2$ . The reflection coefficient of the obstacle is defined as the ratio  $r^2/a^2$ . Equation (2a) represents two superimposed stationarywaves of maximum-amplitudes (a+r) and (a-r) respectively, and displaced  $\pi/2$  in phase. Consequently the maximum and

minimum-amplitudes of the *resultant* stationary-wave are proportional to (a+r) and (a-r) respectively. If we write

$$\alpha = (a+r)$$
 and  $\beta = (a-r)$ ,

then the reflection coefficient

$$\frac{r^2}{a^2} = \left(\frac{\alpha - \beta}{\alpha + \beta}\right)^2 = \left(\frac{1 - \beta/\alpha}{1 + \beta/\alpha}\right)^2 \tag{30}$$

This expression for the reflection coefficient, in terms of the ratio min/max amplitude in the stationary-wave, serves as a basis for experimental methods of measuring the reflecting properties of materials and, of course, their absorption or transmission properties. The absorption coefficient (which is generally assumed to include transmission) is given by

$$(a^2-r^2)/a^2=4/(2+\alpha/\beta+\beta/\alpha)$$
.

This method of determining sound absorption coefficients of

materials was developed by Tuma (1902), Weisbach (1910) and Hawley Taylor (1913). More recently Paris (Roy. Soc., 1927) and Phys. Soc. Proc., 1927) has refined the experimental procedure by using the hot-wire microphone to obtain accurate values of the ratio  $\beta/a$ , and consequently of the reflection and absorption coefficients. The plane stationary-waves were produced in a tube closed at one end by the reflector under test. The absorption coefficient was found to increase with increasing thickness of the absorber (e.g., felt) and with increase in the frequency of the sound. Such measurements have an important application in the acoustics of buildings q.s. Stationary waves may readily be demonstrated when a high pitched sound, from a bird call or Galton's whistle, is reflected normally from a plane solid obstacle. A sensitive flame flares at all points in the path of the wave except at the nodes.

Echoes.—The direct reflection of a sound of short duration from a surface of large area such as a wall or a cliff results in what is familiarly known as "echo". The time-interval t between the initiation of a sound-impulse and the reception of the echo at the same point of observation is given by t=ad/c where d is the distance of the reflector and c is the velocity of sound in the intervening medium. Measurements of t will therefore lead to a value of the velocity c or the distance d according to which of these two quantities is previously known. The principle has important practical applications (e,g), see Echo Depth Sounding, p. 35) in

the measurement of distance.

Harmonic Echoes.—If the primary sound has a complex waveform, containing high harmonics of a fundamental tone, the component tones will be scattered or diffusely reflected in unequal proportions. The amplitude of the secondary-waves varies inversely as the square of the wave-length (and intensity as I/N), consequently the higher harmonics of the complex wave are scattered back in far greater proportion than the fundamental. To an observer near the source, therefore, the returning echo appears to be raised in pitch one or more octaves according

to the nature of the primary sound.

Reflectors as Sound Screens.—To produce shadows comparable with optical shadows, it is essential that the reflector should be large compared with the wave-length of the sound employed. The high pitched tick of a watch may be effectively screened by a relatively small reflector but the sound of a man's voice or of a motor horn requires a much larger screen. The wave-lengths in the two cases vary from a few inches to several feet, and the linear dimensions of the reflector must consequently vary in the same proportion to produce the same degree of screening. Behind the reflector the sound is generally found to have changed in quality, the high frequency components being more perfectly screened than the lower frequencies—on this account the sound appears to be "purified."

Musical Echoes from Palings. Echelon Reflectors. (Gratings).—If a sharp sound is made near one end of a row of palings, or similar "stepped" structure, the echo takes the form of a musical note. The successive palings each reflect the impulse (or, selectively, its higher harmonics) and the observer receives a succession of reflections which, if sufficiently rapid, blend into a musical note. The time intervals  $\delta t$  are equal to  $2\delta x/c$ , where  $\delta x$  is the path difference to the successive reflectors, consequently the frequency N of the note will approximate to  $C/2\delta x$  or some higher harmonic. If, for example, near a row of palings  $\delta x = 4$  inches, and c = 1 roo t/c, sec., N will be a multiple of  $t \cdot 65 \text{ cycles}/\text{sec}$ , i.e., a high pitched note. An echelon structure of this kind serves as the equivalent of a "grating" by which complex high frequency sounds might be analysed (see p. 26).

Reflection at Curved Surfaces. Spherical Mirrors.—It is shown in books on Optics that a parallel beam (plane-waves) of light when incident on a spherical mirror will be brought to a focus at a distance from the pole of the mirror equal to half the radius of curvature, and conversely a parallel beam of light emerges from such a mirror when a small source is placed at the focus. Similar results are observed with sound-waves of high frequency and reflectors of moderate dimensions.

Whispering Gallery Effects.-The well known whispering gallery of St. Paul's Cathedral, London, owes its peculiar acoustical properties to the reflection of sound by the walls. The gallery takes the form of a circle around the base of the dome. The exact mode of action is still a moot point. Rayleigh (Sound, vol. ii., p. 126) pointed out that the sound tends to creep round the inside of a curved wall, being continuously reflected by the wall, without ever getting far from it. whisper seems to creep round the gallery horizontally, not necessarily along the shorter arc, but rather along that arc towards which the whisperer faces. This is a consequence of the very unequal audibility of a whisper in front of, and behind the speaker. The abnormal loudness with which a whisper is heard is not confined to the position diametrically opposite to that occupied by the whisperer and therefore, it would appear, does not depend materially on the symmetry of the dome." It should be noted that whispers contain a higher proportion of high pitched sounds than ordinary speech, and whispering is heard more distinctly than ordinary conversation especially if the speaker looks along the gallery towards the listener. C. V. Raman (Ind. Assoc. Sci. Proc., 1922) describes an investigation of 5 whispering galleries in India which confirm a view held by Sabine of the importance of the inward slope of the wall of the gallery for giving the best effects, and the concentration by a spherical dome of a maximum sound at the opposite end of a diameter. Multiple sounds which are observed are shown not to be echoes, but sound-waves travelling circumferentially round the gallery several times before they are appreciably diminished in intensity.

Rayleigh suggests that the propagation of earthquake disturbances is probably affected by the curvature of the surface of the earth acting like a whispering gallery. It is not improbable also that sounds travelling long distances in the sea are dependent on a similar action, and on repeated reflection at the surface and bottom. Taking the depth of a sea as uniformly 24 fathoms (144 ft.) the maximum possible distance of direct propagation of a sound-wave in it will be 20; a miles approximately—whereas ranges 2 or 3 times this value have actually been observed in the North sea. The possibility of a curved path due to temperature gradients must also be considered in seeking an

explanation of these long ranges in the sea. Refraction of Sound-Waves.-The optical analogy which applies to reflection of sound may, as we have already seen, apply to refraction also. When plane-waves of sound cross the bounding surface between two different media having different wave-velocities c1 and c2 the direction of propagation is changed in accordance with the sine law, viz.,  $\sin \theta_1 / \sin \theta_2 = c_1 / c_2$  where  $\theta_1$  and  $\theta_2$  are the angles of incidence and refraction respectively. Hence the sound "rays" in passing from one medium to another are bent towards or away from the normal according as the velocity of the wave in the first medium is greater or less than in the second medium. Thus, for example, sound is refracted towards the normal when passing from air into CO<sub>2</sub>. "critical angle", when the sound is totally reflected, and there is no refracted beam, is given by  $\sin\theta_1=c_1/c_2$ . The critical angle from air to water,  $c_1 = 1,100$  ft./sec. and  $c_2 = 4760$  ft./sec., is therefore 1310 approximately; above this angle no sound whatever can enter the water (we have already shown, p. 23, that even at normal incidence the reflected amplitude is 0.99943 of the incident amplitude). From air to solid materials (steel, glass, wood, etc.)  $c_1/c_2 = 0.065$  approx. whence the critical angle is  $3\frac{1}{2}$ °. Sondhauss (1852) demonstrated the refraction of sound through prisms containing various gases, and determined the refractive index  $\mu$  relative to air,  $\mu = \sin \theta_1 / \sin \theta_2 = c_1 / c_2$ . He was also successful in demonstrating the focusing action of a convex lens of carbon dioxide enclosed in a thin envelope of collodion.

Refraction by Wind and Temperature Gradients.—It is well known that sound travels better with the wind than against it. This effect is due to the increase of velocity of the wind from the earth's surface upwards. The effective velocity of sound is equal to its normal velocity  $\sqrt{(\gamma p/\rho)}$  plus or minus the velocity of the medium. In still air the wave-front of a sound-beam will travel over the earth's surface parallel to its initial direction, say at right angles to the ground If, however, a wind is blowing in the same direction, the upper part of the wave where the wind velocity is greater, travels faster than that part near the ground, with the result that the wave-front tends to bend downwards towards the ground. An observer therefore hears by a direct ray which starts with a slightly upward inclination. Similarly a horizontal ray travelling against the wind is bent upwards and, at a moderate distance, passes over the head of an observer. A similar effect may be noticed when there is a gradual change in the temperature of the air from the ground upwards. The warmer the air, the greater the velocity of sound. If the temperature increases upwards, the wave-front will be bent downwards towards the ground; conversely, when the temperature diminishes upwards the sound-beam will be deflected upwards into the higher atmosphere and lost. The curvature of the ray is given by  $1/R = -1/c \cdot \partial c/\partial y$  where  $\partial c/\partial y$  is the velocity gradient with respect to height-this gradient may be positive or negative.

Audibility of Fog Signals. Tyndall (Phil. Trans., 1874) made extensive researches on the audibility of fog signals across the Channel from South Foreland, and came to the conclusion that "temperature refraction" and a "flocculent" condition of the atmosphere, arising from unequal heating or moisture, were responsible for large fluctuations in the observed ranges of audibility. Contrary to general opinion at the time Tyndall found that the presence of fog favoured the transmission of sound signals—the atmosphere being then in a more homogeneous condition, particularly in regard to temperature gradients. The problem of long-distance transmission of signals has recently been studied by King, Tucker, Paris and others. Using a doubly-resonated hot-wire microphone, Tucker and Paris have made intensity measurements at varying distances and orientations with respect to diaphones and sirens mounted in light-houses at sea. In a particular experiment it was found that the ratio of sound intensities at two miles from the source, with the wind and against it was 25 to 1. The effects of temperature refraction were also partly responsible for this high value of the ratio at such a short range. Certain fluctuations of intensity were ascribed to moving eddies in the atmosphere. Player, however, as a result of recent observations of a similar nature, reached the conclusion that humidity is the only factor in which the variations are at all comparable with the large and sudden variations in the range of audible transmission.

Zones of Silence. The sound of a large explosion is sometimes observed at very great distances, whilst at intermediate distances nothing at all is heard. Thus the explosion of a large ammunition dump in Holland (Jan. 1923) was recorded at a distance of 850 km, whereas at roo to 850 km, no sound could be detected. These intermediate zones of silence are not uncommon in such cases. They doubtless arise as a result of peculiar meteorological conditions at the time of the explosion. As we have seen, the action of temperature and wind gradients may cause upward or downward refraction of the sound. Esclangon (Comptes Rendus, 1924) has shown that these two factors are sufficient to account for one or a succession of zones of silence, with reinforcement of sound in particular directions. Zones of silence are in certain cases due to the interference between sound-waves reaching the observer by different paths. (See Interference above.)

Effect of Temperature Gradients on Sound Propagation Under Water.—The sea is a much more homogeneous medium for sound-transmission tnan the atmosphere. Sounds of moderate power may be heard at long ranges, 40 or 50 miles, without the corresponding fluctuations of intensity which are so troublesome in air. The effects of tidal currents (analogous to "wind"), say roft./sec, are in most cases negligible, the velocity of sound in water being about 5,000 ft./sec. Seasonal variations in range of signals have been observed (see H. Lichte, Phys. Zeits., Sept. 1919) these being ascribed to refraction produced by temperature gradients

in horizontal layers of the sea. Such a temperature gradient may cause a sound "ray" to curve upwards to the surface where it is reflected down again, only to rise once more. In this way it travels forward along a cycloidal or "festoon" type of track. A temperature gradient of opposite sign causes a bending downwards with analogous effects at the sea bed. Surface and bottom reflections play an important part in the long-range transmission of sound in the sea. With a particular sound-transmitter Lichte and Barkhausen (Ann. d. Physik, 62, July 1920) noted a change from 10 km. in summer to 20 km. in winter in the Baltic sea.

Interference.- The passage of sound-waves through a medium is in no way affected by the passage of other sound-waves through the same part of the medium. This important principle involving the independence of separate trains of waves is known as the Principle of Superposition and was first propounded by Huyghens in dealing with light-waves. The resultant displacement of a particle of the medium is obtained by adding the separate displacements vectorically (see p. 20). Thus two periodic motions of the same frequency, of amplitudes a1, and a<sub>2</sub>, and phase difference € combine to form a periodic motion having an amplitude whose square is  $(a_1^2 + \hat{a}_2^2 + 2a_1a_2 \cos \epsilon)$ . The principle of superposition applied to the squares of amplitudes (i.e., energies) would account for the first two terms only and the results would be erroneous. It is found under certain conditions that two trains of sound-waves may, at certain points in the medium, neutralize each other's effects and produce silence where previously there was a definite sound due to either of the trains of waves. Thus in the above case, if  $\epsilon = 180^{\circ}$ , i.e., the two independent sets of vibrations of the particle are in opposite phase cose=-r, and the resultant amplitude is  $(a_1-a_2)$ , which becomes zero when  $a_1=a_2$ ; if  $\epsilon=360^\circ$  or  $0^\circ$ ,  $\cos \epsilon = +1$  and the resultant-amplitude is  $(a_1+a_2)$  or 2a, when  $a_1=a_2$ . When the observed sound-distribution due to two or more wave-trains of sound is not found to be equal to the sum of the separate wave-trains, the latter are said to have inter-fered with each other and the phenomenon is described as interference. Interference is a direct result of the principle of superposition. The phenomena of interference may be observed in any smooth water surface which is disturbed simultaneously at two different points. J. H. Vincent has obtained very beautiful photographs of such effects on the surface of mercury (see Phil. Mag., 1897, 8 and 9). The crests and troughs of the two sets of ripples in certain places reintorce each other, whilst in others they neutralize; the result is a definite "interference pattern" superposed on the ordinary wave systems. When sounds of the same frequency and amplitude reach the ear by different paths, or originate with different phases, interference effects may readily be observed. Thus the waves sent out from the prongs of an ordinary tuning fork interfere, producing approximate silence in certain directions and increased intensity in others-the rise and fall of intensity, four times per revolution, as a vibrating fork is rotated near the ear is easily demonstrated. Any "doublesource" of sound, such as a vibrating diaphragm exposed on both sides, shows these effects. If sound is led from its source to a receiver by two tubes of equal diameter and length the two sets of waves will arrive together, i.e., in phase. If the length of one tube is gradually varied relatively to the other the path difference will be successively  $\lambda/2$ ,  $\lambda$ ,  $3\lambda/2$ ,  $2\lambda$ , and so on; the resultant effect at the receiver alternating between zero, and maximum. These phenomena can be demonstrated by means of a tuning fork and two tubes of adjustable length, with a common exit placed to the ear. Stationary-waves to which we have already referred (p. 23) form a good example of the interference between a primary and a reflected train of waves. Interference between the waves from two sources of sound of nearly equal frequency appears as an increase and decrease of intensity with time-known as the phenomenon of beats (see p. 6) and exemplified by two tuning forks of nearly equal pitch. In certain cases the zones of silence observed by Tyndall when listening on a ship to the sound of a fog siren on a neighbouring cliff, were ascribed to the interference between the direct sound beam with that reflected from the surface of the sea-if these the effect of the first zone, i.e., the same as if no obstacle at all paths differ by any odd multiple of half a wave-length the two trains of waves neutralize each other and the siren is not heard. Wood and Young (Proc. Roy. Soc., 100, 1921) observed interference zones under water due to a similar cause. Such effects are of considerable importance in the case of long distance sound transmission in the sea. The sound-wave is reflected with reversal of phase when it reaches the water-air surface. At a considerable distance from the source, the path difference between the direct and surface-reflected wave may become very small compared with the wave-length, resulting in almost complete neutralization. Fortunately, however, the surface of the sea is never smooth and the sea-bed reflects sound very efficiently. The bottom-reflected-wave may therefore, in certain cases, be solely responsible for the sound heard at long ranges.

Diffraction. Sound-Shadows - The bending of sound-waves round the edges of obstacles is one of the most familiar of everyday observations. If it were not for this effect, short distance intercommunication by means of sound would be much more difficult. Fast motor traffic on our roads is vitally dependent upon such a possibility at turnings and crossings. This bending of sound "round the corner" may be regarded as evidence of its nature as a form of wave motion; the effect being similar to that of "diffraction" in the case of light-waves. The sound-shadow and the geometrical shadow of an obstacle are therefore not coincident. The study of diffraction effects is greatly assisted by the use of a principle which is due to Huyghens:- The wave-front of a disturbance may at any instant be obtained as the envelope of the secondary-waves proceeding from all points of the wave-front at some preceding instant. A disturbance diverging from a point source with velocity c may at any time t1 be represented by a thin spherical shell. This shell may therefore be regarded as the disturbed region, and the disturbance at a subsequent time t2 determined by drawing spheres of radii  $c(t_2-t_1)$  round each point of the shell. The outer spherical envelope of these spheres will be the new wave-front at the instant t2. By this construction it will be found that the direction of advance of the wave is normal to the wave-front. Huyghens' principle of secondarywaves is directly applicable to diffraction problems provided that due allowance is made for the contribution of each surface element of the wave-front to the amplitude at the point P under consideration. This estimation of amplitude involves the use of a device due to Fresnel-in which the initial wave-surface is divided into "half-wave zones" (see text-books on Optics). These zones are such that their resultant effects at some distant point P are alternately in opposite directions (being  $\lambda/2$  different in path length measured from P). Two successive zones therefore neutralize each other's effects at P.

Plane-Waves of Sound Passing a Straight Edge.—Employing the Huyghens-Fresnel principle the distribution of sound beyond the edge of a totally reflecting wall may be determined. Outside the geometrical shadow there is a fluctuation of intensity which settles down, after a few oscillations, to the normal value in the absence of the wall. Inside the geometrical shadow the intensity steadily falls off from one quarter its normal value at the edge to zero at some distance inside the geometrical shadow. The relatively feeble diffracted sound behind the wall is easily observed by the ear if the incident sound-wave is of audible frequency and of moderate intensity. With high pitched sounds (e.g., from a Galton's whistle or a high frequency diaphragm excited electro-magnetically) and a sensitive receiver the variations of intensity at a diffracting edge can be observed experimentally. A sensitive flame may be used as the indicator of sound intensity or alternatively, if the sound is in the audible range, a stethoscope tube with a small funnel opening may be used to listen directly. The gradual fading away of sound within the geometrical shadow is a common observation at all frequencies.

Circular Obstacle. Scattering of Sound-Waves.—Constructing Fresnel zones outside the edge of a circular obstacle, it will be found that the total effect at a point on the axis is equal to half

were interposed This is true whatever the size of the disc relative to the wave-length of the sound. Immediately surrounding the central spot there is a ring of almost complete silence and beyond that a further increase of intensity, and so on. These effects can be demonstrated in the manner suggested above for a straight edge. This case is analogous to that of the bright spot at the central point of the optical shadow of a circular discone of the "classical proofs" of the wave theory of light. It finds an important application in the directional reception of sound (sec p. 28).

Scattering by Small Obstacles .- Rayleigh has shown that the intensity of the sound scattered in all directions by an obstacle is directly proportional to the volume of the obstacle and inversely proportional to the fourth power of the wave-length of the sound. This law also applies to the scattering of light and is used to explain the blue colour of the sky. We have already referred to an illustration in sound, viz., harmonic echoes, in which the higher constituents of a complex sound are scattered more readily than the fundamental, with the result that the scattered or diffusely reflected sound appears raised in pitch by one or more octaves.

Circular Aperture.-The transmission of sound through a circular opening in an extended wall has already been considered in the analogous case of sound radiation from a piston (such as a Langevin quartz oscillator), the sound distribution beyond the opening consisting of a primary beam and a number of secondaries separated by silent regions. An experiment showing the antagonism between the parts of a wave corresponding to the first and second Fresnel zones is described by Rayleigh (Sound, Vol. II., p. 141). Sound-waves from a high pitched source fall on a screen with a circular opening of variable diameter. A sensitive flame is situated on the axis on the opposite side of the screen. The flame is unaffected by the sound which gets through a large opening, comprising two opposed Fresnel zones but flares violently when the area is reduced to one zone.

Zone Plates .- Let circles be drawn, on a plane reflector, with radii,  $r_1 r_2 r_3$ , etc., given by  $r_n^2 = n\lambda d$  where n = 1, 2, 3, etc., and d is the distance of the centre O from a point P on the axis normal to the reflector. The circles divide the surface of the reflector into Fresnel half-wave zones with respect to the point P. It will be seen that these annular zones are of equal area. If alternate zones are cut away, a plane sound-wave falling on the plate and passing through the annular openings will arrive in phase at P, resulting in a considerable increase of intensity at that point. A zone plate of this kind therefore acts like a convex lens of focal length  $\hat{O}P = f = r_n^2/n$ ,  $r_n$  being the radius of the *n*th zone and  $\lambda$  the wave-length of the sound. The focusing properties of such zone plates were demonstrated by Rayleigh by means of high pitched sounds and sensitive flames.

Diffraction Gratings. Reflection from Stepped or Corrugated Surfaces.—The diffraction grating, so familiar in optics, has its counterpart in sound. When sound-waves are reflected from a regular periodic structure, such as a row of palings or a corrugated surface, the reflected-waves may assist or neutralize each other in certain directions depending on the wave-length \( \lambda \) of the sound and the spacing d of the reflectors. The diffractedwaves have maxima in directions  $\theta$  given by  $\sin \theta = \pm n \lambda/d$  where n = 1, 2, 3, etc. When d is smaller than  $\lambda$  there are no diffracted waves and the incident beam is reflected in the ordinary way. Thus a row of palings or a rough wall reflects sounds of moderate pitch like a perfectly smooth surface, little or no sound being returned towards the source, except in the case of normal incidence. When the sound is high pitched, however, \u03b4 being less than d, it is thrown back in all directions reinforcing along certain lines and neutralizing in others. A regular row of palings may serve as a "reflection" or a "transmission" grating. W. Altberg (Ann. d. Physik, 23, 1907) demonstrated a diffraction grating of this nature by means of glass rods r cm. apart, using a concave reflector to produce plane-waves of sound incident on the grating. The sound was produced by means of a high

frequency electric spark emitting waves only a few millimetres in and falls in pitch once per revolution. The observed pitch of the length. A second concave mirror received the diffracted sound and brought it to a focus at a sensitive detector. The sound spectrum was obtained by rotation of the grating with respect to the source and receiver. Wave-lengths of the order 0.2 mm., corresponding to a frequency 1.5 million per second, were measured in this way.

Experimental Study of Wave Transmission .- Many of the "optical" characteristics of sound which we have mentioned may be studied on a laboratory scale by the following methods: (a) Spark Photography. The progress of a sound pulse may be observed either by the "Schlieren Method" (due to Topler 1867) or the "Shadow Method" (due to Dvořák 1880). In the latter case, the sound pulse is produced by an electric spark (the sound spark), followed by a second spark (the light spark, between magnesium electrodes) at a known short interval of time. The highly compressed region forming the envelope of the sound pulse casts a shadow, when illuminated by the light spark, on a screen or a photographic plate. A succession of photographs at varying time-intervals after production of the sound-spark indicates the progress of the sound-pulse. The various phenomena of reflection, refraction and diffraction have been demonstrated in this way (see for example, Foley and Souder, Phys. Rev., 35. 373. 1912). Photographs of this nature are shown in the Plate, figs. 1a to f. (b) Ripple Photography. Results of a similar character may be obtained more easily by means of the ripple tank. This method is based on the fact that impulsive ripples on the surface of a liquid, e.g., water or mercury in a small tank, bear a striking resemblance to impulsive soundwaves. The ripples are reflected, refracted and diffracted from objects placed in the liquid, as shown in the Plate, Fig. 12. The method was first used by Vincent (Phil. Mag., 43. 17. 1897) to demonstrate interference phenomena, but more recently it has received a wider application in the study of complex reflections occurring in models of buildings (see Article on Acoustics of Buildings; and Davis, Proc. Phys. Soc., 38, 234, 1926). (c) Bullet photography. The "bow" wave from a high speed bullet (see Plate I., fig. 2) has been utilised to demonstrate the reflection and diffraction of a sound-pulse. Thus in C. V. Boys photographs of a bullet in flight (Nature, 47. 415. 440. 1893) the pulse is seen to be reflected according to optical laws. Cranz (Handbuch der Physik, Vol. VIII, Geiger and Scheele) has photographed the track of a bullet passing between two parallel plates, and the multiple reflections of the bow-waves are beautifully shown. The method is not so convenient as the spark and ripple methods, but it possesses certain novel features.

Doppler's Principle.-Moving Sources and Receivers.-The pitch of a sound is liable to be modified when the source and receiver are in relative motion. Thus an observer approaching the source with velocity v will encounter more sound-waves per second than if he had remained at rest, the number of sound waves per second (the pitch of the note) being increased in the ratio (c+v)/c where c is the normal velocity of sound in the medium. Similarly when the observer is at rest and the source moving, the change of pitch will be in the ratio c/c±v according as the source is approaching or receding. The whistle of a locomotive is raised in pitch as it approaches, and falls in pitch as it recedes from an observer. The principle of change of pitch by relative motion is due to Doppler, who first enunciated it in connection with the change of colour of certain stars moving in the line of sight of an observer. If the medium is also in motion (e.g., wind) with velocity w in the direction of the soundwave, the observed pitch N1 relative to the actual pitch N will be  $N^1/N = (c \pm w \pm v)/(c \pm w)$ . When v = 0,  $N^1 = N$  irrespective of the velocity of the medium. The latter velocity w only affects the ratio N1/N slightly when the source and observer are in relative motion also. The Doppler effect can be produced in the laboratory by the simple expedient of rotating a maintained source of sound at the end of a bar or cord. Preferably the source should be maintained in vibration by virtue of the rotation. The observer in the plane of rotation hears a note which rises

sound from an aeroplane may vary by 20% according to the speed and direction of flight.

Attenuation of Sound-Waves. Viscosity and Heat Conduction .- We have hitherto considered plane or spherical waves travelling through various media without loss of energy. Apart from other considerations it will be evident that energy loss must take place wherever there is relative motion between the various particles comprising the medium, such loss being due to ordinary viscous forces which tend to degrade the sound energy into heat. In addition to this viscous loss there must be energy loss due to thermal conduction and radiation consequent on the compression and rarefaction of the medium. If the compressions and rarefactions succeed each other with sufficient rapidity the process will be strictly adiabatic, that is, there will be no transfer of heat between compressed and rarefied regions or to the parts of the medium unaffected by the sound-wave. Sound-waves of small amplitude in air are propagated under almost perfectly adiabatic conditions. Otherwise, as Stokes proved in 1851, the sound would be rapidly stifled, which is contrary to experience. In the case of sounds of very large-amplitude however (an explosion impulse, or the sound-wave emerging from a very powerful source), it is conceivable that the large temperature fluctuations in each cycle of pressure may be such as to involve appreciable temperature losses due to conduction and radiation even in a very short time interval. This would result in a more rapid decrease of sound-energy with distance than the inverse square law requires, the effect becoming increasingly serious the lower the frequency and the greater the amplitude of the sound waves. With regard to energy loss due to viscosity, Maxwell pointed out that the factor involved is the "kinematic viscosity coefficient" v, which is equal to the ordinary "static" coefficient µ divided by the density  $\rho$ . Thus for air  $\nu=0.132$  and for water ν=0.013 at 10°C. The amplitude ξ of the progressive wave therefore diminishes exponentially on account of energy loss on the way. In the case of plane-waves we have

$$\xi = ae^{-x/l} \cos n(t - x/c)$$

where l is the distance travelled by the wave before the amplitude falls to 1/e of its initial value. In this expression  $l = (3c/8\pi^2\nu)\lambda^2$ , indicating a rapid increase of attenuation with diminishing wave-length  $\lambda$  (i.e., with increase of frequency). To include the losses due to heat conduction also Maxwell multiplied  $\nu$  in the above expression by 2.5, the effect being therefore equivalent to a marked increase (to  $v^{l}$ ) of kinematic viscosity. On the above grounds there is clearly a physical upper limit to the frequency of vibration which can be transmitted an appreciable distance1. Rayleigh (Vol. 11, p. 28) concludes that the effects of energy losses of the above nature are to be sought for in the damping of the vibration rather than in the altered velocity of propagation. It should be mentioned that changes of velocity with frequency have actually been observed by Pierce in air and CO2 and by Boyle and Taylor in water, although no such change could be detected by Lang in the case of steel bars.

With regard to attenuation there is ample evidence confirming the above theory which indicates a rapid decrease of range with increasing frequency. For example in air, for sound-waves of frequency 1000,  $\lambda = 33$  cms., we find l = 40 kilometres since  $v^1 = 2 \cdot 5v = 0 \cdot 33$  for air. The value of l at a frequency 100,000 is consequently 4 metres only. In sea water  $\nu = 0.013$  that is  $v^1 = 0.0325$ , and  $c = 1.5 \times 10^5$  cms./sec., whence  $l = 3.9 \times 10^4$  kilometres at a frequency of 1000 ( $\lambda=150$  cms.), and l=3.9 kilometres at a frequency of 100,000 ( $\lambda = 1.5$  cms.). It is thus evident the attenuation of sound-waves in sea water due to viscosity and heat losses is almost negligible compared with the attenuation at corresponding frequencies in air. This accounts to some extent for the relatively large ranges of transmission observed under the sea compared with those in air for the same amount of sound energy at the source. A small charge (9 oz.) of guncotton ex-

<sup>1</sup>G. W. Pierce has shown experimentally that CO<sub>2</sub> becomes opapic to sound-waves at a frequency of 2×105 p.p.s.

ploded under water can be detected (and recorded by an Einthoven galvanometer) at 40 miles (see Wood and Browne, Phys. Soc. Proc., 1923). It is extremely improbable that such a range could be obtained in air. This comparison is of course only of a rough nature, for the wave form and the initial "amplitudes" would not be the same in the two cases. There is ample evidence to show, however, that the attenuation of bell sounds and other noises under water is less than in air. On account of other factors (nature of sound sources, homogeneity of medium, etc.) a strict comparison is somewhat difficult. Attenuation by scattering in a heterogeneous medium may be a serious factor in regard to loss of range in signalling by sound-waves. Tyndall found that a homogeneous atmosphere, clear or uniformly foggy, transmitted a sound signal to far greater distances than a "patchy" atmosphere containing masses of air at different temperatures, wind eddies, etc. Similarly when sound travels through water it may be seriously interrupted if it meets with a mass of bubbles. The sound of a ship's propeller does not pass very well through the bubbly water in the wake. Air bubbles in the sea may therefore be a serious cause of attenuation, the effects of viscosity and heat conduction being relatively small.

Sound Absorption in Narrow Tubes and Cavities. Porous Bodies.—When sound-waves fall on certain bodies which may be regarded as a mixture of solid and gas, e.g., cork or felt, it is found that a large proportion of the incident energy is absorbed due to viscosity and heat conduction. The influence of these factors is enormously increased on account of the large surface of solid matter in contact with the vibrating gas particles. Viscous forces are increased at the surface of the solid, and the latter serves also as an effective means of reducing the temperature fluctuations in the compressed gas, i.e., the compressions and rarefactions are no longer adiabatic. Rayleigh has shown theoretically (Sound, Vol. II, p. 331) that the attenuation of sound-waves in a narrow tube of circular section is proportional to the square root of kinematic viscosity p<sup>1</sup>, and the frequency N, and inversely proportional to the radius of the tube. Porous materials like felt, wool, cork, etc., are effective sound absorbers, and are used to reduce reverberations in auditoriums.

#### RECEPTION OF SOUND

The manner in which sound-energy is abstracted from the medium carrying the sound-waves is dependent on a wide variety of circumstances and each case must be treated accordingly. In the first place the choice of a receiver must depend on the medium of transmission-a receiver suitable for air being generally quite unsuitable under water or in a solid medium. Again the selection of a receiver will depend on the frequency and wave form of the vibration-sounds of frequencies 500 or 50,000, or a single explosion impulse, requiring entirely different treatment. If the sound-wave is employed in long-range signalling it is important that the receiver should be efficiently designed and tuned to the incoming sound, in order to obtain maximum response to weak signals. Distortion of wave-form in this case may be of secondary importance. On the other hand, if it is required to obtain a faithful record or reproduction of the sound-wave, energy considerations are relatively unimportant whereas an accurate reproduction of the wave-form is vital. In this connection we have to distinguish between resonant and non-resonant receivers. As a general rule a resonant receiver is employed where maximum sensitivity and efficiency are required, whilst a non-resonant receiver is used for faithful recording or reproduction of the sound.

All forms of sound-receivers involve the introduction of some obstacle into the path of the sound-waves, this obstacle either partaking of, or otherwise influencing, the motion of the particles of the medium, or responding in some way to the pressure variations on its surface. Energy may be lost due to reflection and readiation from this obstacle, but in a good receiver a moderate amount of sound-energy is transferred from the medium and converted into a form convenient for observation. It is often desirable to trensform the mechanical vibrations of the medium

into another type of vibration or into some other form of energy. For example, longitudinal sound-waves passing through the air from the mouth of a speaker fall on the diaphragm of a telephone transmitter which is set into transverse vibration. This transverse vibration controls electrical energy which is transmitted to a distant diaphragm receiver and reconverted into mechanical energy in a form suitable for transmission to the ear. Many well known forms of sound-recording apparatus (e.g., Webster's Phonometer, Millar's Phonedeik, and the Hilger Audiometer) employ a diaphragm receiver with some optical means of indicating and recording the transverse vibrations. Other forms, exemplified by magnetophones, microphones, piezo-electric receivers, condenser microphones, etc., involve the conversion of mechanical into electrical energy. Sound-vibrations may also be observed by means of such devices as optical interferometry and sound shadow photography or by means of manometric and sensitive flames. Metrical forms of receiver such as the Rayleigh disc and the sound-radiometer (measuring radiation pressure of sound-waves) form another class, which might also include the various "phonometers," the hot-wire microphone, and piezoelectric receivers. The amplification of received sounds by mechanical devices, "mechanical transformers," mirrors, trumpets and resonators, or by electrical means, microphone and valve amplifiers, must also be considered. In certain cases special devices are required, as in sound-reception under water (hydrophones) or in the detection of sounds travelling through the ground (geophones). The above remarks will be sufficient to show the difficulty of attempting a comprehensive classification of soundreceivers. In what follows we shall deal with the more important types, some of which have already been mentioned.

The Ear .- Sensitivity and Audible Limits .- By far the most important and most universal receiver of sound is the ear. This 'organ of hearing" has a marvellous range of frequency and sensitivity; it can perceive vibrations of frequency varying from 20 to 30,000 cycles/sec., and can detect a sound of amplitude less than 10-8 cm. whilst it is not destroyed by a vibration having an amplitude a million times as great. The ear with its associated nerve endings has also remarkable powers of analysis. It can distinguish one complex sound from another and can ' intelligently" to a number of different sounds at the same time. For a complete description of the complicated structure of the ear, reference should be made to text books of physiology or anatomy. Briefly, it consists of a device which brings the waves of sound to act on a terminal expansion of the auditory nerve. This device is divided anatomically into three parts, the external ear with the auditory meatus, the tympanum and the internal ear. The external ear in the case of the lower animals is very movable, presumably to assist in sound-location. This function in man is rudimentary so that he can hear almost normally with his ears cut off. The external ear is separated from the tympanum by the "drum" of the ear or membrane tympani, which is set in vibration when sound-waves fall upon it. These vibrations are transmitted with diminishing amplitude but increased pressure by a chain of bones (malleus, incus and stapes) acting as a system of levers, to the fluid (perilymph) in the internal ear. The vibrations travel through the perilymph from the vestibule and the 'oval window" up the turns of the cochlea and ultimately to the basilar membrane thus affecting the haircells and the ends of the auditory nerve. Many theories, notably the resonance Theory of Helmholtz, have been proposed to explain the function of the various parts of the ear, in particular the cochlea and the basilar membrane (with the "rods of Corti" and the haircells), but none appears to be really satisfactory. It is certain, however, that the more highly developed the cochlea the more perfect is the hearing of an animal. This is shown in birds and mammals which have a far more perfect cochlea than is found in reptiles and fishes.

Sensitivity of the Ear to Intensity and Frequency Variation.— The relation between sensation (loudness) and stimulus (intensity) applicable to all sensations, is generally expressed by Weber's law—"The increase of stimulus necessary to produce the minithat is.

mum perceptible increase of sensation is proportional to the a sound proceeding from the right or the left is readily determined pre-existing stimulus." From this law Fechner derived the relation  $S=k\log E$  or  $\partial S/\partial E=k/E$ , where S is the magnitude of the sensation, E the intensity of the stimulus and k a constant. The "law" obviously approximates to the truth, for the sensitiveness of the ear  $\partial S/\partial E$  diminishes rapidly with increase of the total intensity E of the sound. Feeble sounds which are easily heard at night when E is small, cannot be distinguished from the general noise in the daytime when E is much greater. Wood and Young (Proc. Roy. Soc., A. 100, p. 264 and p. 266, 1921), in judging equality of two sounds of the same pitch, remark that under favourable conditions it was possible to distinguish a difference of intensity of 10%. A similar conclusion was reached by  $V_{\delta}$  O. Knudsen (*Phys. Rev.*, 21 Jan. 1923). Measuring the "intensity sensitivity" of the ear  $\delta E/E$  where  $\delta E$  is the least perceptible difference of energy and E the total energy of the tone, Knudsen found  $\delta E/E$  to be about 0-10 for moderate and large intensities E, but increased to the limiting value of unity as the intensity decreased to the threshold value Eo (the minimum energy of audibility). To include this region of very feeble intensities Knudsen proposed a modification of the Weber-Fechner law, namely,  $\delta E/E = k + (1-k) (E_o/E)^n$  where k = 0.10app. and n varies somewhat with frequency, being 1.65 for 200 cycles/sec. and 1.05 for 1,000 cycles/sec., nevertheless at the same loudness level e.g.,  $10^4 E_0$ ,  $\delta E/E$  is nearly independent of frequency. More recently R. R. Reisz (*Phys. Rev.*, 31, May, 1928) has found that  $\delta E/E$  lies between 0.05 and 0.15 according to frequency. He found also that  $\delta E/E$  is a minimum at 2,500 p.p.s.—this minimum being more sharply defined at the smaller sound-intensities. This frequency corresponds to the region of greatest absolute sensitivity of the ear. Fig. 12 indicates the range of the average human ear with regard to both intensity and frequency. The upper curve gives the sound-pressures (root mean square) which produce a sensation of feeling, and serves as a practical upper limit to the range of auditory sensation (Wegel, Bell System. Tech. Journ., 1, Nov. 1922) whilst the lower curve indicates the pressures at the threshold of audibility. It will be seen that the ear is most sensitive in the region of frequency 500 to 5,000 p.p.sec. The range of intensity (proportional to square of pressure) appreciated by the ear in this range is of the order The smallest detectable pressure-amplitude is of the order 10-3 dyne/cm.2, i.e., 10-9 of atmospheric pressure, corresponding to a displacement-amplitude of the order of 10-9 cm. Knudsen, Fletcher and Reisz independently conclude that near a frequency of 2,000 the ear can distinguish, under favourable conditions, from 300 to 400 gradations of loudness between the threshold of audibility and the threshold of feeling (a painful intensity 1012 times as great)—each step being recognisable by the ear as just perceptibly louder

than the one before it. Audible Limits of Frequency.-The lower and upper limits of frequency for tones audible to the human ear vary according to different observers. A very good average range of frequency may be taken as 20 to

20,000 cycles/sec. Very high

CM<sup>2</sup> 10000 £ 100

and very low pitched sounds of great intensity are felt rather than heard. The ear loses its power to discriminate variations of pitch at very high frequency. The frequency range employed in music extends from about 40 to 4,000 cycles/sec. When two notes within the range 500 to 4,000 cycles/sec. are sounded alternately, the ear can detect a difference of frequency of about 1 in 300. When the two notes are sounded together the discrimination is greatly improved—a frequency difference of one in 20,000 being readily discernible by "beats" (see p. 6). Kohlrausch demonstrated experimentally that the sensation of pitch may be excited even with so few as two vibrations.

Perception of Direction. Binaural Audition. - The direction of 21---B

with fair accuracy, but there is little difference observable between a sound approaching from behind or ahead. For high pitched sounds of short wave-length these directional effects might be explained by the difference of intensity of the sound reaching the two ears, since the head acts to some extent as a screen to the ear which is more remote from the source of sound. When the wave-length of the sound exceeds the perimeter of the head, however, the intensity difference must be very slight and we must look for another explanation of the directional effect. Rayleigh (Sound, Vol. II., p. 440) who has examined this question carefully, arrived at the conclusion that the perception of direction is dependent on the relative phase of the sounds as they reach the two ears, a small difference of phase being sufficient to indicate the required direction. He found that if the same tone be led by different paths to the two ears, the sound could be made to appear to come from the right or the left at will, by adjusting the path-lengths and consequently the relative phase. The origin of the sound was always attributed to that side on which the phase is in advance (by less than half a period). No explanation of this effect has yet been given.

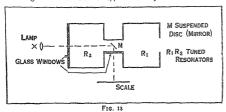

Pressure of Sound-Waves .- Radiometers .- Sound-waves, like light-waves, exert a slight pressure on any surface upon which they fall; and radiometers for measuring sound-intensity have been constructed on this principle. Rayleigh (Phil. Mag., 10, 1905) has determined this pressure on theoretical grounds, but a more simple treatment due to Larmor will suffice here. Planewaves are incident on a perfectly reflecting wall free to move, the wall being pushed with velocity v to meet the advancing sound-waves of velocity c and mean energy density E (see p. 28). The total energy density in front of the wall, if stationary, would be 2E due to the incident and reflected trains of waves. The length of the wave-train incident per second on the advancing wall is (c+v) this being compressed during transmission into a length (c-v) due to the approach of the wall. The energy density in the reflected-wave is therefore increased in the ratio

$$(E+\delta E)/E = (c+v)/(c-v) = 1 + 2v/c,$$
  
$$\delta E = E \cdot 2v/c.$$

The increase in the total energy in the region of length c in front of the moving wall is consequently  $c \cdot \delta E$ , and this must inevitably be due to the work done by the wall in compressing the radiation. If P is the radiation pressure, the work done by the wall per second is Pv, whence  $Pv = c \cdot \delta E = E \cdot 2v$ , that is, P = 2E, the mean radiation pressure being equal to the energy density in the medium in front of the wall. If the wall is a perfect absorber there will be no reflected-wave and P = E. Now the intensity of the sound is equal to the energy density × the wave-velocity c (see page 22). Provided therefore that the radiation pressure can be measured. and the reflection characteristics of the wall can be determined, we have here an absolute method of measuring sound-intensity. Radiometers for measuring the intensity of high frequency soundwaves under water have been constructed on the above principle by Langevin, Wills, Boyle and others. Boyle (Proc. Roy, Soc., Canada, 1925) constructed torsion pendulums for use with high frequency quartz oscillators under water. The pressure of the "ultra sonic" radiation on the pendulum vane causes a deflection which is reduced to zero by a torsion head. This gives a measure of the twisting moment and consequently the radiation pressure. Comparative measurements with such radiometers confirm the theoretical deduction that the radiation pressure is proportional to the energy density. All absolute measurements of radiation pressure must, of course, make allowance for diffraction at the edge of the reflecting vane. Using the radiometer method, Boyle measured the energy output of high frequency quartz oscillators and the reflection and transmission coefficients of various materials under water. Torsion radiometers have similarly been used to measure sound-intensity in air (Altherg, Ann. d. Phys., 11, 1903). They are only of value, however, in cases where the sound-intensity is very great.

Rayleigh Disc.—A device which is often used in sound-in-

tensity measurements is due to Rayleigh (Sound, Vol. II., p. 44). A delicately suspended disc (a small mirror about  $\frac{1}{2}$ -in. diameter) will tend to face a stream of air (or other medium) flowing past it, whether the flow be direct or alternating. The torque M on the disc tending to diminish  $\theta$ , the angle which the normal of the disc makes with the stream, is given by  $M = \frac{4}{3} \cdot \rho a^{2} \rho^{2} \sin 2\theta$ , "a" being the radius of the disc,  $\rho$  the density of the medium and

v the velocity of the stream. If the stream be alternating instead of steady, it is only necessary to employ the mean value of v2. The maximum torque is obtained when  $\theta = 45^{\circ}$ . A light galvanômeter mirror suspended on a fine quartz fibre provides a very sensitive arrangement, particularly when used inside a double resonator (see fig. 13) tuned to the frequency of the sound it is desired to measure. When accurately tuned to the sound falling upon the open end of the resonator R, the instrument can be used to compare the intensities of sounds of the same frequency. The sensitiveness is comparable with that of the ear. The deflections, if small, are proportional to the square of the particle velocity in the undisturbed field. It is important that the diameter of the disc should be small compared with the wave-length of the incident sound. As the double resonator and disc system is very sharply tuned, a large number of instruments would be required to cover a moderate range of frequency and intensity. A disc mounted in the mouth of a single resonator of continuously variable tuning is more generally useful, but is less

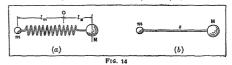

Resonant Receivers .- When the incoming sound-waves have a predominant frequency it is clearly advantageous to "tune" the receiver to obtain maximum sensitivity. The tuning of a receiver, e.g., an air cavity or a diaphragm is similar to the tuning of a sound transmitter. In many electrical cases the same device may serve either as a transmitter or a receiver, e.g., a telephone earpiece (magnetophone), a Fessenden electro-magnetic oscillator or a piezo-electric oscillator. Under these circumstances it is possible for the tuning to be very exact. A resonant air cavity develops a relatively large amplitude of vibration at its mouth, this amplitude being considerably in excess of that in the surrounding medium. The sound-field near such a resonator is affected by its behaviour as a secondary source, the energy which the resonator emits being drained from the other parts of the sound-field. It can be shown that the area of wave-front from which energy is extracted (and re-radiated) by a small resonator is  $\lambda^2/\pi$  where  $\lambda$  is the wave-length of the incident sound to which it is tuned. This area may be considerably greater than the area s of the resonator, the energy amplification being  $\lambda^2/\pi s$ . In actual resonators, however, only a part of this energy is reradiated, the remainder being absorbed. The latter portion is partly dissipated in viscous damping and partly converted into a useful form, i.e., is utilised in operating a detector, such as a microphone, or a magneto-phone, or in deflecting a mirror. The efficiency of the receiver is dependent on the proportion of the total energy which is usefully absorbed. Absorption of energy involves damping. The receiver is inefficient if it is underdamped, little or no energy being absorbed, or if it is over-damped, too much or all the energy being absorbed. If the receiver is underdamped it re-radiates too large a proportion of the received energy back into the medium. Overdamping reduces the sharpness of resonance and consequently reduces the area from which

energy is obtained, the main advantage of tuning being lost. The most efficient receiver lies between these extremes, i.e., the energy absorbed is equal to the energy re-radiated. In other words, in an efficient tuned receiver the damping due to the medium must be equal to the internal damping in the receiver. It is of course, equally important that the internal damping must be useful damping, i.e., the absorbed energy must be used efficiently. Thus if the receiver is electro-magnetic (a telephone receiver) it is important that the ratio of motional impedance (measured electrically) to total electrical impedance should be as great as possible. A solid resonator such as a tuned metal diaphragm in air is necessarily inefficient, for a large proportion of the incident energy is reflected or scattered from its surface as from a rigid obstacle. The energy re-radiated to the medium due to the vibration of the diaphragm is extremely small.

Mechanical Transformers.-It is sometimes desirable to convert an oscillation of large displacement and low pressure to one of small displacement and high pressure; a mechanical process analogous to the electrical transformation of a large alternating current at low voltage to a small current at high voltage. Hahneman (Inst. Radio Eng. Proc., II., Feb. 1923) has employed this principle in the design of sound-transmitters and receivers for use under water. As a rule, in such apparatus, one part of a vibrating system is actuated in air whilst another, coupled to it, vibrates in contact with water. In transferring vibratory pressure from air to water a "step-up" pressure transformer is required, and conversely. For this purpose Hahneman employs a mechanical lever of a novel type, the ordinary pivoted lever and link system being useless at even moderate frequencies. He also considers it desirable, as far as possible, to separate the mass and spring factors of the vibrating system, like a weight on a spring, rather than a combined mass and spring as in the prong of a tuning fork. The lever principle is as follows: Two masses m and M are connected as in fig. 14a by a spring of stiffness At resonance, neglecting energy radiated, the system will vibrate about its centre of gravity, the amplitudes a and A of m and M being inversely proportional to the masses, i.e., a/A =M/m. The spring will be undisplaced at the centre of gravity of the system, i.e., at some point O such that  $l_m/l_M = M/m = a/A$ . The natural frequency of the two parts on opposite sides of O is

$$N = \frac{1}{2\pi} \sqrt{s \left( \frac{1}{M} + \frac{1}{m} \right)}$$

In applying this principle to under-water sound transmitters, Hahneman replaces the diagrammatic helical spring by an elastic rod or tube, as in fig. 14b, which combined with the loads m and M tunes to the required frequency. The masses may be pistons or diaphragms suitable for electro-magnetic excitation and for the transmission of vibrations to the water (see fig. 3, plate, and Technical Applications: Sound-Signalling). S. T. Williams (Journ. Franklin Inst., Oct. 1946) refers to the

use of mechanical "transformers" in the design of a gramophone sound-box.

Diaphragm Receivers.—Unless special precautions are taken to ensure sufficient damping, the diaphragms of microphone transmitters and electro-magnetic receivers used in telephony will have marked resonant frequencies at which they are abnormally sensitive. For speech reception such resonances are undesirable. When maximum sensitiveness is required at one particular frequency it is a great advantage, however, to use a diaphragm tuned to that frequency. Tuned diaphragms with

. ¹ The "mechanical advantage," "velocity ratio" and "mechanical efficiency" of this alternating lever are analogous to those for static levers. either microphone or magnetophone (electro-magnetic) attachments have been used extensively in under-water signalling beamb has shown theoretically that for diaphragms having the same frequency in water the amplitude at resonance is inversely proportional to the area of the diaphragm. When an additional damping factor, such as a granular microphone, is introduced there is a "best size" of diaphragm, increasing with increase of the added damping. (See Powell, Phys. Soc. Proc., Feb. 1925.)

Electro-magnetic Receivers .- The vibrations of a diaphragm may be employed to excite currents in an electrical circuit embracing or lying in a magnetic field. The iron diaphragm of a telephone earpiece by its vibrations varies the magnetic flux passing through a coil and consequently induces alternating currents of the same frequency as the sound vibrations falling on the diaphragm. Similar results are obtained when an iron reed clamped at one end is set into vibration by sound-waves falling on a stiff cone attached to the free end of the reed. In an alternative form the diaphragm or reed, which now may be of nonmagnetic material, is attached rigidly to an annular coil of wire which lies in a strong magnetic field. Vibrations of the diaphragm and coil induce currents in the latter of the same frequency as the sound-waves. Telephone, microphone, and loud speaker movements are constructed on these principles. Such instruments can also be used to generate sound-waves by supplying the coil with alternating current of the required frequency. Diaphragm and reed receivers have usually marked resonant frequencies, the sharpness of resonance increasing with the load attached to the diaphragm (see p. 8). They may if required be used as "non-resonant" receivers, provided their natural resonances are reduced by damping or are far removed in frequency from that of the sound it is desired to receive. The efficiency of electro-magnetic receivers is determined from observations of damping and motional impedance (see p. 9).

Resonant Air Cavity. Hot-Wire Microphone -One of the most sensitive and metrical forms of resonant receiver for sounds in air, is a Helmholtz resonator fitted with a hot-wire microphone. In the hands of Tucker and Paris (Phil. Trans., 221. 1921) this combination has proved of great value in its technical applications and as a laboratory instrument for sound-measurement. It consists essentially of an electrically heated grid of fine platinum wire (0.0006 cm. diameter) placed in the neck of a Helmholtz resonator, or in the second neck of a "double-resonator" such as that shown in fig. 13. The oscillating air currents in the neck at resonance cool the hot grid, the extent of this cooling being measured (by a Wheatstone's bridge) as a change of electrical resistance. This resistance-change is a measure of the intensity of the sound. The instrument is calibrated by observing the cooling produced by steady air streams of known velocity. The sensitivity increases with increase of heating current. The tuning of the microphone and resonator is fairly sharp; in a typical example the response fell to one tenth of its maximum by "detuning" 7%, i.e.,  $n/p = 1 \pm 0.07$ . In common with other forms of Helmholtz resonator receivers, therefore, a series of instruments is required to cover a moderate range of frequency. The hot wire-microphone increases in sensitiveness towards the lower frequencies (say 100 per second); its upper limit being about 500 to 1,000 cycles/sec. The device has proved extremely useful in measurements of intensity and distribution of sound, particularly for testing trumpets, lenses, mirrors and other sound-concentrating devices and also for investigating the reflection and diffraction of sound-waves generally. Used in connection with resonators of very low frequency the hot-wire microphone proved of great value during the war in detecting and locating the positions of enemy guns. (See p. 22.)

Non-Resonant Receivers.—The ideal non-resonant receiver, equally sensitive at all frequencies, is not known. The best approximations aim at uniform sensitivity over a limited range of frequency—the better the receiver the more extended the range. Non-resonant receivers are, as a general rule, considerably less sensitive than the resonant type at a particular frequency but have a good average sensitivity over a wide range.

A good example for use in air, is Wente's condenser microphone (see Microphone) which employs a tightly stretched diaphragm of high natural frequency and a considerable amount of airdamping. Piezo-electric receivers are perhaps the best examples of the non-resonant type, for their natural frequencies are always very high (104 to 108). Rochelle salt, quartz and tourmaline suitably mounted give electrical effects which are an extremely faithful counterpart of the incident sound vibrations, over the whole sonic and a considerable region in the super-sonic range of frequencies. As Boyle, Langevin and others have shown, however, such receivers are most suitable for use in a medium like water. In air they are extremely insensitive, although Nicholson has obtained fairly good results with Rochelle salt receivers (see also p. 12). A multi-resonant receiver with a number of fairly flat overlapping resonance peaks, due to the various components which make up the receiver, could be designed to have a fairly uniform high sensitivity over a wide frequency range. The principle has been applied with success to gramophone recorders and reproducers (see p. 34). (See GRAMOPHONE)

Sensitive Flames are very convenient detectors of high frequency sounds in air. A long narrow gas flame, issuing from a "pinhole" orfice and adjusted to the point of flaring, becomes unstable, flares and shortens when high pitched sounds fall upon it. The action of such flames and sensitive jets of gas is discussed in Tyndall's and Rayleigh's Sound. The flame is commonly used to demonstrate the presence of nodes and antinodes in stationary-waves of high frequency, and to indicate the position of the sound focus of a concave reflector.

Under-Water Receivers. Hydrophones .- During recent years rapid progress has been made in sound-signalling under water, and the allied navigational problems of sound-ranging, echo-depth-sounding, submarine detection, etc. The earliest and most simple of all subaqueous receivers was known as the "Broca" tube which consisted of a long metal tube with a thin metal capsule fitted with a diaphragm stretched over the end. A similar, but less resonant, device employs a thick-walled rubber bulb in place of the diaphragm. The arrangement is fairly sensitive but is very inconvenient in use-observation at a distant point (on a ship, or at a shore station) being almost impossible. Electrical devices have replaced such tubes, both on the grounds of sensitiveness and convenience. Microphonic and electro-magnetic devices, attached to diaphragms and enclosed in watertight cavities have proved very satisfactory. Such subaqueous soundreceivers are generally known as hydrophones. Generally speaking, the diaphragms for use under water are much more massive than those used in air, on grounds of strength, durability and efficiency. A microphone or magnetophone (an electro-magnetic device like a telephone earpiece) attached to a metal diaphragm and immersed in water forms a system which may have one or more resonant frequencies. Such a receiver is therefore suitable where sensitivity is more important than "faithfulness"—i.e., for reception of under-water signals of a definite frequency, a suitably tuned diaphragm and microphone are desirable. paratively non-resonant receivers have been constructed of thick rubber—the sensitivity being correspondingly low—these being found valuable in discriminating between various types of ships' noises under water. Receivers of the diaphragm type are essentially pressure receivers. Another type of receiver known as the "light body" displacement receiver (see Wood and Young, Proc. Roy. Soc., 100, 1921) is essentially responsive to displacement or velocity of the water particles and is relatively insensitive to pressure. The two types may be compared with voltmeters and ammeters as electrical pressure and current measuring devices (see Drysdale in Mechanical Properties of Fluids, p. 293. See also Bragg, World of Sound, pp. 161-177). Reference has already been made to the use of piezo-electric devices for production and reception of high frequency sounds under water (see p. 12).

Geophones.—A simple device first used to detect enemy tunnelling operations in the war, serves to detect sound pulses travelling through the ground. It consists essentially of a cylin-

drical wooden box of about 3 in. diameter and 2 in. deep, divided into three compartments by two mica discs. The space between the discs is filled with mercury, whilst the two air compartments are connected to the ears by stethoscope tubes. The "geophone" is laid on the ground and vibrations are detected by the relative motion of the box and the mercury. The air spaces are alternately expanded and compressed, the sound pulses being conveyed to the ears via the tubes. Two such instruments, one compartment of each connected to each ear, give a sense of direction as in binaural audition.

Directional Reception.—This may be regarded as the converse of directional transmission of sound which we have already considered (see p. 18). We have referred also to the directional properties of a vibrating diaphragm when free to radiate, or receive, waves on both sides (see p. 29), and to the perception of direction by a pair of ears (see p. 29). These principles have been developed both for air and under-water reception of sound.

Diaphragms.—A single diaphragm or membrane mounted in a heavy annular ring and carrying a microphone at its centre forms a bi-directional receiver. A section of such a receiver is shown in fig. 15 (a) with its "figure of 8" polar curve of sensitivity. The microphone is unaffected when the sound pressure falls symmetrically on both sides of the diaphragm, whilst the response is a maximum when the sound-waves fall broadside on the diaphragm. The mode of action is discussed by Wood and Young in a paper dealing with the Admiralty pattern of "Single Plate Direction Finder" for use under the sea (Proc. Roy. Soc., 100. 1921). A disc of tightly stretched parchment mounted on a ring, with a light "button" microphone at the centre, gives excellent results in air. By means of a suitable screen ("bias" or "baffle plate") on one side of such a diaphragm it is possible to obtain a unidirectional instrument having the polar curve of sensitivity shown in fig. 15 (b). This baffle plate, when used under water, consists of a compound hollow disc containing air and lead shot (or some other suitable damping material to prevent excessive vibration of the walls of the cavity). Its exact function is somewhat complicated, but no doubt it acts partly as a sound screen and partly as a phase-shifting device with respect to the sound vibrations reaching the diaphragm. See Plate, figure 5.

Binaural Receivers.—The principle of binaural listening expounded by Rayleigh has been extended to the use of artificial "ears" which can be made very sensitive to a given type of sound and can be arranged at any convenient distance apart or with any orientation with respect to the source of sound. The principle has been applied to aeroplane and to submarine location (see Mechanical Properties of Fluids—"Submarine Listening," Drysdale). For example if two similar receiving trumpets are connected by equal lengths of tube to each ear, the trumpets

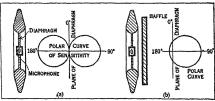

FIG. 15

being mounted a fixed distance apart on a rotatable platform, it is possible to locate a source of sound such as an aeroplane with considerable accuracy. The trumpets amplify the sound received by the ears and the directional accuracy is increased by increasing the distance apart of the trumpets. As the platform is swung round, the path-difference of the sound reaching the two ears diminishes on one side and then increases on the other, giving the impression of the sound crossing from one ear to the other. At the point of "cross-over", i.e., of binaural balance, the line joining the trumpets is at right angles to the direction of the

source. The same principle can be applied to a pair of underwater receivers. As an alternative to rotation of the line of the receivers it is often more convenient to vary the path-length to the two ears, the difference of path, relative to the distance apart of the receivers, being a measure of the "rotation" required to bring them symmetrical with respect to the source. This is known as the binaural compensator principle. The principle has been extended to multiple receivers, that is, to a considerable number of similar receivers equally spaced on a long base line. Instead of rotating the whole base line, a suitable rotary compensator is provided, the direction being indicated at the point of binaural balance. The directional properties of multiple receivers are the same as for corresponding multiple sources (see p. 31). In the case of electrical receivers the binaural method may be replaced by the Sum and Difference Method-the effects at the ear being due to the receivers assisting or opposing each other. The sound received by the ear is a maximum or a minimum respectively, when the normal to the line of the receivers is in the direction of the source of sound.

Receivers of Large Area .- Just as a directional source of sound is obtained by using a vibrating surface of large dimensions compared with a wave-length, so a receiver becomes increasingly directional as its dimensions increase. The piezo-electric quartz directional transmitter used by Boyle and Langevin serves equally well as a directional receiver. Similarly, large trumpets, mirrors and other focusing devices exhibit directional properties with increasing size or with increase in the pitch of the sound (i.e., with diminishing wave-length) Reference has already been made to the reflection which takes place at the open end of a cylindrical pipe or a trumpet acting as a sound receiver. The extent of this reflection diminishes, and the trumpet becomes a more efficient receiver, as the size of the opening increases, provided the length of the trumpet is always large. A parabolic mirror converges the sound energy towards a focus, but it must not be assumed that this is in any way an "optical focus," although it approximates more and more to it as the wave-length of the sound diminishes. A watch tick, the sharp crack of a pistol or an electric spark may be focused very effectively by a mirror of moderate dimensions. The increase of loudness due to curvature depends on the area of the reflecting surface, from which disturbances of uniform phase arrive, as compared with the area of the first Fresnel's zone of a plane reflector in the same position. If the "focal length" of the reflector is considerable and \(\lambda\) is not small, the first Fresnel zone is fairly large, therefore for a reflector of moderate dimensions there is little to be gained by making it concave.

Diffraction Disc Method.—On p. 26 reference was made to the fact that the sound intensity at a point on the axis of a circular obstacle placed normal to a beam of sound is as great as if the obstacle were not present, i.e., the sound "shadow" of the disc has, to quote the optical analogy, a bright spot at the centre. A microphone, tuned to the frequency of the incident sound, and placed at a suitable point on the axis of such a disc forms a very sensitive directional receiver, the response being a maximum when the sound is normal to the disc. Discs 20 feet or more in diameter have thus been used in combination with resonant hotwire microphones as an extremely accurate and sensitive means of locating distant sources of sound in air.

The location of sounds of an explosive nature by the use of a number of receivers on measured base lines is described in the section on Sound-Ranging (see p. 35).

Sound-Analysis and Recording.—It is sometimes desirable to determine the nature of a complex sound, more particularly in regard to the relative amplitudes and the frequencies of the component tones. The frequency analysis is relatively simple, but the amplitude measurement is much more difficult. There are numerous ways of determining the various frequencies present in a sound-wave, e.g., we have already referred to the use of Helmholtz resonators for this purpose. In frequency analysis it is more convenient to employ resonators of continuously variable frequency, e.g., by varying the volume of the resonator by

means of a sliding piston or a water column. Resonance in such a receiver may be detected in a number of ways, e.g., by ear, optical devices, Rayleigh disc, or some form of microphone, such as the hot-wire microphone. The use of resonators, whilst giving reliable information in regard to the frequencies of the tones present in the sound-wave gives only approximate information regarding the relative intensity of these tones.

Numerous instruments have been devised which are described as intensity or sound-energy-meters, many of which give indications in some way related to sound-intensity. In no case, however, is the device universally applicable to all frequencies and intensities. Many attempts have been made to record waveforms of sound by means of diaphragms and stretched membranes. The movements of a vibrating diaphragm excited by sound-waves have been recorded in various ways, mechanically, optically and electrically. Mechanical recording is exemplified in the gramophone, where a needle attached via a lever mechanism to the diaphragm traces the wave-form on a revolving disc or cylinder. (See GRAMOPHONE.) Optical methods have been very commonly used, e.g., in Kenelly's analysis of the motion of telephone diaphragms, in Webster's phonometer, in Millar's phonodeik and in the Hilger audiometer. In all these examples a small mirror reflects the vibrations of the diaphragm on to a moving photographic film. Electrical methods involve the use of a microphonic or electro-magnetic device which responds to the vibrations of the diaphragm, the corresponding electrical oscillations being recorded by means of some form of oscillograph, e.g., the Duddell strip, the Einthoven string or the cathode ray oscillograph (see Instruments, Electrical; see also Irwin, Oscillographs). The majority of such diaphragm receivers are subject to resonances at certain frequencies with the result that the record is a distortion of the actual wave-form, the distortion being greatest in the neighbourhood of the resonance frequencies of the instrument. The defect may be exaggerated or partially compensated by the use of a cone or trumpet to collect the sound and increase the amplitude of the diaphragm. Great care is necessary in the choice of a receiver, and recorder, for a particular type of sound, otherwise a number of factors may contribute to the distortion. Thus in electrical recording, distortion may be caused by resonance in the diaphragm, the microphone mounting, the trumpet or cone collector, the electrical circuit, and in the oscillograph. In addition to this, there may be distortion introduced solely on account of the dimensions of the receiver relative to the wave-lengths of the various components of the sound. As we have seen, a receiver which is large compared with a wave-length exhibits directional properties depending on the ratio  $\lambda/D$  (where D is the diameter of the receiver). One of the best non-resonant receivers developed during recent years is the stretched diaphragm condenser microphone of Wente (Phys. Rev. 10. 39. 1917). This was specially designed for sound-measure-

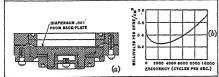

FIG. 16

ments and is used extensively in analysis and recording of waveforms of sounds lying within the frequency ranges of speech and music. The microphone, shown in diagram fig. 16a, consists essentially of a tightly stretched thin steel diaphragm (.oor in. thick) separated from a parallel back-plate by an air gap of o oor in. approximately. The diaphragm shown with its back-plate form an electrical condenser, the capacity of which is varied when vibration takes place. When 200 volts are applied through a fluctuating electromotive force. The variation of sensitiveness means for reproducing the original sound, using selenium or

of such a microphone with frequency is indicated in fig. 16 b. It will be seen that the output in milli volts (10-3 volt) per dyne/ cm.2 is fairly constant over a frequency range 500 to 5,000 cycles/ sec. The microphone is very insensitive when compared with other, more familiar, types (granular and electro-magnetic) but its freedom from resonance over a wide range of frequency renders it most valuable for purposes of sound analysis. The lack of sensitiveness can easily be remedied by the use of a "distortionless" valve-amplifier (resistance-capacity coupled valves). Crandall (Bell. Syst. Tech. Jour., 4. 1925, p. 587) employed Wente's condenser microphone in conjunction with such a valve amplifier to record speech sounds. A well designed amplifier will give practically constant amplification over the range of speech frequencies and will give an output proportional to input. The amplified e.m.f. is recorded by means of an oscillograph which must itself be non-resonant over the range of frequencies to be recorded. With certain limitations a high frequency Duddell strip well damped may serve the purpose, or alternatively an Einthoven oscillograph with a critically damped fibre of silvered quartz may be used. Perhaps the most perfect form of sound recording system is one proposed by Sir J. J. Thomson, namely a piezo-electric crystal receiver used in conjunction with a cathode ray oscillograph. Such a combination was used by Keys (Phil. Mag., Vol. 42, 1921) in recording the pressure-time curve of an explosion-wave under water. The piezo-electric receiver has a very high natural frequency and is consequently non-resonant over a very wide frequency-interval which includes the audible range. The cathode ray oscillograph (see A. B. Wood, Proc. Inst. Elect. Eng., Nov., 1925) is a perfect nonresonant recorder of electrical oscillations, having the same sensitivity at all frequencies from zero to the highest "radio" frequency. The combination may therefore be regarded as distortionless. The sensitivity for sounds of moderate intensity is, however, very small and amplification is necessary. The faithfulness of reproduction is ultimately dependent on limitations of the amplifier.

Measurement of the Amplitude of a Vibrating Body .-W. H. Bragg has described a very simple and ingenious method of measuring the amplitude of a vibrating surface (e.g., of a diaphragm). A small mass supported by a spring is brought into contact with the vibrating surface and the fixed end of the spring displaced through a distance A until there is no longer "chattering" between the mass and the diaphragm. At the point where chattering ceases, the maximum acceleration of the diaphragm is just equal to that of the mass attached to the spring. Thus if a and n and A and N represent the maximum amplitude and the frequency of the diaphragm and the spring respectively, we must have  $an^2 = AN^2$  or  $a = AN^2/n^2$ . sequently if N is very small compared with n, A will be very large compared with a, in this way yielding a large "magnifica-tion" of the amplitude to be measured. As an example, if n=1,000 p.p.s. N=1 p.p.s. and A=1 cm., then  $a=10^{-6}$  cm. The method permits of the measurement of very small amplitudes, the chattering being observed electrically. It is important of course to observe that the measuring device is sufficiently light so as not to interfere with the motion of the vibrating surface whose amplitude is required. Measurements of the amplitude of vibration of a diaphragm have also been made by making it one of the reflecting surfaces of a Michelson interferometer (Webster, Nat. Acad. Sci., 5, p. 179, 1919). The displacement of the interference fringes, photographed in vibration as a wavy line, gives a measure of the amplitude in terms of the wavelength of light. Such a diaphragm then forms a standard source of sound. Known amplitudes of vibration may also be obtained by applying measured alternating voltages to piezo-electric crystals, provided resonance-frequencies (usually extremely high) are avoided. Rankine has described (Proc. Phys. Soc., Aug. 1919, and Feb. 1920) a method of recording sound vibrations by means of variations in the intensity of a beam of light, the high resistance to the condenser, the vibration results in a resulting film, of varying transparency, forming a convenient other photoelectric cells. When a wave-form has been recorded by any of the methods indicated above, it may be analysed into a Fourier series (see p. 7) which gives the frequencies and relative amplitudes of the tones of which the sound is composed.

#### TECHNICAL APPLICATIONS

The past ten or fifteen years mark a period of considerable progress in the technical application of the principles of sound. It is proposed in what follows to deal with the more outstanding of these applications apart from those already mentioned in the foregoing sections. The exigencies of war stimulated the development of apparatus for detecting, identifying, and locating sounds at long ranges. Numerous forms of directional sound-receivers, sound-ranging and sound-signalling devices were realised and applied to urgent problems on land and sea. Since the war, the growth of radio-telephony and "broadcasting" has resulted in improved methods of reproducing sounds of audible frequency. The phenomena of piezo-electricity, discovered by Curie in 1880, have in the hands of Cady and others developed into a means of standardising mechanical and electrical frequencies over a range extending up to millions of vibrations per second. In this respect also improvements in tuning fork design have played an important part. A further application of piezo-electricity, initiated by Langevin and developed by Boyle, employs the supersonic oscillations of quartz in depth sounding at sea and in the echo detection of icebergs. At the other end of the frequency scale. Constantinesco has developed a system of power transmission through water-filled pipes, employing generators, motors, transformers and transmission lines closely analogous to the corresponding electrical devices. Such alternating mechanical systems are capable of dealing with large amounts of power in the form of low frequency pressure-waves. The elimination of objectionable resonance from gramophones and loud-speakers represents a marked degree of progress in the development of apparatus for reproducing speech and music. The study of the characteristics of speech and hearing, notably the work of the staff of the Bell Telephone Laboratory U.S.A., has greatly increased our knowledge of these subjects. The results have proved of great value in the improvement of telephone apparatus, microphones, electro-magnetic receivers, transmission lines, etc., and in the design of all forms of apparatus for recording or reproducing speech and music. In this connection also the introduction of the conception of acoustic impedance. as the analogue of electrical impedance, in dealing with complex acoustical systems has proved of great value. In a recent discourse before the Royal Aeronautical Society, Tucker has dealt with the problem of noise-reduction in aircraft, the deafening roar in the cabins of civil aircraft being a serious hindrance to commercial development. The general question of reduction of traffic noise is becoming increasingly insistent as an urgent practical problem still awaiting solution.

Reproduction of Sound .- The telephone (q.v.), the gramophone (q.v.) and the radio loud-speaker are among the most familiar types of reproducers of the sounds of speech and music. Any practicable device of this character for reproducing sound must necessarily have its limitations, for the faithful reproduction of even the simplest sounds is very difficult. As we have seen (p. 32), however, the ear is sufficiently accommodating to ignore fairly large defects in reproduction. Thus a 10% error in intensity, or possibly more than this, may pass unnoticed; the accuracy of intensity reproduction therefore need not be very great to conform with such a standard. Frequency reproduction, however, must be much more accurate to satisfy the ear, and it is indeed fortunate that the practical difficulties in this case are relatively small. Reproduction of sounds involves reception, and possibly transmission and amplification, as a preliminary. The process is well illustrated in the gramophone with either mechanical or electrical recording and reproduction. The recording system involves the direct mechanical action of sound-waves on a diaphragm, lever system, and engraving stylus, or alternatively on a system employing a microphone and a recorder

operated electro-magnetically. In reproduction the process takes place in the reverse order, some form of horn, cone or diaphragm being utilised to couple the vibrations of the sound-box or electrical "pick up" with the external body of air. The present practice in design is to regard the complex mechanical system, e.g., of a gramophone, as analogous to a corresponding electrical system. In this respect the analogy with electrical filter circuits, as stated by G. W. Stewart, has proved an extremely fruitful one. S. T. Williams and A. Whitaker have both applied this principle with considerable success in designing gramophone recorders and reproducers. By suitably choosing the inertia, stiffness and damping of the various elements of the sound-box and horn, a moderately good response-curve is obtained free from pronounced resonance within the speech-music range 150-4,000 p.p.sec. Electrical methods of recording and reproducing have recently yielded even better results. The desirable features in gramophones and loud-speakers are dealt with in a number of papers by various authorities in Proc. Inst. Electrical Engineers, Nov. 1923. The practical considerations are far too numerous to mention here but the essence of the problem of faithful reproduction lies in the avoidance of predominant resonances in the electrical and mechanical systems. This result may be achieved in some degree (a) by arranging that the natural frequencies of all elements of the system are far removed from any frequency it is desired to reproduce. (b) by the use of heavy damping, or (c) by making use of multiple resonance, i.e., arranging the various resonance peaks to overlap in such a way as to give a fairly uniform response. (See Rothwell, Nature, Feb. 24, 1923, and Porter, Phys. Soc., Feb. 1924.)

Mention has already been made of the recording of sounds on a film by means of light of variable intensity (Rankine, loc. cit p. 33). When a beam of light, after passing through such a film moving at the recording rate, falls on a sensitive cell (selenium, thalofide or photoelectric) the original sounds may be reproduced in a telephone or loud-speaker connected in circuit with the cell and a suitable amplifier. "Speaking films" have been produced successfully on this principle, the speech record being made on the edge of the film simultaneously with the cinema pictures. (See SELENIUM CELL.) Numerous other optical methods have been employed, with more or less success, to modulate a beam of light as a means of sound-reproduction, e.g., use has been made of the Kerr electro-optical and the Faraday magneto-optical effects, and of the luminous electric discharge in rarefiel gases.

Musical Instruments.—To deal adequately with the technical application of sound to the design and construction of musical instruments would require a very lengthy article in itself. Occasional references to such applications will be found above (section on Sources of Sound), but for detailed information the reader is referred to treatises such as The Dictionary of Applied Physics or Millar's Science of Musical Sounds.

The Acoustics of Buildings.—This subject is discussed in a separate article under that title.

Sound-Signalling.-In the section on sources of sound, reference has been made to various types of siren and the diaphone (p. 15) for producing powerful sounds in air, mainly for use in fog-signalling from light-houses and light-ships. Under the sea, large bells are used for a similar purpose. A more powerful under-water signalling device, due to Fessenden, employs a large diaphragm forced into resonant vibration under water. The apparatus consists essentially of a transformer, the secondary of which is free to move in a strong radial magnetic field. The primary is supplied with alternating current, and the resulting periodic motion of the secondary (a copper cylinder) is communicated to the submerged steel diaphragm which gives rise to sound waves in the water. The Fessenden oscillator is illustrated on the Plate, figure 4. The same device operates, conversely, as a receiver of sound-waves, these being converted into electrical oscillations by the vibration of the copper cylinder in the magnetic field, the induced currents in the primary coil being amplified and passed through telephones. Fessenden has used the apparatus to transmit signals through water to dis-

tances exceeding 30 miles and has even used it to transmit speech for a distance of half a mile. The oscillator has also been applied to detect icebergs and to take continuous depth soundings by echo methods (see below). In another form of oscillator, which is manufactured by the Signal Gesellschaft. Kiel, Hahneman has obtained powerful signals by means of a diaphragm excited in a different way. The diaphragm forms one member of a coupled system of two masses connected by a stiff spring (metal tubes). A powerful alternating current magnet causes periodic stretching of these tubes with corresponding vibrations of the diaphragm. A transmitter of this type weighing about 5 cwts. and having a diaphragm 18 inches diameter, gives a sound output of 300 to 400 watts, the mechanical efficiency being about 50% Reference to supersonic directional transmitters of the Langevin type, and to directional receivers, has already been made (see pp. 31 and 32 respectively).

Eche Depth Sounding .- Since the war considerable progress has been made in the development of new systems of sounding at sea. These new methods all employ, most appropriately, sound-waves as a means of measuring depths. The saving of time and labour is enormous and such methods are steadily replacing the old lead and wire systems which have survived so long. A sounding in 4,000 fathoms can be made in about 10 seconds by the new "echo" methods, whereas many hours labour arc involved to obtain a somewhat uncertain value by the old "wire" system. An additional advantage lies also in the fact that observations of depth can be made whilst the ship is in motion, up to speeds of 15 or 20 knots. The echo method involves the measurement of distance in terms of the time interval between the initiation of a sound impulse and the reception of an echo. This requires a knowledge of the velocity c of the sound waves in the medium, water or air; and depends on the fact that sound is reflected from the sea-bed in the same way that it is reflected in air from buildings and cliffs. The distance travelled by the wave in the time t is 2D, the depth D is therefore equal to c/2t. Various systems have been devised in America, France, Germany, and Great Britain, differing in the manner of producing and receiving the sound impulse and in the measurement of the time interval. In the Behm system, a small detonator is fired under water thereby operating a microphone and relay and setting a graduated disc in motion; the arrival of the echo stops the disc which is engraved in "depths." The angle through which the disc has revolved is a measure of the time interval t and consequently of the depth D. The system developed by the British Admiralty depends on the indirect measurement of the time interval. The transmitter consists essentially of a steel diaphragm which is struck a powerful blow by an electro-magnetic hammer. thereby emitting a heavily damped sound-wave of about 2,000 p.p.s. The receiver is au ordinary "button" carbon granule microphone mounted on a small diaphragm and enclosed in a watertight container. The transmitter and receiver are mounted in water-filled tanks fitted inside the ship's plates at points screened by the hull. A small motor drives two commutator switches at constant speed. One of these commutators actuates the hammer three times per second whilst the other short circuits a pair of brushes across the listening telephones except at one particular moment during which they can "listen." position of these brushes may be displaced by hand relative to the corresponding brushes in the transmitter circuit, so that a short time interval, proportional to the angular displacement of the brushes, separates the initial sound impulse and the moment when the telephones listen. Nothing is heard therefore unless this moment coincides with the moment of arrival of the echo. The angular displacement of the brushes measures the time interval (360° = 1 second). The dial attached to the rotatable telephone brushes is graduated in feet, or fathoms, and depths may be taken continuously whilst the ship is in motion. Two types of apparatus have been developed, (a) The shallow water set (described above), up to 150 fathoms, and (b) Oceanic depth apparatus, up to 4,000 fathoms or so. Both types are in regular service in numerous British and foreign commercial vessels and

in the survey ships of the British Navy. Fessenden (U.S.A.) has devised a depth sounding system similar to the above, using his "oscillator" for the purpose of generating the short sound impulses. He claims in addition to depth sounding, to have used the apparatus to detect icebergs at distances up to  $2\frac{1}{2}$  miles, a somewhat remarkable and surprising result, in view of the dimensions of icebergs, the wave-length of the sound (10 ft.approx.) employed, and the poor reflecting properties of ice under water. Boyle and Reid, using a Langevin directional quartz oscillator at supersonic frequencies could not detect an iceberg beyond 200 yards. The echo from ice was found to be very feeble compared with that from a rocky shore. The supersonic method has also been employed by Langevin and by Boyle in depth sounding; a good echo from the bed of the sea being easily distinguishable at considerable depths.

Sound-Ranging.-The location of hostile guns on land, and of submarine explosions at sea, constitutes one of the most important practical applications of sound during the war. Ordinary directional receiving devices such as those already considered are of little service when the sound consists of a sudden impulse or shock. The location of the explosion originating the impulse requires a special technique which is generally called soundranging. We shall deal first of all with the war-method or multiple-point sound-ranging. In this method three or more receivers are mounted at known positions on surveyed base lines. The spherical explosion wave WF passes over, say, four receivers, o, 1, 2, 3, in succession, the times of passage being recorded at instants t1 t2 t3 respectively. The construction shown in fig. 17 indicates in a simple manner how the explosion E is located. If we draw circles of radii ct1 ct2 and ct3 with centres at 1, 2, 3, respectively, c being the appropriate velocity of sound, then a circle WF which passes through the receiver o and is tangential to the three small circles will have the point of the explosion E at its centre.

The accurate mathematical method of determining E from the values h h and h depends on the fact that this point lies at the intersection of hyperbolae having the various receivers o, 1, 2, 3, as foci.

Army Sound-Ranging.—Six microphones were generally used, spaced along a base about 9,000 yards long and 4,000 yards behind the front line, a central recording station, to which the microphone leads were brought, being situated 5,000 or 6,000 yards from the front line. For hostile gun-ranging a special type of microphone, particularly sensitive to the low frequency disturbance of the sound of discharge of the gun, was devised. This microphone, known as the resonant hot-wire microphone, invented by Tucker, has already been described (see p. 31). The hot-wire

grid was mounted in the opening of a large Helmoltz resonator of about 16 litres capacity; the system responding only to very low frequency gun-sounds, whilst ignoring shell-wave (onde de choc), detonation of shell, and noises such as speech, traffic, or rifle fire. The resonance set up by a gun-sound produced cooling of the grid with consequent variation of the electrical current flowing through it. This current-change was photographically

recorded at the central station by means of an Einthoven string galvanometer fitted with six strings, one for each microphone. The resulting record, which was automatically developed and fixed, showed the six gun "signatures" on lines running parallel to the film. Across these lines, i.e., at right angles to the film, were a series of time marks every hundredth and tenth of a second, providing a direct means of measuring the time intervals with an accuracy of ooor second, if required (see the illustration on the Plate, fig. 6a). The record was started when a forward observer, or a "sentry" microphone, heard the gun, i.e., a few

seconds before the sound-wave reached the first receiver on the base. The measured time intervals were corrected for temperature and wind, which have a considerable influence on the velocity of sound (see p. 5). Variation of these factors with height results in troublesome refraction corrections, and under certain conditions of wind gradient, sound-ranging became impossible. The sound-ranging method could, under certain conditions, be employed to locate both an enemy gun and the answering shell-burst, in which case the comparative records eliminate uncertainties arising from atmospheric conditions.

Navy Sound-Ranging .- The method employed at sea during the war was based on the same principles, but the receivers were essentially different. Under water, the sound of an explosion was received on a steel diaphragm on which was mounted a sensitive granular microphone. The diaphragm formed the cover of a watertight case mounted on a large tripod which rested on the sea bed. Four or more of such "tripod hydrophones" were laid in accurately surveyed positions on a 12 mile base line. They were connected by means of cables to a six-stringed Einthoven galvanometer in the recording station on shore, the subsequent procedure to obtain photographic records of an explosion being essentially the same as outlined above. Specimen records are illustrated on the Plate, figure 6b. During the war, explosions of mines, depth charges and torpedoes could be located with great accuracy at distances of 50 or 60 miles from the base line of hydrophones. Since the war the method has been applied to the accurate location of buoys and light-vessels, a small charge being fired under water in the vicinity of the point to be surveyed. For such purposes it was necessary to know the velocity of sound in sea water at different temperatures and salinities, with great accuracy (see p. 20). As an alternative to the Einthoven photographic recorder system of measuring time intervals, A. B. Wood and J. M. Ford (see *Jour. Sci. Instr.*, Mar. 1924) have devised a "Phonic Chronometer." This consists essentially of an electromagnetically operated stop-watch with three sets of dials for measuring three independent time intervals. The speed of the chronometer is governed by a tuning fork and phonic motor giving an accuracy of 1 in 10,000. Time intervals are indicated directly on the dials to o-oor second. Special diaphragm shock receivers were designed for use with the chronometer, which was started and stopped as the explosion-wave passed the various receivers, the time intervals being read directly on the dials.

Radio-Acoustic Sound-Ranging.-This method which for obvious reasons could not be used in war time, was first proposed by Joly, and has recently been developed by A. B. Wood and H. E. Browne for the British Admiralty (*Proc. Phys. Soc.*, April 1923). It consists in the simultaneous emission of a "wireless" signal and an explosion impulse. The former travels with the velocity of light (186,000 miles/sec.) the latter with a velocity about 1 mile a second in water. If, therefore, one string of the Einthoven galvanometer on shore records the radio-signal whilst the others record the arrival of the explosion wave at the various hydrophones, we have a very simple and direct means of locating the explosion. The distance of the explosion from the hydrophones is given by ct1 ct2 ct3, etc., where c is the velocity of the sound in the sea and t1 t2 t3 are the time-intervals between the arrival of the wireless signal and the explosion-wave at the respective hydrophones. A g oz. charge of guncotton can be located in this way at 40 miles, whilst larger charges have been located up to 80 miles or more. At 80 miles the sound-wave through the sea arrives 12 minutes after the wireless signal which denotes the instant of firing the charge. The method permits of very great accuracy and has important applications in navigation and hydrographical survey. For navigational purposes great accuracy is sacrificed to speed, it being possible to give a ship in fog 40 miles away a positfon within a radius of half a mile in less than 10 minutes of receiving her request for a location. In hydrographical survey work the method has been used successfully to fix accurately the positions of buoys and light-vessels out of sight of land. The method is accurate in rough or foggy weather and at all seasons of the year. Various ingenious proposals have

been made to safeguard ships in fog, by application of radioacoustic methods (see Joly "Scientific Signalling and Safety at

acoustic methods (see Joly "Scientific Signalling and Safety at Sea," Phil. Mag, July 1918).

SAILIND THE the easternwoot of the straits giving entrance

SOUND, THE, the easternmost of the straits giving entrance to the Baltic Sea from the Cattegat, between the Danish island of Zealand and Sweden (Danish Oresund). Its extreme length from the promontory of Kullen to that of Falsterbo is 70 m. Its narrowest point is between Helsingör in Denmark and Helsingborg in Sweden, which are 3 m. apart. Its extreme width, 30 m., is where Kjoge Bay indents the coast of Zealand. Three islands lie in it-Hven, belonging to Sweden, and Saltholm and Amager, belonging to Denmark. The strait between Amager and Saltholm is called Drogden, and is used by large vessels passing through the Sound. The extreme depth of the Sound is about 14 fathoms. Navigation is open in winter, though three instances are recorded of the Sound being frozen over: in 1306, 1830 and 1836.

SOUNDING. The determination of the depth of the sea has been practised from very early times for purposes of navigation, but it is only since the introduction of submarine telegraphy that extensive efforts have been made to obtain a complete knowledge of the contour of the ocean-bed (see Ocean).

For depths over 20 fathoms sounding machines are often employed and wire has entirely superseded hemp gear. Its smooth surface and minute section, reducing friction to a minimum, give a rate of descent of about 100 fathoms per minute. Reeling in may be accomplished at nearly the same rate. Such soundings can be obtained in any weather short of a fresh gale. A sounding of 1,000 fathoms may be obtained in 25 minutes and 3,000 fathoms in 75 minutes. But beyond that depth, great caution is required, the time occupied is increased, and reeling in must be done very deliberately. A sounding of 5,269 fathoms was obtained near the island of Guam by the U.S. cable-surveying ship "Nero." Soundings at such depths may occupy a period of time lasting as long as five or six hours.

Lucas Machine.-Among the sounding machines in general use the Lucas carries nearly 6,000 fathoms of 20-gauge wire, and is fitted with two brakes-one a screw brake for holding the reel when required, the other an automatic brake for stopping the reel when the weights strike the bottom. A guider for winding the wire uniformly is also attached. After leaving the reel the wire passes over a registering wheel, the dial of which indicates the length of wire run out. Smaller machines are used in boats.

Sounding Rods and Sinkers .-- Under 1,000 fathoms a lead of 30 to 40 lb. weight can be recovered, and no detaching rod is necessary. For greater depths the "Baillie rod" is the best apparatus. It is a tube about 2 ft. long, having a rounded conical top, through which passes a movable steel rod. The lower part of the tube screws on and off, and contains a double flap valve to retain the bottom specimen. The sinkers, each 25 lb. in weight, conical in form, and pierced with a cylindrical hole through which the Baillie rod passes loosely, are slung by wire or cod line secured to a flat ring and passing over a projection on a movable rod to which the sounding wire is attached. The weight of the apparatus being taken by the sounding wire, the sinkers remain suspended; but on striking the bottom, the wire slackens, and the weight of the sinkers drags the movable rod down till the projection bears against the curved surface at the top of the rod. The wire sling is forced clear of the projection and the sinkers are slipped. In descending, the valves opening upwards, allow the

water to pass through freely; but on drawing up they are closed thus retaining the material with which the tube is filled. For depths under 2,000 fathoms two sinkers are sufficient. In deeper water a third cylindrical weight of 20 lb. should be put between them. It is important to interpose a hemp line, some 20 fathoms long, between the end of the wire (into which a thimble is seized) and the lead or rod. This prevents the wire from kinking on the lead striking the bottom.

Method of Sounding .- The machine is placed on a projecting platform on the forecastle. As the wire runs out the brake must be gradually screwed up, so as to increase the power in proportion to the amount of wire out. The regulating screw is marked for each 500 fathoms. In fairly smooth water the brake will at once act when the weight strikes the bottom and the reel stops. Under 3,000 fathoms one spring is sufficient, beyond that depth

two springs are required.

Handling the Ship .- Sounding from forward is preferable as it enables the ship to be handled with greater ease; in heavy weather when impossible to work on the forecastle, soundings may be obtained from a machine mounted over the stern. The ship's head must be kept in a direction which is the resultant of the direction and force of the wind and current; and this is arrived at by altering the course while sounding, point by point, until the wire can be kept up and down by moving the engines slowly ahead as necessary.

Observations of Temperature.-The temperature of the water is usually taken at intervals of 100 fathoms to a depth of 1,000 fathoms, and at closer intervals in the first 100 fathoms. If a second wire machine is available, the observations may be made from aft whilst the sounding is being taken forward. A 30-lb. sinker is attached to the end of the wire, and the registering thermometers are secured to the wire by the metal clips at the back of the cases, at the required intervals. To avoid heavy loss, no more than four thermometers should be on the wire at

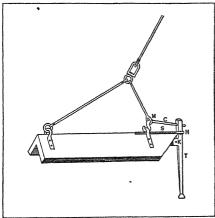

FIG. 1.-SUBMARINE SENTRY

one time. When sounding a thermometer is usually attached to the line a short distance above the lead.

Submarine Sentry.-The primary object of the machine called the "submarine sentry" is to supply an automatic warning of shallow water; it has been instrumental in discovering many unsuspected banks in imperfectly surveyed waters. By means of a single stout wire the sinker, an inverted kite, called the "sentry," can be towed steadily for any length of time, at any required

when a given length of wire is paid out is not changed by any variation of speed between five and 13 knots.

The kite in its position when being towed is indicated in fig. 1. The point of the catch C, passing through a thimble M in the short leg of the sling, is slipped into the hole at the top of trigger T, which is hinged at K and kept in its place by the spring S attached to the hook H. On the trigger striking the bottom the catch is released, the short leg of the sling slips off, and the sentry, which then rises to the surface, is left towing by the long leg. The winch is fitted with two handles for heaving in the wire; one gives great power and slow speed, and the other, acting on the drum spindle direct, winds in quickly. The wire supplied with the machine has a steady breaking strain of about 1,000 lb.

Echo Sounding .- This new method depends upon the principle that any sound originating at or near the surface travels through the water at a known speed, and after striking any large object or the bottom of the sea is reflected back to the surface, the time being a matter for accurate measurement.

The time necessary for obtaining a sounding is almost infinitesimal, the sounding in extreme depths taking little more time than one in the shallowest water. The speed of the vessel is maintained throughout the soundings, the soundings themselves may be accurately taken at extremely short intervals and bad weather does not affect the work. See also CHART and SOUND.

See Echo Sounding published by H.M Stationery Office. (J A. Ep.) SOUND MOTION PICTURES: see Motion Pictures: Sound Motion Picture Technology.

SOUP, a liquid food consisting usually of stock (water in which meat or vegetables have been boiled) with or without other ingredients. Soups are also made without stock. As clear soups are largely water, they have little food value in themselves, but they act as appetizers. Cream soups, vegetable purées and chow-ders are higher in food value and may be used as main dishes. (See also Cookery.)

SOUR-SOP, called also guanabana (botanical name Annona muricata; family Annonaceae), a small evergreen tree, about 20 ft. high, native to tropical America. It bears a large, dark-green, bluntly conical or heart-shaped fruit, 6 to 8 in. long and 1 to 5 lb, in weight, covered with short fleshy spines. The white, juicy, slightly acid, aromatic pulp has a flavour of mange and pine apple and makes excellent jelly and preserves. The sour-sop is cultivated in the West Indies, tropical South America, Mexico, India, Cochin China, parts of Polynesia and the west coast of Africa. With some frost protection, it can be grown along the Florida coast as far north as Palm Beach. It is propagated by growing seedlings and by shield-budding. (See Cherimova; Custard Apple; Sweet-sop.)

SOUSA, JOHN PHILIP (1854-1932), American composer and bandmaster, was born at Washington, D.C., on Nov. 6, 1854. His grandparents were Portuguese refugees. He was a pupil of John Esputa and G. F. Benkert for harmony and composition, beginning his musical education at six. At 19 he conducted for Milton Nobles; played in Offenbach's orchestra, Centennial exhibition, Philadelphia, in 1876, and conducted H.M.S. Pinafore before Gilbert and Sullivan went to America, in 1879, for the New York production. In 1880, he became bandmaster of the U.S. Marine Corps band, which acquired a high reputation under his control. The title of the "march king" was bestowed upon him by an English brass band journal for his many marches. In 1892 he organized Sousa's band, which won great renown. It visited Europe (1900, 1901 and 1903) and toured the world (1910-12). The golden jubilee of this veteran bandmaster and composer was celebrated in 1927. Belgian, English and French decorations were awarded him. His compositions include the comic operas, The Smugglers, Désirée, Queen of Hearts, El Capitán, The Bride Elect, The Charlatan, Chris and the Wonderful Lamp, The Free Lance, The Glass Blowers and The American Maid; many songs; 15 suites; more than 100 marches, of which the most popular were The Washington Post, High School Cavertical depth to 40 fathoms; should it strike the bottom, it will dets, Liberty Bell, Semper Fidelis and The Stars and Stripes free itself and rise to the surface, simultaneously sounding an Forever; The Chariot Race (Ben Hur), a symphonic poem. alarm gong. The vertical depth at which the sentry sets itself He wrote The Fifth String, Pipetown Sandy, Through the Year with Sousa and an autobiography He died March 6, 1932.

SOUSA, LUIZ DE [MANOEL DE SOUSA COUTINHO] (1555-1632), Portuguese historian, was born at Santarem, a member of the noble family of Sousa Coutinho. In 1576 he broke off his studies at Coimbra university to join the order of Malta and shortly afterward was captured at sea by Moorish pirates and taken prisoner to Argel, where he met Cervantes A year later Coutinho was ransomed and, landing on the coast of Aragon, passed through Valencia, where he made the acquaintance of the poet Jaime Falcão, who seems to have inspired him with a taste for study and a quiet life. National disasters and family troubles increased this desire, which was confirmed when he returned to Portugal after the battle of Alcacer and had the sorrow of witnessing the Spanish invasion and the loss of his country's independence Between 1584 and 1586 he married Settling at Almada, on the Tagus opposite Lisbon, he divided his time between domestic affairs, literary studies and his military duties as colonel of a regiment. His patriotic dislike of an alien rule grew stronger as he saw Portugal exploited by her powerful partner, and it was ultimately brought to a head in 1599. In that year, to escape the pestilence that devastated Lisbon, the governors of the kingdom for Philip II decided to move their quarters to Coutinho's residence Finding his protest against this arbitrary resolution unificeded, he set fire to his house, and to escape the consequences of his courageous act had to leave Portugal Going to Madrid, he not only avoided any penalty, owing no doubt to his position and influence at the Spanish court, but was able to pursue his literary studies in peace and to publish the works of his friend Falcão (Madrid, 1600). Nothing is known of how he passed the next 13 years, although there is a tradition that, at the instance of a brother, resident in Panamá, who held out the prospect of large commercial gains, he spent some time in America. It is said that fortune was unpropitious, and that this, together with the news of the death of his only child, caused his return home about 1604. In 1613 he and his wife agreed to a separation and he took the Dominican habit in the convent of Bemfica, while his wife entered the convent of Sacramento at Alcantara.

In 1616, on the death of Frei Luiz Cacegas, another notable Dominican who had collected materials for a history of the order and for a life of the famous archbishop of Braga, D. Frei Bartholomew of the Martyrs, the task of writing these books was confided to Frei Luiz. The Life of the Archbishop appears in 1619, and the first part of the Chronicle of St. Dominic in 1623, while the second and third parts appeared posthumously in 1662 and 1678; in addition he wrote, by order of the government, the Annals of D. John III, which were published by Herculano in 1846. After a life of about 19 years spent in religion, he died in 1632, leaving behind him a memory of strict observance and personal holiness.

The Chronicle of St. Dominic and the Life of the Archbishop have the defect of most monastic writings—they relate for the most part only the good, and exaggerate it without scruple, and they admit all sorts of prodigies, so long as these tend to increase devotion. Their order and arrangement, however, are admirable, and the lucid, polished style, purity of diction, and simple, vivid descriptions, entitle Frei Luiz de Sousa to rank as a great prose writer. His prose is characterized by elegance, sweetness and strength, and is remarkably free from the affectations and false rhetoric that characterized the age. In addition to his other gifts, Frei Luiz de Sousa was a good Latin poet.

There are many editions of the *Life of the Archbishop*, and it appeared in French (Paris, 1663, 1679 and 1825), in Italian (Rome, 1727-281), in Spanish (Madrid, 1645 and 1727) and in English (London, 1890). The *Historia de S. Domingos* may be read in a modern edition, 6 vol. (Lisbon, 1866).

Bibliography — Obras de D Francisco Alexandre Lobo, ii, 61-171; Innocencio da Silva, Diccionario bibliographico portuguez, v, 327, xvi, 72; Dr. Sousa Viterbo, Manoel de Sousa Coutinho (Lisbon, 1902).

SOUSLIK (Citellus: Sciuridae), the Russian name for a group of small squirrel-like animals, with cheek pouches and flattened tails, comprising some 80 species, found in unforested regions of the northern hemisphere. One species formerly inhabited Great Britain. In the United States some 20 species

occur. These are commonly called ground squirrels or gophers, of which one of the best known is the striped gopher (C. tridecemlineatus), found from Ohio to Montana and New Mexico.

SOUSSE, a city of Tunisia on the gulf of Hammamet, in 35° 49' N. and 10° 39' E, 36 mi by rail N E. of Kairouan, of which it is the port, and 93 mi. SE of Tunis Pop. (1946) 36,566 (of whom 5,937 were French), nearly three times that at the time of the French occupation in 1881. Sousse (formerly Susa) occupies part of the site of the ancient Hadrumetum, an important Phoenician city which served Hannibal as his base of operations at the end of the Second Punic War Trajan made it a colony. and about AD. 300 it became the capital of the new province of Byzacena. Later it received the name of Justinianopolis In the 9th century it was fortified by the Aghlabite rulers of Kairouan. It shared the general fortunes of Tunisia and became a noted haunt of pirates who raided the coast of Italy. In 1537, it was unsuccessfully besieged by the maiguis of Terra Nova, in the service of Charles V, but in 1539 was captured for the emperor by Andrea Doria. As soon as the imperial forces were withdrawn it became again the seat of Turkish piracy. The town was attacked by the French and the Knights of St. John in 1770 and by the Venetians in 1764. It remained, however, in the possession of the bey of Tunis In 1881 it was captured by the French, and in April 1943 by the British 8th army during the North African campaign in World War II, after advancing 80 mi, from Sfax in two days

The town is built on the side of a hill sloping seaward and is surrounded by a crenellated wall, strengthened by towers Recesses in the inner side of the wall are used as shops and warehouses. The kasbah, or citadel, built on the highest point within the town, was thoroughly restored by the French after their occupation of the country. Interesting buildings in the old town are the Kasr-er-Ribat, a square fortress with a high tower and seven bastions, built not later than the 9th century A.D., and the Kahwatel-Kubba (Café of the Dome), a curious house, square at the base, then cylindrical, and surmounted by a fluted dome. It was probably a church during the Byzantine period Southwest of the town are vast Christian catacombs, excavated by Abbé Leynaud in 1904 which contained some 10,000 burials. The ancient harbours are silted up, but vestiges of the Roman breakwaters may be seen. The modern port was completed in 1901. Exports are chiefly phosphates and other minerals, olive oil, esparto and cereals

SOUTH, ROBERT (1634-1716), English divine, was born at Hackney, Middlesex, in Sept. 1634. He was educated at Westminster school and at Christ Church, Oxford. Before taking orders in 1658 he was in the habit of preaching as the champion of Calvinism against Socinianism and Arminianism. He also at this time showed a leaning to Presbyterianism, but on the approach of the Restoration his views on church government underwent a change. On Aug. 10, 1660, he was chosen public orator of the university, and in 1661 domestic chaplain to Lord Clarendon. In March 1663 he was made prebendary of Westminster. In 1667 he became chaplain to the duke of York. He was a zealous advocate of the doctrine of passive obedience, and strongly opposed the Toleration act. In 1676 he was appointed chaplain to Lawrence Hyde (afterwards earl of Rochester), ambassadorextraordinary to the king of Poland. In 1678 he was presented to the rectory of Islip, Oxfordshire. In 1693 South published with transparent anonymity Animadversions on Dr. Sherlock's Book, entitled a Vindication of the Holy and Ever Blessed Trinity, in which the views of William Sherlock were attacked with much sarcastic bitterness.

Sherlock, in answer, published A Defence in 1694, to which South replied in Tritheism Charged upon Dr. Sherlock's New Notion of the Trinity, and the Charge Made Good. The controversy was finally stopped by the king. In 1710 he ranked himself among the partisans of Henry Sacheverell. He declined the see of Rochester and the deanery of Westminster in 1713. He died on July 8, 1716, and was buried in Westminster abbey.

His Sermons (6 vol., 1692) were reprinted many times; there is a modern edition in Bohn's classics (2 vol., 1845), and a complete edition

of his Works (5 vol , 1842). See also W. C. Lake, Classic Preachers of the English Church (1st series, 1877)

SOUTH, THE, a large area of the United States with certain distinctive characteristics The nation's southeastern quarter includes six of the original 13 states-Delaware, Maryland and the District of Columbia, Virginia, North Carolina, South Carolina and Georgia; and 11 states added after formation of the union-Kentucky (1792), Tennessee (1796), Louisiana (1812), Mississippi (1817), Alabama (1819), Missouri (1821), Arkansas (1836), Florida (1845), Texas (1845), West Virginia (1863) and Oklahoma (1907) Delaware, Maryland, West Virginia, Kentucky and Missouri often are referred to as border states because of their locations between the south and north and consequent mingling of northern and southern characteristics During the American Civil War the border states, although slave-holding, did not second from the union Today only southeast Missouri exhibits southern characteristies, the rest of the state is midwestern. Delaware and much of eastern Maryland consider themselves northern areas. while industrialized northern West Virginia closely resembles Pennsylvania Peninsular Florida is not "southern." since its environments, settlements and economic development differ from the rest of the south Western Texas and Oklahoma exhibit primarily western characteristics although settled primarily by southerners

Regional Features.-The distinctive features of the south are the following: a uniformly mild, humid climate with a long growing season; soils of moderate to low fertility, called red-yellow earths, which generally are productive under proper management but are easily eroded, gently rolling to dissected plainsland terrain, interspersed with alluvial valleys and extensive areas of hill-lands and low mountains; a biracial population consisting of a white majority of Scotch-Irish oiigin, and a Negro minority descended from the ante-bellum slave population; the plantation heritage, which disseminated the Negro and large landholdings throughout the southern plainslands; share-cropism and rural tenancy, which appeared as the large landholdings were fragmented during reconstruction; incipient farm mechanization; the yeoman farmer tradition and small farms, found in the nonslaveholding Appalachian hill-land areas; the one-party political system; and the rural agrarian tradition.

Only one of these features applies to all segments of the area called the south: the uniformly mild climate. While definitely a southern feature and an asset, and while it has been conducive to much that has happened in southern history—such as cotton, rice and tobacco culture and the associated plantation and slavery institutions—it is not climate that provides distinctiveness to the area. Instead, it is a complex of cultural and economic aspects which distinguish the region.

These unique cultural and economic facets stem primarily from the reconstruction period following the Civil War. Biracism became more than a population statistic during that time. Whereas formerly the dominance of the white was unquestioned, with abolition of slavery the landowner found it necessary to combat what were considered "carpetbag" and "scalawag" impositions in favour of the Negro. The share-crop system was devised. Reconstruction created conditions unattractive to outside capital and to European immigrants, and fixed a rural-agrarian pattern which only now is being torn apart. It was during reconstruction that the one-party Democratic tradition was developed. Finally, low per capita incomes, rural poverty, and inadequate public services (especially schools) which plagued the south were in large part consequences of capital losses during reconstruction.

The core of the south consists of those areas which experienced federally-supervised reconstruction and occupation by federal troops. These are the states comprising the Gulf and South Atlantic coastal plains. The border states and Appalachian hill-lands, since they escaped reconstruction, exhibit progressively fewer and fewer southern characteristics and now are "southern" primarily by geographical position and only secondarily by characteristics of landscape, culture and economy.

Climate.—A long growing season (generally 200 to 290 days frost-free) during which temperatures are warm to hot, together

with abundant rainfall during all seasons is experienced throughout the south. Winters are mild, the areal majority of the south averages 40° F, or higher during January, and extended snowcover is rare except in the Appalachian hill-lands Annual rainfall averages 45 to 50 in for most of the region, with greatest precipitation occurring during late winter and early spring. Late summer and autumn are drier and sunnier than other seasons-which facilitates crop harvesting. Summer rainfall is characterized by numerous thunderstorms and torrential downpours. Each autumn some parts of the Florida, Gulf and South Atlantic coasts experience heavy rains from hurricanes which move inland from adjacent seas; two or three of these storms each year contain winds of destructive force. The south experiences more tornadoes than other U.S. areas; they occur most frequently during spring and are most common in the Mississippi valley and adjacent states. The long growing season and abundant moisture permit production of a large number of agricultural and horticultural specialties, because of mild winter temperatures many field and truck crops can be produced on a year-round basis.

Landforms.—Two great landform categories predominate. hilllands which are deeply dissected (including some low mountains), and broad, gently rolling to moderately dissected plains.

The Appalachian hill-lands, consisting of the Blue Ridge, Appalachian ridge and valley, and Cumberland plateau, is the largest hill region in the south

The Blue Ridge, an area of intensely metamorphosed and crystalline rocks, begins in northern Georgia, widens to include extensive areas in eastern Tennessee and western North Carolina (where it reaches elevations exceeding 6,000 ft, and relief in excess, locally, of 2,000 ft. and is known as the Great Smoky mountains), narrows again and extends as a thin ridge throughout western Virginia and Maryland into Pennsylvania. The Appalachian ridge and valley, consisting of deeply folded sedimentary Palaeozoic rocks, is situated immediately northwest of the Blue Ridge. Broad, open, limestone-floored valleys which trend northeast-southwestward. approximately parallel to one another, are separated from one another by steep-sided, level-crested linear hills of sandstones and The valleys are drained by such famous streams as the Shenandoah, the upper James, the Holston and the Clinch. Historically, the limestone valleys have served as passageways for traffic moving southwestward and have acted as funnels between the Blue Ridge and the steep east-facing escarpment (Allegheny Front) of the Cumberland plateau. The limestone valleys are fertile, densely settled, and sites of the larger cities in the Appalachian hill-lands. The Appalachian ridge and valley extends from Birmingham, Ala., through eastern Tennessee (Chattanooga, Knoxville, Morristown, Elizabethton) and western Virginia (Bristol, Salem, Staunton, Lexington, Winchester) into central Maryland and Pennsylvania. The Cumberland plateau, consisting of nearly-horizontal layers of sedimentary rocks, forms the northwestern boundary of the Appalachian ridge and valley. The plateau consists of sandstones which slope gently westward. Its undissected surface rolls gently and in northern Alabama and eastern Tennessee is occupied by many small farms. Westwardflowing streams have cut into the plateau vigorously and deep, steep-sided valleys have resulted. Dissection by streams is intense on its westernmost third. Valleys support most of the set-tlements and cultivated land. Throughout the Appalachian hilllands slopes and uplands generally are heavily wooded.

The Ozark-Ouachita hill-lands of southern Missouri, western Arkansas and eastern Oklahoma are similar to the Appalachians although local relief is not as great and the areas involved are smaller.

Southern hill-lands differ from the plainslands in certain cultural and economic characteristics. In the hill-lands, the percentage of rural population is greater, but settlements are concentrated in favourable locales—valleys, mountain "coves" and lower valley slopes. Extensive sparsely populated areas occur in the hill-lands. The Appalachian hill-lands were originally settled by Scotch-Irish frontiersmen who moved from Virginia and central Pennsylvania down the open valleys; these settlers did not espouse the plantation system. Consequently small landholdings pre-

dominate in the hill-lands, and the percentage of population which is Negro is small. Virtual absence of the Negro explains the Union sympathy expressed throughout the Civil War and the widespiead loyalty to the Republican party throughout these areas in later years. Landholdings, soils and cultivation practices have not been suited to the great staple crops of the lower south—cotton, cane sugar and rice. Diversified livestock and subsistence farming have prevailed historically. Except for petroleum, the Cumberland plateau and the Appalachian ridge and valley areas have been and are the south's leading mining areas, notably in iron ore (Binningham and Gadsden, Ala.) and bituminous coal output (northern Alabama, eastern Tennessee, Kentucky and West Virginia).

The South Atlantic and Gulf coastal plains, coupled with the southern Piedmont and limestone-basin plains of central Kentucky and Tennessee are the southern cultural coreland These plains extend from the Atlantic coast to the Blue Ridge, and from the Potomac southwestward across the lower Mississippi valley to the Rio Grande river. Southern plainslands are of four types: (1) alluvial river valleys such as those of the lower Mississippi, the lower Rio Grande, Colorado, Brazos, Red, Arkansas, Alabama, Chattahoochee, Altamaha, Santee and Roanoke rivers; (2) fertile plains underlain by limestones which have decomposed into dark chestnut-brown or brownish-black soils such as the Louisville-Lexington bluegrass basin of central Kentucky, the Nashville basin of central Tennessee, the black belt extending from Columbus, Ga., westward through Montgomery and Selma, Ala.; Columbus, Miss.; ending north of Tupelo, Miss.; and the black wax prairies of central Texas, which extend from the Red river near Sherman and Denison, south-southwestward including Dallas, Fort Worth, Waco, Austin and San Antonio, Tex; (3) the southern Piedmont, whose inner margin is the Blue Ridge and whose seaward boundary is referred to as the fall line, a region of crystalline, commonly highly metamorphosed, rock whose rolling surface has been strongly dissected by numerous streams; (4) the coastal plains, extending from the Mexican border to Maryland, consisting of loosely consolidated, or unconsolidated sedimentary materials which generally range from coarse to sandy and whose moderate stream dissection has created undulating to moderately rolling plains. Seaward margins of the coastal plains are flat, poorly drained, and indented by many tidal marshes. Along the fall line changes in stream gradients flowing from the Piedmont onto the coastal plains cause rapids (whence the name fall line) which constituted heads of navigation for small vessels during colonial times.

Stream valleys are flat, poorly drained to marshy, heavily wooded and relatively difficult to cross throughout the coastal plains. On the lower Piedmont stream flow is more rapid, valleys are narrower, better drained, and more easily traversed. Interfluves are broad and well-drained. The Scotch-Irish of Virginia and Pennsylvania, the south's frontiersmen, preferred travel on the lower Piedmont to migration across the inner coastal plains for obvious topographic reasons. When the frontiersmen swung out of the ridge and valley of western Virginia on to the Piedmont through the Roanoke gap, they pushed the frontier along the lower Piedmont toward the Alabama black belt, creating a tonguelike settled area from which settlements subsequently rippled out toward both the Blue Ridge and the coastal plains to the south. Subsequent migrations of planters, from tidewater Virginia, North and South Carolina, followed the same route when the cotton plantations of the lower south were established during the early 1800s. Other Scotch-Irish frontiersmen moved southward through the Appalachian ridge and valley to gaps (such as the Cumberland gap in southwestern Virginia) through the east face of the Cumber-land plateau, thence followed valleys into central Kentucky and Tennessee. Some tobacco planters followed this frontier wedge into the limestone basins. Plantation migration via the gaps, howc.er. was numerically much smaller than via the lower Piedmont. Since settlement the southern Blue Ridge has been a serious barrier to migration and transportation and has diverted the main streams i raffic around the southern margins of the hill-lands.

As tidewater planters moved into the interior they searched for and sufficiently level to permit large fields for efficient employment of large gangs of slaves. The lower Piedmont and coastal plains provided such land; the hill-lands did not. Consequently, except for isolated instances, the plantations were located outside the hill-lands and, since migration of the planters spread the Negro slaves throughout the plantalands, it is in these areas that large farms—descendents of the plantations—and the southern Negro population are found today.

Soils.—Predominantly lateritic soils of reddish-yellow colour and coarse texture are characteristic of most of the south. In the Appalachian hill-lands and upper (northern) south generally, podsolizing processes have created grayish-brown surface colours and coarse substrata. As a whole, southern soils are mediocre in fertility; commonly they are deficient in calcium, nitrogen, phosphorous and potassium compounds. These soluble alkalines never were present in large amounts because southern soils formed under heavy rainfall, which caused alkalines to go into solution and disappear readily. Most southern soils were exhausted quickly after cultivation began; characteristically the south has consumed slightly more than half the nation's commercial fertilizer output. The average soils are moderately to strongly acid, are easily cultivated and, when lime and appropriate fertilizer are added, respond readily.

Certain southern regions are notable for inherently high soil fertility; they are an areal minority, however. The limestone plains of central Kentucky, central Tennessee, the black belt, and the black wax prairies are outstanding, as are also the limestone-based soils of the Appalachan ridge and valley. Soils developed upon alluvium in river-valley plains, as in the Mississippi valley. characteristically are well above the regional norms in fertility and productivity as are also the brown silt loams immediately east of the Mississippi river flood-plain and parallel to it from southern Illinois to Louisiana.

Soil depletion and erosion have been major problems in the south since before the Civil War. Soil depletion was accelerated during plantation decades by emphasis upon cash crops, and following the Civil War the necessity for cash staples such as cotton and subsistence grains caused further depletion. Constant summer row-cropping, associated with haphazard or no crop rotation was the custom as late as 1920. These practices in a region with a humid climate characterized by frequent torrential rains and virtually no extended soil freezing during winter led to widespread soil erosion. By 1930 major erosion damage characterized most of the south. Topsoil had virtually disappeared in large areas, notably in the Piedmont. The soil conservation service and associated agencies of the U.S. department of agriculture after 1033 promoted adoption of conservation practices to counteract depletion and retard erosion by incentive payments to farmers who employ approved land management practices. By 1950, erosion ravages had been checked in most southern areas, although erosion itself was by no means eliminated.

Biracial Population.-The biracial character of the south is distinctive. The original Atlantic coast settlements on the James river, Virginia, at Charleston, S.C., Brunswick, N.C., and Savannah, Ga., were established by English settlers, and migrants did not move inland from these centres until Scotch-Irish frontiersmen had migrated southwestward along the lower Piedmont behind the coastal nucleii. As settlers migrated inland from the coastal centres, they joined with the Scotch-Irish to populate virtually all of the south except the French settlements of lower Louisiana. The south was not attractive to the great majority of European immigrants who entered the United States between 1870 and 1920 because the region contained no free land which could be homesteaded and few industries which could offer ready employment, and because wages for agricultural labour competitive with former Negro slave labour were unattractive. Since the south did not share in European migration into the nation, it remained distinctively uniform in the composition of its white population-most of whom are descended from early immigrants from the British Isles.

Negro slaves were imported into the coastal tobacco areas of Virginia as early as 1619 in small numbers, but their use as the labour force for plantations originated elsewhere. Slave importation in numbers began in approximately 1695 near Charleston,

S.C., under the aegis of former Barbadians who had discovered opportunities for rice production. These settlers transplanted the plantation system of large-scale sugar production, with associated Negro slave labour, into the new rice area. After 1742 indigo developed as a plantation crop in South Carolina and Negro slaves also became the labour force in its production. Use of Negro slaves as a plantation labour force spread into tidewater Maryland-Virginia settlements, and into Georgia after 1752. Prior to the Revolutionary War the West Indian Islands were principal sources of imported slaves. Importation ended in 1808; approximately 450,000 had been imported and the national population of Negroes -slaves and free-was approximately 1,378,000 in 1810. 1950 American Negro population of 15,073,776, of which about two-thirds resided in the south, had descended almost entirely from imported slaves.

Invention of the cotton gin in 1793 reduced the cost and the time spent in separating cotton fibres from the seed, and generated tremendous increases in cotton production. Accelerated demand for cotton in Europe, as a consequence of the industrial revolution, stimulated seaboard landowners to migrate to the interior and commence cotton cultivation. Cotton production rose to 178,000 bales annually by 1810, and to 4,508,000 bales in 1850.

Negro slavery and the plantation system were readily adaptable to cotton culture. As settlements rapidly spread westward after 1810, the slavery and plantation institutions were dispersed throughout the southern plainslands and predominated in areas most favoured by natural conditions for cotton production. Such areas as the lower Georgia-Carolina Piedmont and inner coastal plains, southwest Georgia and southeast Alabama, the Alabama black belt, the lower Mississippi valley and the black wax prairies became noted for plantations. Their former status was reflected in modern times by the large percentage of Negroes in their population and large individual landholdings. Following 1810, the tidewater plantation tobacco industry found new lands in Kentucky and Tennessee, and sugar plantations developed rapidly in southern Louisiana; in both instances slavery was intrinsic to production of the staple crop. The modern concentration of the Negro on the plainslands resulted from the association of slavery with plantation land occupance. Had it not been for widespread dispersal of the plantations the south would not be biracial.

Plantations and Tenancy.—The plantation was an essential aspect of the ante-bellum south. Former plantations are still recognizable in altered form in many southern areas. In 1790 the populations of north and south were practically equal (1,967,197 and 1.062.428 respectively), and their influences within the federal government were about equal also. In succeeding decades up to 1860 the northern population grew at a greater rate than did that of the south. The consequent proportional loss (1860: 20,-309.960 northern; 11,133,361 southern) forced the south to wage a desperate struggle to retain its influence in the federal government to protect its particular interests, chief of which were slavery and the plantation system. As long as the number of free and slave states remained about equal, the south retained its influence in the U.S. senate. However, admission of California as a free state in 1850 foretold the decreasing power of the south in the senate, and led the south to espouse the doctrine of state sovereignty to protect its interests. In defense of slavery, primarily, the southern states followed the doctrine of state sovereignty to its ultimate conclusion and seceded from the union, forming the Confederate States of America. After four years of civil war the south was left beaten, exhausted and economically destitute. Freedom for the Negroes destroyed the slavery institution and the economic and social aspects of the plantation system as well, but did not remove the geographic basis of the plantations. The large landholdings intrinsic to the plantations became the areal bases upon which southern rural tenancy and share-crop agriculture developed during the reconstruction era.

At the close of the Civil War plantation owners were without operating capital or labour supply. Former slaves were without personal resources and had neither land, tools nor work stock with which to farm. Gradually the two groups evolved a system of land use, reasonably satisfactory to each, known as the sharecrop system. The former slaves no longer worked in gangs, directed successively by a central management to one large plantation field after another. They no longer were closely supervised in the routine tasks of farming, nor did they reside in a centrally located plantation slave row. Each Negro became a semiindependent operator farming a small subunit of 20 to 70 ac. Each subunit contained two or three small fields, and the former slave usually resided in a cabin at the edge of one of these Customarily his landlord provided him with tools, work stock, seed, and sufficient credit (called furnish) to purchase foodstuffs and a minimum of other goods until cash was on hand at harvest time.

When the staple crop was harvested, landlord and sharecropper split the crop proceeds half-and-half (hence the term "sharecropper"). The landlord received half the crop as rent for his land, buildings, animals and tools, and payment for his share of seed and fertilizer; the cropper received his half for his labour. Payment of the landlord's furnish came at harvest time from the cropper's share and took precedence over any other encumbrance

on the cropper.

The legislatures of southern states enacted crop-lien laws during reconstruction. These laws insured payment of the landlord's furnish ahead of other obligations and legalized the cropperlandlord relationship. Most landlords possessed insufficient capital to furnish croppers during the postwar period. They borrowed funds not only for their own support but also to reloan to their croppers. Crop-lien laws covered this relationship also. These laws still are operative; in no other section of the nation did it become customary to mortgage a crop or commodity that does not exist to relend to individuals who possess insufficient capital goods to secure the loan. Obviously these laws are outgrowths of reconstruction exigencies.

As the plantation workers changed from slave gangs to sharecroppers, settlement patterns shifted from centralized housesites to widely dispersed ones, from large fields to many small ones, from large compact woodlots to numerous small, irregularly shaped ones. Thus the plantations were fragmented. (The U.S. bureau of the census first recognized each share-crop unit as a separate farm in 1870). Only the land itself remained under central ownership, with fragmentation central management disappeared.

Another phase of plantation fragmentation created the tenancy system. The tenants represented a more advanced economic group in that they owned their work animals and tools. Since the landlord furnished the tenant only with land and buildings, his rent customarily amounted to one-third of the crop while the tenant retained two-thirds. Otherwise tenant relationships paralleled cropper relationships and were legalized under crop-lien laws. Tenancy arose largely during the period 1880-1900 in response to the modest financial independence of many croppers. Cropper and tenant systems still predominated in the former plantation areas in the 1950s though not to the extent that they did until 1930.

The Neoplantations.-During the decade 1940-1950 machines appeared on southern farms in large numbers for the first time. Many former plantation owners found it necessary to abandon cropper or tenant systems of land management when machines were purchased because most machines do not operate efficiently upon small land units. When cropper or tenant subunits of the fragmented plantations were coalesced into large fields, centralized management reappeared. Former cropper houses were abandoned, and housesites in use were clustered around the operator's home. Fields were fenced. A smaller labour force was applied as a unit to the entire plantation area to produce one or two commodities in which the plantation specialized and which also were capable of production with machines. These "neoplantations" were observable by 1950 in every former plantation area of the south and, while not as numerous as fragmented plantations, were increasing in importance. Labourers employed on neoplantations customarily received their houses and gardens free, and were paid a cash wage plus annual bonus. The labour force on a neoplantation was one-fourth to one-third that on a fragmented plantation with the same cropland acreage.

The Small Farm Tradition .- The southern landscape is distinctive since it shows the effect of two great processes in national settlement: migration of the frontier and of the plantations "Poor whites" who possessed only a few simple implements fanned out to either side of the lower Piedmont channel of migration and settled the upper Piedmont in North and South Carolina and Georgia, northern Alabama, the Blue Ridge, the lower coastal plains in southeastern Georgia, southwestern Alabama, southern Arkansas and eastern Texas. The Ozark-Ouachita hill-lands, also unattractive to planters, were settled in small farms by independent landholders. The term "yeomen farmers" has been applied to the smallholding group by historians.

During the decades 1930–1950 numerous small farms appeared around the south's growing urban centures. They represented one phase of national "rurban-suburban" growth Many are operated by "sun-up farmers"; i.e., operators whose primary income is from urban employment but who live outside the city on small units which they farm before working hours and on weekends. Many small landholdings are sandwiched among large units in every former plantation area. Except in the Mississippi valley, small landholdings, each containing less than 100 ac of cropland, are more numerous than plantation landholdings; however, the largeholdings usually occupy greater total area.

Following settlement, smallholdings were primarily subsistence farms with a single cash-crop specialty such as cotton, tobacco or corn grown on a minority of the acreage. After 1930 many of these farms shifted toward specialized commercial operations such as broiler chicken production (northern Georgia), burley tobacco (eastern Tennessee and western North Carolina), fruits and truck crops (northwestern Arkansas), and dairying (northeastern Alabama and southeastern Tennessee). Many of these farms were too small for effective support of farm families. They became an important source of labour to supply the south's expanding textile mills, wood-processing plants and chemical industries. Outside of "rurbar-suburban" locales, the number of smallholdings declined between 1940 and 1950, and their average size increased.

Democratic Vote in the South.—Another distinctly southern characteristic is the one-party political system. The "solid south" is a political fact. Loyalty to the Democratic party began during the reconstruction period. Approximately \$1,000,000,000 of southern capital vanished in freeing the slaves. Cotton produced during the war, which had been stored in public warehouses because of the Federal blockade, was confiscated by the Federal government without indemnity. Most southerners had only land left. Work animals and implements necessary for cultivation had been subjected to pilferage by freedmen, marauding bands from both armies, and occasional systematic confiscation.

Swarms of opportunists called carpetbaggers poured into the south determined to make fortunes quickly by capitalizing upon the prostrate land. They were joined by local opportunists known as scalawags. These groups co-operated openly with Federal military governments established in 1867, and exploited the freed Negroes, many of whom sat in state legislatures. The extravagances of legislatures consisting of these three groups created such heavy bonded indebtedness that all southern states later were compelled to repudiate their debts, an action which destroyed public credit for many years. It was a Republican administration which defeated the Confederacy; other Republican administration sadministered reconstruction. Carpetbaggers, scalawags and Negroes had ruled, under the protection of federal occupation, as Republicans. The freed Negroes espoused the Republican party.

The white population of the plainslands associated the Republican party with the bitterest experiences in the life of the south; thus the Democratic party became both a refuge and a tool for overthrow of the carpetbag governments in the minds of the great majority.

The solidly Democratic preference continued from the close of reconstruction with three exceptions. In the 1928 presidential campaign, numbers of southern Democrats bolted in favour of Herbert Hoover over Alfred E. Smith. In 1948 a minority of southern states bolted the Democratic party to form a short-lived "splinter"-party known as States' Rights Democrats. This group contained conservative Democratic southerners who were opposed to the Fair Deal policies of Democratic candidate Harry S. Tru-

man, but who could not accept the Republican party and its nominee. Thomas E Dewey The States' Rights group consisted of a dwindling but powerful minority who were political inheritors of the state sovereignty concept of ante-bellum times, albeit "sovereignty" had been altered to "rights" in the process of inheritance. Again in 1952 parts of the solid south slipped into the Republican column in support of Dwight D. Eisenhower.

Notable exceptions to dominance of the Democratic party are found in the Appalachian hill-lands. Eastern Tennessee and Kentucky, western North Carolina, and segments of southern West Virginia, southwestern Virginia and northern Georgia have been predominantly Republican since the Civil War When the Confederacy was founded these small-farm areas, with virtually no Negro population, opposed secession and were sympathetic to the Union cause. These hill-lands provided the Republican leadership during reconstruction and received the bulk of state patronage As a result these areas became the Republican strongheld in the south But the hill-lands did not occupy sufficient area in any one state at mid-20th century to influence materially its political life except in western North Carolina where a large Republican area could exercise balance of power in the event of a factional split among the Democrats.

The Democratic controlled state legislature gerrymandered county boundaries to create long east-west oriented counties, the eastern segments of which included sectors of the densely populated, strongly Democratic Piedmont The preponderant Democrats in each county thus could hold the divided Republicans of the Appalachians in check

Throughout the south it is taken for granted that the Democratic slate will win in a general election. Major political campaigns are fought to win nomination in the Democratic party primary. As a consequence, there are several factions within the Democratic party in each state. Most factions represent certain economic groups, areas or classes, such as the small landholders Factions in several states have won elections upon the issue of white supremacy, and still do. Normally the successful faction espouses two or three "causes" or special groups within its state.

The Rural-Agrarian Background.—The south has been historically a region of rural settlements devoted to agrarian pursuits. As late as 1940, 65,5% of the population was rural (1940 total: 38.915.061, excluding Delaware. Maryland and Missouri), and of the rural residents almost two-thirds resided on farms. Antebellum preoccupation with staple crops continued into the 1930s. Thereafter agricultural diversification proceeded at tremendous rates, but the agrarian economic basis persisted. By the 1950s the southern states had become the nation's largest producers of tobacco, peanuts, cane sugar, rice, peaches, pecans, watermelons, broilers and frying chickens, and of course cotton. The region also had become noted for its large corn, soybean, winter wheat, oats and legume seed production, and its expanding livestock industries, though it had not assumed leadership in any of these.

Despite rapid growth of urban centres and industrial pursuits, the rural-agrarian background continued to persist in the south. The fact that the population was overwhelmingly of rural origin conditioned economic and social viewpoints in the region to an extent not duplicated elsewhere in the nation.

Population Changes.—In 1940 the south's population of 38, 915,061 (exclusive of Maryland, Delaware and Missouri) constituted 29,55% of the national total; by 1950, 44,536,002 southerners accounted for 29.02% of national population. The south's population increase amounted to 12.39% and the nation's to 14.45% during the 1940–50 period.

Southern birth and net survival rates were higher than for the rest of the nation; had it not been for substantial emigration of both Negroes and whites, southern population would have increased more than it did.

The south's population changed most in place of residence and employment from 1940 to 1950. In 1940 urban population consisted of 13,407,609 (34.45% of the south's total) but by 1950 had increased to 20,338,560 (46.5% of the total). The number of rural residents declined from 25,507,452 (1940) to 23,395,264 (1950), or from 65,54% of the 1940 to 53,49% of the 1950 total.

The increment in percentage of urban residents represented an increase of approximately 51%, the largest of any American region Rural-farm population decreased from 16.055,181, or 62 0% of the regional total (1940), to 11,678,440, or 26.7% (1950), a decline of 4,376,721. This number does not balance the actual increase in urban population (6,930,851). Rural nonfarm population. which includes numerous small landowners in the suburban fringes. rose from 9,452,271 (1940) to 11,716,824 (1950). Whereas rural nonfarm residents accounted for slightly more than one-third of the rural population in 1940, they comprised slightly more than one-half of it in 1950 Thus primary population shifts during 1940-50 consisted of a major increase in urban numbers, an important increase in rural nontarm residents, and a major decline in farm population. Roughly half of the south's counties (almost all of which were rural ones) suffered decreases in population. The south was the only major region in the nation to experience an absolute as well as a relative decline in rural farm residents.

Southern Negro population urbanized and migrated from farms at approximately the same rates as did the total population during the 1940-50 period. In one important respect Negro population trends differed, the Negro migrated from the south faster than the white The proportion of Negroes in the south's population had decreased by 1950 to the lowest point in 100 years. Of 12,865,-518 Negroes in the nation in 1940, 9,379,546, or 72.9%, resided in the south, constituting 24.1% of the southern population. By 1050, national Negro numbers had increased to 15,073,776, virtually 10% of the total population. Negroes in the south totalled 8,911,933, or approximately 20 4% of all population, a decrease of 467,613 since 1940. Thus in 1950 the Negro was about twice as numerous in the south as in the nation. In 1860, when 38% of the south's population was Negro, the Negro was more than five times more numerous in the south than in the rest of the nation. During the 1949-50 decade. Negro population changes shifted the south's population composition much closer to the national average than it was prior to 1940.

Changes in Income and Income Sources .- Between 1930 and 1950 southern average per capita incomes increased approximately 300%, two-thirds of which occurred after 1940. Per capita incomes in the south in 1950 averaged approximately 62.5% of the national average of \$1,600. Part of the 1940-50 per capita income increase was attributable to a 34% decline in percentage of labour force employed in agriculture (32% in 1940, 21% in 1950). The proportion of employment provided by manufacturing, service and secondary industries rose greatly. In 1950 manufacturing alone accounted for 18% of the region's workers, an increase of about 7% over 1940. Manufacturing had become a larger source of income than agriculture by 1950 (agriculture \$3,100,000,000, manufacturing \$3,900,000,000, using a 1939 index dollar). This reversal of traditional income relationships was not a consequence of reduced agricultural income; income from agricultural sources rose from a pre-World War II average of approximately \$2,000,-000,000 (1939 index) to the figure noted above. Approximately 36% of the industrial structures contracted for in the nation between 1946 and 1949 were built in the south.

In 1950 trades and services accounted for approximately \$11,000,000,000 (1939 index), or about 26% of all southern income. The proportion of total income provided by this group had increased only about 2% since pre-World War II days. Income payments from federal and state government sources increased from approximately \$1,250,000,000 (1939 index) to about \$5,000,000,000 in 1950. This income source grew in proportionate significance from approximately 9% (1940) of all income to about 20% (1950).

# RURAL LAND USE

Changes in Farm Numbers and Acreage.—The number of farms in the south declined from 3,007,170 in 1940 to 2,650,803 in 1950. About 439,000 farms of less than 220 ac. in size vanished; 37,627 new farms of more than 220 ac. appeared. An estimated 100,000 tenant and share-crop farm units were absorbed into the large landholdings of which they were parts. Total land in farms increased from 370,168,461 ac. (1940) to 394,237,903 ac. (1950),

and average farm size rose from 123 to 149 ac. Greatest farm size increases occurred among farms larger than 220 ac.; however some increases were registered for smaller farms except those ranging from 3 to 30 ac. in size Cropland harvested per farm rose only from 34.3 to 36 ac during the 1940–50 decade; land pastured increased considerably, however. Average southern farm value increased 163%, from \$3,231 in 1940 to \$8.495 in 1950, and value per acre slightly more than doubled, nsing from \$26.75 to \$58.30 The greatest value per-acre increments occurred on farms of less than 30 ac.; these farms underwent about a threefold value increment—largely as a consequence of rising real estate values in the "rurban-suburban" locales in which many of them were situated. Value increases during the decade were significant nationally, since in 1950 about 49% of the nation's farms were in the south.

Forests and Forest Industries.—The south is more nearly a forest belt—not a cotton belt—than anything else. Excluding western Oklahoma and Texas, more than 55% of the regional area in 1950 was in forests, which together accounted for slightly more than 30% of the national forest acreage. About 40% of the nation's commercial forests are in the south. Public ownership of forest land is much less significant than elsewhere: roughly 86% of the forested acreage in 1947 was privately owned and about 40% of it on farms

Southern forests are of three major types. Largest in area and commercially most important is the southern coniferous forest of the coastal plains, which extends from Chesapeake bay to eastern Texas. Much of the forest land of the Piedmont, northern Alabama and Mississippi also is devoted to the southern pines although these areas originally were vegetated by hardwoods. Pines were introduced into these areas as second-growth because they were more valuable and reached merchantable size more rapidly than the hardwoods. Four varieties, loblolly, longleaf, shortleaf and slash pine predominate; the latter two are most important ereally. The pines are most valuable because they supply excellent structural lumber, are the best southern pulpwood source, and also may be used to produce naval stores. Mixed deciduous hardwoods predominate throughout the Appalachian and Ozark-Ouachita hilllands, and also throughout the plainslands of Kentucky, Tennessee, northern Mississippi and Arkansas. Predominant hardwood varieties are red and white oaks, hickories, maples, poplar and chestnut (virtually gone as consequence of the chestnut blight). The third type consists of alluvial-riverbottom hardwoods, including cypress, tupelo, red and sweet gum, and some white oak and lowland hickory varieties. Bottomland hardwood forest stands are most numerous in the Mississippi valley and valleys of its tributaries; Memphis, Tenn., is the nation's leading hardwood market largely because of its nearness to these forests.

Pulp, paper and timber companies own huge tracts, especially on the coastal plains east of the Mississippi river. By the 1950s the south was supplying half of the nation's annual timber growth. and about 55% of the annual saw-timber growth on only 21% of the national forest acreage devoted to trees of saw-timber size. There were about 1,650,000 small southern landholdings which included an average of 75 forested acres each. Southern forests were producing (1952) approximately 45% of the nation's lumber and timber, 50% of its fuel wood, and 58% of its pulpwood output. Southern forests produced the entire national supply of naval stores-turpentine and rosin. About 65% of all turpentine was produced from pine wood as a by-product of pulp-paper manufacture-a remarkable change since 1930, when less than one-seventh of the national output was so recovered. In 1951 the south produced approximately 708,000 bbl. of turpentine and 2,137,000 drums of rosin.

Restocking and replanting of southern forests proceeded rapidly, and inadequate forest stands were upgraded. In 1949 production goals for state-owned tree nurseries were set at 98,500,000 seedilings (almost entirely pine), and the U.S. forest services indicated that this output—about double that of the preceding year—would not remotely satisfy demand.

By 1952 there were about 670 paper, pulp and paperboard plants in the region, many of them of small size; 43 plants, each with a daily capacity exceeding 250 tons of processed products, ac-

counted for the vast majority of regional production. Five new plants were under construction, including a mammoth newsprint plant near Cleveland, Tenn., utilizing both pine and hardwoods for pulp. The gross value of products from these plants in 1951 exceeded \$2,300,000,000. Georgia (2,500,000 cords), Mississippi (1,865,000 cords), Alabama (1,609,000 cords) and Florida (1,583,-

000 cords) were the leading pulpwood producers.

The percentage of area in forest is so great in certain parts of the south that these locales must be considered forest regions. These regions are (1) the Appalachian hill-lands from northern Georgia through the western Carolinas, eastern Tennessee and western Virginia; (2) the lower coastal plain in northern Florida, southeastern Georgia and southers Mississippi; (4) southern Arkansas; (5) west-central Louisiana and southeastern Texas; (6) northern Arkansas; and (7) the Cumberland plateau forest in eastern Tennessee, Kentucky and northern Alabama. The southeastern Georgia-northern Florida region contains county after county with more than 90% of the area in forest. Throughout all of the foregoing regions approximately 80% or more of the total area is forested.

Cotton Production Changes.—The most fundamental change in southern land use was the decline in acreage planted to cotton. Acreage in cotton between 1944 and 1950 was between 20,000,000 and 24,000,000 ac., about 44% less than in 1924–25. If production had declined as much as did acreage, the consequences could have been disastrous, but such was not the case. In the 1925–50 period eastern Texas-Oklahoma yields per acre increased about 25%, and regions east of the Mississippi averaged more than 50% increases. Raw cotton prices rose steadily from 1930 onward because of the AA:A. (Agricultural Adjustment Administration) price-parity formula for cotton and the demand created by World War II. By the late 1940s and early 1950s the south was producing as much cotton as it had formerly on little more than half the old acreage, and it was receiving more henome from the crop than during the 1920s. Increases in yields offset acreage declines, but the tremendous acreage decrease destroyed the former cotton belt.

In place of the cotton belt there arose seven cotton regions which, together, accounted for less than 10% of the area in the south, but produced almost two-thirds of the southern cotton crop. These regions are: the inner coastal plains in Georgia and the Carolinas; the Georgia Carolina Piedmont; the Tennessee river valley in northern Alabama; the alluvial Mississippi valley; the black wax prairies of Texas; the south Texas coastal plains; and the high plains of western Texas and

Oklahoma,

By the 1950s cotton no longer held the dominant position that it traditionally had as a southern income source. In 1930 it had accounted for about 50% of southern cash farm income; in 1944-50 it supplied about only 45% despite substantially higher prices. The basic factor involved in this change was the shift to production of livestock and other crops on acreage which higher yields had freed from cotton. Resultant diversification contributed greatly to a steady rise in agricultural income.

Cotton did not dominate the landscape in any of the seven cotton regions; in more than half of their area cotton occupied less than 15% of the total acreage during the period 1944–50. The one-crop system no longer existed. Occupance systems developed in the regions between 1944 and 1950 concentrated on cotton, the high unit-value product, plus activities which fitted both conservational rotation systems and optimum use of machinery. Beef cattle fitted these requirements well and became important in every cotton region. Each region was also noted for a second crop specialty; on the Piedmont small grains were major crops, the inner coastal plains led in tobacco and peanuts, while the Mississippi valley became a major soybean producer.

Mechanizatión of Farms.—The cotton regions became leaders in southern farm mechanization. The 1946-95 ractor increase amounted to 455:557 (1950 number of tractors: 502,858). In Arkansas, tractor numbers increased approximately 300% between 1940 and 1950, in Mississipil 400%, in Georgia 1,000%. As the number increased, the number of work animals, especially mules, underwent a tremendous decline. Infusion of machines was associated with (1) increases in pasturage, formerly devoted to supporting mules, available to support cattle and calves; (2) introduction of accessory machines, such as combines and hay balers, to utilize machine power efficiently, and adjustments in field crops to utilize the accessory machines; (3) decline in hoe-and-mule cotton farming, diversification of field crops, and reduced emphasis upon cotton; (4) decreases in rural-farm population; and (5) reappearance of many large landholdings as centrally-managed units with numerous plantationlike aspects (neoplantations). These changes were particularly pronounced after World War II.

After 1930 the majority of landowners were forced to mechanization by labour shortages. Industrial and urban growth proceeded in the south at rates greater than those for the country as a whole. Farm

workers migrated to cities and factories voluntarily in response to relatively higher urban-factory wages

Complete mechanization of cotton production became possible By the 1950s about half the cotton produced on the west Texas high plains was machine-harvested. One- or two-row picker-harvestes were available for use in humid areas; volume production of these machines began in 1948. Some machines were cheap enough for use on small cotton farms in eastern segments of the south. Pre-emergence herbicides applied by tractor-drawn machines during planting, plus postemergence herbicides to control weeds and grass in young cotton, meant that heretofore essential but laborious hand hoeing, weeding and "chopping" of the crop could be eliminated Thus hoc-culture cotton pioducion appeared doomed Mechanization was far from completed on the region's farms. By 1950 about three-fourths of them still depended primarily on animal power and more than 90% had neither hay baler, cotton harvester, corn picker nor combine.

Aspects of Diversification.—The south is important as a pro-

Aspects of Diversification.—The south is important as a producer of many agricultural products besides cotton, and both variety and volume of other products increased greatly between 1940 and 1950

The great majority of American tobacco is produced in southern Georgia and northern Florida, the inner coastal plans of the Garollans and south-central Virgnia (flue-cured cigarette tobacco areas), southern Maryland, central and western Kentucky, central Tennessee, and the Appalachian hill-lands in eastern Tennessee southwestern Virgnia (principally burley tobacco areas). Locations of these production regions were fixed by acreage-quota regulations under price-parity supports within A.A.A. legislation during the 1930s.

Peanuts are the third most important regional cash crop. The area including southwestern Georgia, northern Florida and southeastern Alabama ordmarily produced more than half the crop, followed by the Virginia-North Carolina coastal plains and the northern Texas black was prairies. Both edible and olinut varieties are produced; in the Georgia-Alabama area, hog feeding on peanuts has become widespread. Peanut producers benefit from Drice-parity supports under A.A.A. lesislation

Albama area, hog feeding on peanuts has become widespread. Peanut producers benefit from price-parity supports under A.A. legislation The northern half of the alluvial Mississippi valley became the nation's second largest soybean producing area (for vegetable oils) between 1940 and 1950. Acreage devoted to soybeans exceeded that planted to cotton, and production averaged about 13,500,000 bu. Rice production by machines predominates in east-central Arkansas, and the southwestern Louisiana-eastern Feas outer coastal blains.

pianted to cotton, and production averaged about 13,500,000 bit. Kansas, and the southwestern Louisiana-eastern Texas outer coastal plains. In 7040 and 7050 the ten top states in percentage gains in cattle population were all in the south, with Alabama, Georgia and North Carolina leading. Exclusive of Virginia and Kentucky, beef cattle increased from 11,000,000 in 1935 to about 16,000,000 in 1950, when they produced 400% more cash return than in 1925. Practically all plainslands areas expanded beef production during the 1940s; there was no distinctive regional concentration. Four major poultry producing areas developed after 1945, the Guadeloupe-San Marcos valley in eastern Texas; the upper Chattahoochee valley in Georgia, northwestern Arkansas; and northwestern Virginia. Broller chicken and meat production predominated in the first three areas; the Virginia district has been a major egg producer as well. Northern Georgia led nationally in broller output in 1951-52.

# INDUSTRIAL REGIONS

Factors Favouring Rapid Industrialization.—In large pat, urbanization was a result of major industrial and services expansions. The causes which underlay these expansions included higher consumer incomes in the region as the consequence of increased agricultural productivity and prices (the net effect of which was to create new malkets for most manufactured goods); expansion of established industries the south in response to both a larger regional market and an increasing national population; expansion of both private and public power facilities (especially electrical power) which attracted numerous industries because of low costs and availability; development of new randerials because of low costs and availability; development of new randerials processing techniques (such as newsprint manufacture from resinous southern pine) whereby underdeveloped raw materials were used for commercial use; expansion of the chemicals industries, many of whose raw materials were any present; attractive local industrial water supplies; relatively lower ad valorum and corporate income taxes than in most northern areas; plentiful labour supply (much of it not inherently skilled in manufactural processes and not unionized) and somewhat lower labour wage rates than prevailed in northern areas. Finally, the impetus provided manufacturing by World War II was enormous since both new industries and huge government supply contacts were located in the south to meet wartime exigencies. Fears that the wartime industrial expansion would collapse, harming the region's economic structure greatly when peace came, proved to be groundless.

the wartine industrial expansion would collapse, harming the region's economic structure greatly when peace came, proved to be groundless. The south of the 1930s was a rural-agrarian exporter of a few staple crops and raw materials. It was a market area for industrial and farm products most of which it did not produce itself. During the 1940s the region began to supply itself and to export some products to other areas. The remarkable progress in manufacturing was, significantly, the consequence of new developments in chemicals, mineral fuels (especially petroleum), electrical goods, metal products, and paper and apperboard industries. Older industries that also grew included textiles, wood, furniture and tobacco. The general diversification of industrial types and their widespread dispersal during the 1940s assured a

healthier economy than heretofore.

Between 1939 and 1947 the regional industrial labour force increased 50%, wages paid 10se 274% and value added by manufacture increased 244%; these were considerably greater increments than for the rest of the nation. North Carolina, Texas, Georgia and South Carolina, in that order, led in industrial employment. The textile industry, the regional manufacturing backbone, declined from 35% to 27% in proportion of total workers largely because of marked increases in employment in other industries. Textile and other low-wage industries did not expand as rapidly as did high-wage industries whose total employment was relatively small in 1939. The chemical industries, and outstanding high-wage group, undewent major expansions in the Texas-Louisiana gulf coastal area and consequently Texas threatened, in 1947, to displace North Carolina as the leading state in industrial in 1947, to displace North Carolina as the leading state in industrial employment.

In 1947 the south contained three important industrial regions the Piedmont-Appalachian area based on textiles; the Birmingham, Alahama area based on steel; and the Texas-Louisiana coastal area based

on chemicals and petroleum.

Piedmont-Appalachian Area.—Around 1875 cotton textile mills began to migrate in numbers from New England to the south,

Piedmont-Appalachian Area.—Around 1875 cotton textile mills began to migrate in numbers from New England to the south largedy'n response to lower southern wage rates, nearness to raw materials and lower taxes By 1900 the south contained 30% of the textile industry's spundles, in 1925 the region surpassed New England and by 1947 contained 77% of all US. active spindles, accounting for 84% of spindle hours operated, and consuming 87% of all US. raw cotton consumption About 70% of all US. active spindles, accounting for 84% of spindle hours operated, and consuming 87% of all US. raw cotton consumption About 70% of all looms were in the south at mid-20th century. After 1940 southern mills produced higher proportions of finer, lighter goods than formerly; the bulk of 1940-50 output was—as it had been traditionally—coarser woven goods such as sheeting, ginghams, print cloth, cotton drill, duck and denims.

Most of the rapid expansion in synthetic textiles production occurred in the south. U.S. production rose from 130,000,000 to 1,150,000,000 lb of rayon annually between 1927 and 1947, and by the latter date about 75% of the national output in six large plants. Rayon manufacture requires proximity to acids, caustics, coal and large quantities of water of great purity. Isolated plant sites, adjacent to good labour supplies, and adequately serviced by both rail and road transport are highly desirable. The extent to which the Piedmont-Appalachian area was able to supply this combination of requirements surpassed almost all other areas. Scanty data available on nylon production indicated that about 50% of the 1944 rational output was produced in the south.

All textile industries, including synthetics, ranked first in numbers of production workers a mong industries in South and North Carolina, Georgia, Virginia, Alabama and Tennessee. Textiles employed more than half the production workers in the first three states. In the first four states listed above, textile mills are located primarily in Piedmont works site is along

four states listed above, textile mills are located primarily in Piedmont towns, secondarily in cities along the fall line. In Alabama and Tennessee the Appalachian ridge and valley cities are the primary textile

nessee the Appalachian ridge and valley cities are the primary textile centres. Manufacturing employment totalled about 2,00,000 in 1947 in the south; textiles accounted for more than one-fourth of it. When textile, tobacco, furniture, lumber and paper manufactures in the Piedmont-Appalachian area were combined, they accounted for approximately 40% of southern manufacturing employment.

Tobacco manufacturing, a long-established Piedmont-Appalachian industry, employed about 62,000 workers in 1947 to produce about 72% (\$463,000,000) of the national total value added by tobacco processing. North Carolina, Kentucky and Virginia led the region in producing more than 90% of the nation's cigarettes and 30% of its cigars. The furniture industry, concentrated especially on the North Carolina Piedmont, in eastern Tennessee and in Piedmont Virginia, nearly doubled its industrial personnel in the south to a total of 75,000 nearly doubled its industrial personnel in the south to a total of 75,000 in 1947, which amounted to 25% of national furniture manufacturing employees. The south produced about 21% of the nation's furniture and related fixtures, by value, mostly in Piedmont factories.

employees. The south produced about 21% of the nation's furniture and related fixtures, by value, mostly in Piedmont factories.

The Birmingham Area.—Situated near the southern end of one of the great limestone-floored valleys of the Appalachian ridge and valley, Birmingham, Ala., is the south's Pittsburgh. Few locales are better fitted by natural advantages for iron output since all basic materials for primary production occur abundantly within less than 20 mi, of the city. The floor of the valley provides dolomitic limestone for fluxing virtually beside the blast furnaces; coal comes from the bituminous Warrior coal basin immediately northwest of the city. Southeast of the city Red mountain, a ridge extending northeastward for many miles, consists principally of Clinton (Silurian) sediments of high iron content. Several deposits of commercial quality outcrop on the western flanks of Red mountain, the largest of which—Big Seam—is 20 mi. long and contains solitic haematites averaging about 36% iron. Mining proceeds in shafts extending up to 6,000 ft. downslope. Other seams, notably the Woodstock, supply softer ore from irregular limonite deposits found in clays and gravels and extracted in open pits. Estimated local ore reserves amount to nearly 2,000,000,000 tons. During the 1940 or provided of the services of the national output.

In addition to pig iron, the Birmingham mills produce forgings, casteriated between the content of the produce of wire wester wire.

In addition to pig iron, the Birmingham mills produce forgings, castings, rails, structural steel, plate, extended soft steels such as rods, wire,

nails, bolts and rough sheets, and pipes of many types. Although steel mill employment increased about 50% in the area during World War II, it levelled off at about prewar levels during 1946-47 Consequently, the area did not keep pace with the rest of the south in industrial expansion

Gulf Coastal Chemicals Area.—This region encompasses the coastal plains in Texas, Louisiana and Mississippi. Between 1939 and 1947, production workers in chemical industries in Texas and Louisiana increased from 10,700 to 27,400, and all factory jobs increased 60% between 1929 and 1947 The population was not a highly industrialized between 1929 and 1947 The population was not a highly industrialized ne since in 1947 manufacturing employment amounted to 3,3% compared with a national percentage of 7.9 Petroleum and chemicals industries are noted for peculiarly low ratios of employees to capital investment and high wages per employee Between 1939 and 1947 slightly more than \$73,50.00,000 invested in new plants alone in this area, by about 75 chemical companies, represented about 27% of the mational investment in such plants during a period when U.S. chemical productive capacity virtually doubled The Gulf coast area was attractive to these companies because of the unusual sensitivity of the chemical industry to availability of raw materials. Petroleum, natural 2828, sall, see water, suiphur, wood nuln, grain sorchums, cane sugar. gas, salt, sea water, sulphur, wood pulp, grain sorghums, cane sugar, molasses and cane bagasse were the primary raw materials available Of these, greatest development was based upon petroleum and natural gas for production of such synthetic organics as ethylene, propylene and butylene The vast majority of all industries used petroleum or natural gas as a power source.

Between 1701 and 1751 Texas alone accounted for about one-third of the total crude oil production in the US and 21% of world output the greatest production came from the east Texas Gulf coastal field, The greatest production came from the east Texas Gull coastal field, which continues into Louisana, southern Arkansas, southern Missisippi and southwestern Alabama Large oilfields also occur in northern and western Texas, and the Texas panhandle area around Amarillo contained in 1950 the nation's largest producing natural gas deposits Crude oil production for 1951 in Texas amounted to 1,010,128,000 bbl. and natural gas output to 3,862,400,000,000 cu.ft. The crude oil output amounted to about 45% of the national total. Texas, Louisiana and Mississispi contained about 56% of the nation's proven crude oil reserves (1951), of which 47% was situated in Texas alone. Thirty-four per cent of the national refining capacity (1950) was in Louisiana and Texas, clustered principally in four areas: Houston-Texas City and Beaumont-Port Arthur, Tex., and Baton Rouge and Lake Charles, La. Corpus Christi, Tex., and New Orleans, La., were important secondary centres. The nation's two largest refuneries were situated at Baton Rouge and Baytown (near Houston).

The area's large refining capacity proved attractive to chemical

Baton Rouge and baytown (near nouscon).

The area's large refining capacity proved attractive to chemical companies concerned with synthesizing organics from refinery gases (formerly wasted), natural gas and crude oil residues. These materials are used as chemical building blocks for production of industrial alcohols, solvents, plastics, detergents, synthetic rubbers, high-octane gaso-line ingredients and certain synthetic fibres. Some of these materials were produced as end-products in the area; after initial synthesizing, chemicals essential to others were shipped from the area to processing

and finishing plants elsewhere.

In 1950 the Gulf coast produced one-fifth of the nation's electrolytic In 1950 the Gulf coast produced one-fifth of the nation's electiclytic caustic soda for use in paper mills, oil refineries and other chemical plants; the Dow Chemical company plants at Freeport-Velasco, Tex, were the leading producers. Butadiene, primary raw material of GR-S type synthetic rubber, was in production at Baton Rouge and Lake Charles, La., and Port Neches, Baytown and Houston, Tex, from gases supplied in large volume by the catalytic "cracking" petroleum process. Butane was produced from natural gas at Borger, Tex. Copolymen rubber plants, operated by established rubber companies, were situated adjacent to butadiene units in each of the foregoing centres. Streep the ether primary ingredient in GR-S rubber was were stuated adjacent to buttadene units in each of the foregoing centres. Styrene, the other primary ingredient in GR-S rubber was produced at Velasco and Texas City, Tex., from natural gas.

Anhydrous ammonia for fertilizers was in production (1950) in wartime-constructed plants at Sterlington and Lake Charles, La., and

wartime-construction at Yazoo City, Miss. These plants use natural gas, water and air as raw materials. The Houston area contained 27 chemical plants reraw materials. The Houston area contained 27 chemical plants responsible for production of alkalies, chlorine, glycerin, sulphuric acid, ammonium sulphate, sodium silicate, industrial alcohols and plastic resins. These plants and their products—the most diverse combination of chemical productions found in any Gulf coast centre—are in addition to the area's refineries. The du Pont corporation plant at Orange, Tex., produced nylon salts, methanol, formaldahyde and polythene from 60,000,000 cutf. to fautural gas delivered daily from a nearby gas field. Dow Chemical company plants at Freeport-Velasco, Tex., produced magnesium, bromine, caustic soda, vinyl chloride, glycols and other industrial chemicals from sea water, brine and natural gas. To insure an adequate natural gas supply for fuel as well as raw material. insure an adequate natural gas supply for fuel as well as raw material, the company controlled about 100,000 ac. of off and gas leases near by: Several Gulf coastal chemical centres developed into port cities/of im-

Several Guit coastal chemical centres developed into port cities of importance. Most of the Texas ports are man-made. Houston is linked to the Guif of Mexico by the Houston Ship channel, an artificial channel 58 mi. long and 34 ft. deep, whose construction was started during World War I. In 1948 Houston handled cargoes totalling more than 40,000,000 tons and rivalled New York city in volume shipped. Another artificial channel, the Sabine-Neches waterway, links Beaumont, Port

Arthur, Orange and Neches to the Gulf via a 6r mi dredged canal The volume handled by the Sabine-Neches ports rivalled that of Houston in 1948. New Orleans challenged Baltimore, Md, between 1945 and 1948 as the nation's second largest port in terms of value of cargoes, but had yet to displace the Chesapeake Bay centre. New Orleans trade expansion was based upon vigorous campaigns to capture shipments formerly handled by eastern ports and to expand traffic with Latin American nations Outshipments characterized all ports in 1948 and consisted primarily of regionally produced imperishable bulk goods such as wheat, cotton, crude oil and refinery products, sulphur, rock phosphate and bulk chemicals. Petroleum shipments provided the vast majority of cargoes from all Gulf ports except Houston and New Orleans, and predominated even in these centres. Inshipments constituted a small fraction of cargo tonnage and consisted principally of bautate unloaded at Mobile, Ala, and New Orleans, and tin ore unloaded at Texas City and Galveston, Tex.

1938); and R. B. Vance, Human Geography of the South (Chapel Hill,

SOUTH AFRICA, UNION OF. Comprising the southern part of southern Africa, which extends from the south coast of the continent to the Congo-Zambezi watershed, the Union of South Africa has an area of 472,494 sq mi. The four provinces of the Union and their areas are: Cape of Good Hope (Cape province). formerly Cape colony, 277,113 sq mi.; Natal (including Zululand), 35,284 sq.mi.; Transvaal, 110,450 sq.mi.; and Orange Free State, 49,647 sq.mi. Bordering it to the northeast is Portuguese East Africa (Mozambique); to the north, Southern Rhodesia, Bechuanaland and South-West Africa, the last-named being mandated to the Union after World War I and now administered as a part of the Union. Basutoland lies within the borders of the Union and Swazaland forms an enclave in the eastern Transvaal, but both are British territories administered by the British high commissioner and do not form part of the Union The shores are washed by the Atlantic and Indian oceans, the conventional division between the two being the meridian of 20° E.

### PHYSIOGRAPHY

Geography.-Physiographically the two primary divisions of the Union are the plateau and the marginal area which lies between the plateau edge and the coast. The plateau altitudes increase generally from about 2,000 ft. in the Limpopo trough and 3,000 ft. in the western interior to more than 11,000 ft. in the Basuto highlands, areas over about 4,000 ft. in height being known generally as high yeld and those between about 2,000 and 4,000 ft as middle veld; in the marginal areas land below about 2,000 ft. is generally known as low veld. The marginal areas normally consist of a zone of plateau slopes and a coastal zone, but in the Cape province the marginal area is split up by the folded mountains into an inner basin, between the folds and the plateau edge, known as the Great Karroo (2,000-3,000 ft. above sea level); a series of river basins within the folded area, known as the Little Karroo (1,000-1,500 ft ); and a coastal foreland between the folded mountains and the coast (sea level to 800 ft.). Between the coastal foreland and the Little Karroo stretches the Langeberg range (3,500-6,000 ft ) and between the Little Karroo and the Great Karroo the Swartberg line of ranges (5,000-7,000 ft.), the highest peak in the range being Seven Weeks Poort mountain, 7,627 ft,

The edge of the plateau is the most prominent and most continuous orographic feature in the country and is known as the Great Escarpment. It reaches its maximum altitude in the Natal Drakensberg, the highest point surveyed being Thadentsonyane (11,-425 ft.); several other points, such as Champagne Castle (11,075 ft.), Giant's Castle (10,868 ft.) and the Mont aux Sources (10,-822 ft.), are almost as high. The great height of the escarpment in this area is attributable to the strength of the Stormberg basalt, which lies at the top of the Karroo system and here attains a thickness of more than 4,000 ft. Southwestward the Great Escarpment loses height with the thinning out and final disappearance of the basalt, its highest point outside the basalt being the Compass Berg (8,215 ft.), an inclined sill of dolerite in the Sneeuwberge, north of Graaff-Reinet. Points in the Nieuwveld range, farther west, exceed 6,000 ft.; in the western part of the Cape province the highest points on the escarpment are about 5,000 ft. above sea level. To the north of Natal the highest part of the Great Escarpment is formed by the westward-dipping Black Reef quartzite, whose eastward-facing scarp is known as the Transvaal Drakensberg. The highest point in this area is Mt. Anderson (7,498 ft.), but the highest point in the Transvaal lies a little to the west in the Steenkamosberge, where Die Berg is 7,651 ft.

There are several physiographic subdivisions in the plateau. The plateau high veld stretches from the Witwatersrand in the north to the Great Escarpment in the south. The Cape middle veld extends from about Kimberley to the western edge of the plateau. To the north of the Witwatersrand lies the Transvaal Plateau basin (including the Central Bushveld basin) and the Limpopo trough, which is the lowest of all the plateau regions. The Kalahari basin lies between the eastern periphery of the plateau (high veld and Transvaal Plateau basin) and the western periphery formed mainly by the South-West Africa highlands.

Geology .- Geologically the Union consists of formations extending in time from the Archaean to Recent, the oldest rocks being those of the basal or fundamental complex, which include the older granite-gneiss formations and the most ancient metamorphosed sediments of the continent, known as the primitive formations. These are succeeded by the Pre-Cambrian systems of which the most important are the Witwatersrand system, the Ventersdorp and the Transvaal system, all of which have been greatly disturbed by earth movements and by igneous intrusions. of these the most important is the bushveld igneous complex of the central Transvaal, the largest lopolith in the world. Overlying the Pre-Cambrian are the post-Cambrian and pre-Karroo formations, including the Waterberg, Nama and Cape systems, the first two affected by faulting and by crustal flexing The Cape system is strongly folded, the high antichnal ridges of the Table Mountain sandstone being the most prominent features of the "Cape folded belt" in the south and southwest of the Cape province Overlying the Cape system the Karioo system consists of about 25,000 ft. of sediments, mostly sandstones and shales, injected with much dolerite Except in the extreme south and the east the Karroo beds have not been disturbed by folding and they are almost horizontal. Forming slightly more than half the surface of the Union the Karroo system determines to a greater extent than any other formation the surface features of the country. Because of the horizontality of the beds, the alternation of sandstone and shale and the widespread outcrops of dolerite, the type of surface associated with the Karroo formation is tabular, wide expanses of plain being broken by frequent occurrences of tafelberge (mesas), tafelkops (buttes) and spitskoppies (with pointed summits) Post-Karroo formations, covering comparatively small coastal areas and synclinal valleys in the Cape folded area, include Cretaceous and Tertiary marine beds, fluviatile conglomerates and the widespread Cretaceous to Recent conglomerates, limestones, sandstones and sands of the Kalahari basin, only the extreme southern end of which falls within the Union. (I H. Wn)

Climate.—The climate of South Africa is warm, temperate and dry except in the mountains and the coastlands of Natal and Cape province. The main controlling factors are the subtropical situation and the altitude of the plateau. Except in the southwestern and southern Cape province the rain falls in summer, often in heavy convectional showers occasionally accompanied by hail. In the region of winter rainfall in the southwestern Cape, however, the rains are associated with travelling barometric depressions of the westerly wind belt. In a country which is so large and in which altitude ranges from sea level to more than 10,000 ft., large variations of climate are to be expected. But the most striking is the decrease in rainfall from east to west; the western half of the country is semiarid passing gradually into desert which is found

near the mouth of the Orange river.

The warmest and wettest region is the subtropical coastland of Natal below 2,000 ft. in height, extending from Kosi bay southward to the Cape province. The rainfall is 45-50 in. in northern Natal but decreases to 33 in. at Port Elizabeth. The wettest month is March, at the end of summer. In summer the coastal region is uncomfortably warm; the mean January temperature is about 75° F. and the range between day and night is about 12° F. Relative humidity falls to about 65% in the afternoon. But in the winter the climate is close to the ideal for human comfort; at Durban the mean July temperature is 65° F. and the daily range 16° F. The coast is windy, and while the regular and strong sea breezes in Natal give some relief from the summer heat the persistent winds farther south are a disagreeable feature of the climate. East London, with a mean velocity for the year of 15 m.p.h., is one of the windiest places in South Africa.

Westward, on the eastern slopes of the plateau, climates vary with altitude and exposure. Exposed mountain slopes are misty and wet, while the sheltered valleys (e.g., the Pongola, Umfolozi, Tugela and Great Kei) are much drier. Valleys and depressions are liable to extreme temperatures—hot in summer and cold in winter. Mean summer maxima in the Tugela and Buffalo valleys exceed 90° F. and the range from summer maxima to winter minima is about 50° F. In Natal and the Cape severe frosts are fre-

quent, at Nottingham Road (4,700 ft.) in July the minimum temperature falls below 27° F. on three nights out of five But in the Transvaal the plateau slopes have milder winters and the freedom from severe frosts makes these areas important producers of winter clops In summer, however, this region, which merges into the low veld adjoining Mozambique, is uncomfortably hot At Komatipoort the mean January maximum is 92° F. and the mean July maximum 70° F.

The main climatic features of the plateau are low rainfall, plenty of sunshine and large seasonal changes in weather. Summer is warm and rainy and winter is cool and almost rainless. At Johannesburg the mean rainfall is 33 in, the wettest month being January, with 6 in , and the driest July with 0 5 in. The highest rainfall occurs in the mountains of the eastern escarpment-e.g., Woodbush, Forest, 68 in .- but over most of the Transvaal and Orange Free State the rainfall is between 20 and 30 in. (at Pretoria 31 in., Pietersburg 18 in , Bloemfontein 21 in., Standerton 30 in.). The 20-in isohyet (line of equal rainfall) lies close to the 26th meridian, and the semiand part of the plateau, including the western Orange Free State and the central and western part of Cape province, lies to the west of this isohyet The high veld is moderately cool; Johannesburg (5,750 ft.) has a mean January maximum temperature of 80° F, and the temperature seldom rises above 85° F. Fortunately the occasional high temperatures are associated with very low relative humidity and the heat is not unbearable. Frosts occur between April and September and severe frosts occasionally from June to August. (Mean July minimum at Johannesburg, 38° F) The western part of the plateau is lower and in summer hotter than the high veld. (At Kimberley the mean January maximum is 91° F.) Afternoon temperatures are usually close to 90° F. and temperatures above 95° F. can be expected oc-casionally from October to February. The hot season ends in casionally from October to February. March and from then till October the climate is pleasant and comfortable. The days are warm and dry and the dry atmosphere accounts partly for the large diurnal range of temperature (at Kimberley the mean July maximum is 66° F. and the minimum 37° F.). This pleasant winter weather is interrupted once or twice a month by outbreaks of cold air in strong southerly winds, which sweep across the plateau. The cold air has a high lapse rate and so, while the temperature in the coastal regions over which it passes may not be exceptionally low, the plateau may suffer from severe frost. The lowest temperatures on record are: Standerton (5.004 ft.) 9° F., Middelburg (4,746 ft.) 11° F. and Bloemfontein (4,678 ft ) 12° F.

From the northwest coast of the Cape province desert spreads inland in the valley of the Orange river and Namaqualand. The coastal strip cooled by the Benguela current is quite distinct climatically: mean temperatures vary little throughout the year (Port Nolloth, mean January maximum 67° F. mean July maximum 64° F.), and the low cloud and fog characteristic of coldwater coasts is nearly always there-a uniform layer of stratus cloud from which drizzle is falling covering the whole sky a few hundred feet above the ground. It forms at night and usually is dispersed by the sea breeze before noon. In this coastal desert the highest temperatures occur in the winter in short hot spells when "Berg" winds blow seawards from the interior. Similar in some respects to the foehn and Chinook, the berg winds are formed by subsidence in the atmosphere. Though they affect all parts of the South African coast they are remarkable on the west coast because of the great difference between the temperature of the berg wind and the normal temperature.

Climatically the southwestern and southern Cape province are distinct from the rest of the country. Winter is the rainy season and in the southwestern Cape the summer is dry. But the southern Cape gets summer rains too and is the only part of the Union with an all-season rainfall. In the southwestern Cape the mountains are responsible for variations in both temperature and rainfall. Near Cape Town the mean rainfall is 25 in. Rainfall decreases northward, Saldanha bay, about 100 mi. from Cape Town, receiving about 10 in. At Cape Town the mean January temperature is 70° F. and the mean July temperature 55° F., the mean daily ranges being 20° F. and 15° F. Both winter and summer

are characterized by strong winds—in winter the strong northwesters which often bring rain, and in summer the "Cape southeaster" which sometimes blows with gale force for two or three days at a time. (S. P. Jn.)

Vegetation.—Five vegetational types can be recognized in the Union: (1) forest, (2) savannah, (3) grassland, (4) sclerophyll

and (5) semidesert and desert.

Natural forest occurs where there is the perennial availability of adequate soil and atmospheric moisture. In few parts of the Union do such conditions obtain, and where they do the effects of fire and human exploitation have reduced the areas, so that at present only about 0.25% of the country is covered by natural forest. Three main types can be recognized: temperate, subtropical and montane. The largest area of temperate forest lies between the south coast, to the west and east of Knysna, and the Langeberg orographic line (the Outeniqua mountains). This area, which is generally known as the Knysna forest, contains almost entirely evergreens, the tallest and economically most important trees being the yellowwoods, Podocarpus spp., which are sometimes 150 ft. high. Other valuable trees include the stinkwood (Ocotea bullata), the sneezewood (Ptaeroxylon obliquum), the black ironwood (Olea laurifolia), the white ironwood (Toddalea lanceolata), the Cape beech (Myrsine melanophloeos), the assagar (Curtisia faginea) and many others.

Much smaller areas of temperate forest occur on the southern slopes of the Winterberg-Hogsback-Amatola escarpment and in the interior of Natal. Subtropical forest occupies a narrow coastal belt stretching from the eastern Cape province through Natal and Zululand into Mozambique. The altitudinal limit is about 800 fit, the most common trees in the dense bush and evergreen forest being of the genera Albizzia, Protorhus, Sclerocarya, Trichilia and Ficus. Formerly the Cape box (Buxus maconani), the Cape mangany (Trichilia emetica) and the Cape ebony (Heywoodia luceus) flourished in this forest zone but they have almost all been cut down for timber. Palms such as the wild date palm (Phoenix reckinata), the ilala palm (Hyphaene crimta) and the wine palm

(Raphia vinifera) are found in this zone.

The montane forest occurs on some of the east-facing escarpments of Natal and the eastern Transvaal. The largest areas are the woodbush, to the east of Pietersburg, and the Entabeni forest, on the southern slopes of the Soutpansberge, to the east of Louis Trichardt. The heavy rainfall and frequent mists brought in by the easterly winds are responsible for these occurrences.

2. The savannah occupies the eastern and northern parts of the Transvaal, extending westward into the Kalahari basin and in a narrow belt southward as far as Port Elizabeth, with outliers in the Little Karroo. Of the mixed type, the savannah in places has a close association of trees almost resembling a forest; elsewhere it opens out to parkland and in places to tree steppe. In the eastern part of the Union the most common trees are acacias, with aloes and euphorbias in the drier areas. The most common grasses are of the genera Themeda, Panicum, Rhynchelytrum, Setaria, Pennisetum and Chloris. In the northern Transvaal the baobab (Adansonia digitata) is associated with the acacias and in the middle Limpopo valley the dominant tree is the mopane (Colophospermum mopane).

In the central bushveld basin of the Transvaal the mixed character of the savannah is most marked, for both evergreen and deciduous types are represented, including the genera Faurea, Burkea, Protea, Terminalia, Combretum, Rhamnus, Rhus and many others. In the southwestern Transvaal and northwestern Orange Free State the Kalhanti thorn veld is dominant, the most characteristic tree being Acacia girafae, with which are associated A. karroo, A. detimens, A. dulcis and many other acacias. Other common trees include Burkea africana, Terminalia sericea and Bosia albitrunca, and the grasses include the short and tall Bushman grasses, Aristida ciliata and A. uniplunis, with Dantonia suffrescens on the dune crests.

3. The grasslands lie mainly in the summer rainfall area to the east of the 15-in. isohyet and so occupy almost all the eastern portion of the plateau high yeld, the high yeld and middle yeld of Natal and the eastern Cape province. From the pastoral point

of view three types of grassland can be recognized. In the west a "sweet" veld type predominates in which the grasses remain palatable and nutritious throughout the year. In the east the grasses are mainly of the "sour" type, nutritious during the first two or three months of growth and thereafter becoming unpalatable and indigestible to animals. In an intermediate position lies a mixed type of veld in which both sweet and sour grasses mingle. On the plateau the most common species are of the genera Themeda and Cymbopogon, with Hyparrhenia, Tristachya, Trichopteryx, Digitaria and many others represented. Below the escarpment, in the Natal and Transkeian high veld, the main grasses are of the genera Hyparrhenia, Sporobolus, Setaria, Tristachya and Themeda.

- 4. The sclerophyll covers most of the southwestern Cape province, where the climate is of the Mediterranean type, with winter rain and summer drought. The sclerophyll bush occurs between sea level and about 3,000 ft. where the rainfall is between about 20 and 30 in. Large bushes, mostly shrubs five to eight feet high belonging to the Proteaceae, are generally interspersed with small woody plants and geophytes including an abundance of those of the Restionaceae; in other areas an intermediate layer occurs consisting of small shrubs of the Compositae, Ericaceae, Rustaceae and many others.
- In the more humid areas the wet schlerophyll bush is more luxuriant, consisting mainly of a dense growth of bushes up to ten feet in height, in which the most common genera are Berselia and Erica. On the mountains at altitudes of more than 3,000 ft. mountain bush is composed of smaller bushes which often assume a prostrate habit as a protection against the wind. Along the border of the semidesert zone another type can be recognized—the dry schlerophyll bush, a more open association than in the wetter areas, the low bushes having small, dry, flat leaves; succulents are often found mingled with the bushes. There is a general absence of trees in the sclerophyll area except in the kloofs and ravines of the high mountain ranges.
- Semidesert and desert vegetal types occur where the rainfall is less than about 15 in, in the summer rainfall area and about 10 in. in the winter rainfall area. The most common vegetal form is the desert shrub, which is of the woody type in the moister areas and of the succulent type in the drier. In the driest parts of the Karroo, where the annual rainfall is about five inches, the most common forms are low succulent bushes rarely more than eight inches high together with tiny shrubs with ericoid leaves and many species of Mesembryanthemum. In the western Karroo the two most common bushes are the kraalbos (Galenia africana) and the yellow milk bush (Euphorbia mauritanica), while numerous geophytes burst into activity during the short wet season. Farther east the succulents are taller and include bushes of Euphorbia, Cotyledon, Aloe, Crassula, Mesembryanthemum and Portulacaria. In the eastern Cape province Aloe ferox is abundant, as are three or four species of Euphorbia, including the noorsdoorn (E. coerulescens), an important stock feed in times of drought.

The second type of desert shrub, the woody bush, is the Karroo bush proper, of which a taller mountain type can be recognized and a smaller type which covers most of the flat country. The smaller shrubs are perennial woody bushes about 3 to 12 in. high, with very small leaves and relatively large spreading roots. The most common are various species of Pentzia, such as the gansies (P. wirgata, P. incara, P. globosa), the sweet resin bush (Euryops multifidus), the bitter karroo (Chrysocoma tennifolia), the gannas (Salsola spp.) and the saltbushes (Atriplex spp.).

After rain annual grasses spring up, often almost concealing the bushes, but they die in times of drought. The karroo bushes, however, can survive droughts of nine or ten months' duration, after which seedlings spring up when the next rains occur.

In the desert areas of the northwest coastal zone where the rainfall is less than about five inches, a zone of succulents just behind the coast is made possible by the frequency of mists. The desert zone is continued into the South-West African namib and up the Orange river valley into Little Bushmanland. In the rocky areas of Little Namaqualand tall succulents occur such as the elephant's trunk or halfman (Packypodium namaquamum), the

kokerboom (Aloe dichotoma), the spekboom or fat tree (Ceraria namaquensis), the poison tree (Euphorbia virosa), the Bushman's candle (Sorcocaulon burmanii) and many others. (J. H. WN.)

Fauna.-Zoologically South Africa belongs to the Ethiopian region and is characterized by the absence of bears and deer and by the presence of a great variety of antelopes, which range in size from the diminutive blue duiker to the eland. Some of the more strictly tropical forms are unrepresented, such as the gorilla, chimpanzee and many of the parrots. Some animals, as for example the lion, crocodile and some antelopes, have a continuous distribution from the Sudan, along the East African corridor between the great equatorial forests and the coast belt down to South Africa. On the other hand the country may be regarded as a distinct subregion of the Ethiopian area because of a number of forms which are peculiar to it. Among these are the springbok, black wildebeest, the long-tailed sugar bird, which appears to have a distribution closely related to that of the Proteaceae, and a great variety of insects, adapted to the Cape flora. Since the white man entered the country with his rifle, his enclosures and his domestic animals, the numbers of the larger native animals have been enormously reduced. A few species such as the quagga have become extinct. Several species of buck survive only in a semidomesticated state on some of the large farms or in game reserves. The white rhinoceros, which occurs about the sources of the Nile and which used to be common in the area between the Zambezi and the Orange rivers, is now represented only by a few individuals in the Umfolozi game reserve of Zululand. The elephant still survives in the Knysna forest, the Addo bush and the Kruger National park and in Bechuanaland, and a herd of mountain zebra is preserved in Cape province.

Of the rodents there are about 150 species, including squirrels, hares and porcupines. Two species of Insectivora—the golden mole and the elephant shrew—are peculiar to South Africa. The Nomarthra and Tubulidentata include the scaly anteater and the aardvark, or ant bear, the structure of whose teeth (molars) has on analogy among the mammals. Several species of whales are caught in South African waters. The primates are not well represented, but monkeys are found in the forests and baboons are comnon in nearly all the mountainous areas. Of the Carnivora the leopard is still fairly secure in some of the mountain kloofs; lions are confined to the northern Transvaal and the Kruger National park. Several of the smaller Felidae—wildcat, lynx, spotted serval, etc.—are moderately numerous. Hyenas are becoming scarce, but the Canidae are still well represented by the black-backed and striped jackal and the wild, or Cape, hunting dog.

Over a thousand species of birds are known, including migrants such as the European swallow, red-backed shrike, white stork, curlew, etc. Parrots and hornbills are found from the tropics to Damaraland on the west, and on the east through Natal to the Knysna forests. The jackass penguin, which breeds in large numbers on the islands of the south and west coasts, represents an antarctic element. Eagles, kites, falcons, harriers, hawks and owls occur. The secretary bird, with its long legs and terrestrial habit, is related to the eagles and hawks and is protected because of its reputation as a snake killer. It is peculiar to South Africa. Among the birds which are shot for sport or food are the francolins (locally known as pheasants and partridges), guinea fowls, sand grouse, ducks and geese. The ostrich still exists in the wild condition in unenclosed parts of the country. The common European starling is rapidly spreading about Cape Town and in the coastal parts of Natal; the Indian mina is well established and is pushing away some of the native species.

The reptiles include more than 350 species. The crocodile does not occur south of the Kunene and Tugela rivers. Tortoises and especially lizards are numerous. Snakes are represented by 125 species. Among these are the puff and night adders, cobra, python and the swift and deadly mamba (Dendraspis angusticeps).

There are 200 species of fresh-water fish. By far the commonest are representatives of the carp family, known in South Africa as barbel. The tiger fish (Hydrocyon lineaties) is the finest indigenous sporting fish and occurs in the Komati and Crocodile rivers. There is only one native species of eel; it is confined to the rivers

flowing into the Indian ocean. Brown, rainbow and Loch Leven trout have been acclimatized and many rivers in the cooler parts of the country are well stocked. In Natal they do well above 4,000 ft. South Africa has many varieties of scorpions and spiders. Of insects, it is estimated that there are at least 40,000 species. Those of the northeastern and eastern districts have affinities with central Africa. Mention can only be made of the mantis, or Hottentot god, the white ants or termites, which are often destructive of timber and trees; of the bees, including honey bees, which are common; of several types of mosquitoes, including the anopheline mosquito; and the tsetse fly (Glossim).

#### HISTORY

Portuguese Pioneers .- Whether or not the Phoenicians sailed around Africa as claimed by Herodotus, southern Africa was unknown to the Greeks and the Romans and to Europeans before the 15th century. Then, largely as a result of the patronage of Prince Henry the Navigator (1394-1460), Portuguese mariners steadily pushed down the West African coast until in 1488 Bartholomeu Diaz de Novaes rounded the Cape of Good Hope and in 1498 Vasco da Gama, in a flagship of 120 tons, 80 ft. long, reached the objective, India. Thereafter the Portuguese gained maritime supremacy in the Indian ocean and used it to exploit the Asiatic spice trade and, less effectively, the East African gold trade. But, though they colonized Angola and Mozambique, they made no settlements as far south as what is now the Union of South Africa, regarding its resources as negligible and its inhabitants as too primitive for commercial or evangelical effort. Throughout the 16th century, therefore, South African waters were often Praversed by Portuguese fleets, but the only civilized people who spent much time ashore there were the survivors of the many ships that were wrecked on the coast.

# DUTCH FOUNDATIONS

The Trading Companies.—By the end of the 16th century Dutch and English seamen had also begun to trade with Asia by the Cape route. They found it desirable to pause for refreshment, the death rate on the long voyage being often as high as 50%; so during the first half of the 17th century they usually stopped at St. Helena, the Cape or Mauritius. In 1615 the English tried vainly to form a settlement at the Cape with ten felons reprieved from the hangman's nose, and five years later two English captains made the empty gesture of annexing all Africa for King James; but it was St. Helena that eventually became the main port of call for the English company.

Meanwhile the Dutch East India company outstripped all rivals and obtained a virtual monopoly of the East Indian spice trade. For several decades Dutch ships made a practice of putting into Table bay to take in fresh water, to barter meat from the Hottentots and to find the latest information about the affairs of Europe or Asia in dispatches they left one another under inscribed stones. Then in 1647 Leendert Janssen was shipwrecked in Table bay with the crew of the "Noord Haerlem," and after his return to the Netherlands he presented a report advising the company to found a permanent refreshment station at the Cape. Largely because the Anglo-Dutch war of 1652-64 was imminent, the directors eventually agreed; three ships were to take out materials for building, seeds and implements, and 90 men were to build a fort and develop a vegetable garden.

Jan van Riebeeck.—To command the expedition the directors chose Jan van Riebeeck. or Riebeek, a doctor by training, who had already had six years of commercial experience with the company. He landed at the Cape on April 7, 1652, and remained ten years, during which time droughts, floods and pests, indiscipline among his subordinates and thefts by the Hottentots often brought the settlement to the brink of disaster. Burit survived; a timber-and-sod fort was built, the coast line was charted, the interior was explored, and a belt of land extending about eight

miles from Table bay to Wynberg was brought under cultiva-

However, the Cape did not become the simple outpost which the directors had had in mind At that time Hottentots, pastoral nomads loosely organized in small tribes, occupied most of the coastal regions of South Africa as far east as Natal. The Cape peninsula had been used by two such tribes, who regarded the Dutch as intruders in their domain, especially when it became apparent that they were not birds of passage but were building fortifications and extending their area of cultivation. The Dutch bartered with the Hottentots for sheep and cattle and from time to time the Hottentots stole them back again. Van Riebeeck calculated whether he was strong enough to use force, but when the directors cautioned him to do no such thing he fell back on the idea of confining the settlement within a palisade this early stage in South African history it was not possible to keep the races completely apart, because the Dutch continued to barter with the natives. Van Riebeeck also initiated two experiments which had far-reaching consequences. At first all the work of the station was done by the company's servants, but in 1654 a few slaves were imported and more came in 1658 and thereafter. The second experiment started in 1657 when the company, hoping it would save money if corn were grown and stock bred by unpaid freemen instead of by paid employees, freed nine men from their contracts and gave them 30-ac. farms along the Liesbeeck valley at Rondebosch, where they were to produce corn and stock and sell them to the company at the company's prices. So Van Riebeeck left behind him an embryonic colony of settlement which used slave labour and was confronted with a "native problem."

Immigration and Expansion .- In 1662 the Cape contained only about 250 white persons, of whom nearly half were company servants, and in the next few years there was little increase. But during the governorships of Simon van der Stel (1679-99) and his son W. A. van der Stel (1699-1707) the company made its one serious effort to encourage immigration. In 1707 a census showed a white population, other than company servants, of 1,779 men, women and children, owning 1,107 slaves. This was a slow rate of progress compared with that of the English colonies in North America. Nevertheless, the Afrikaner people of today are descended for the most part from those who were enumerated in 1707. These were company servants who had taken their discharge at the Cape and people who were sent out to settle. Most of them were of Dutch and German stock. There was also a small but significant group of rather fewer than 200 French Huguenots who, after the revocation of the Edict of Nantes in 1685, went to Holland and then were sent to the Cape. As a matter of policy the company scattered the Huguenots among the other settlers, and within little more than a generation they became fully assimilated, discarding the French language and even pronouncing their names in the Dutch manner. The area of settlement expanded with the population-to Stellenbosch beyond the sandy Cape flats (1679) and then to the Berg river valley. To meet the needs of local administration a general purposes official (landdrost) was appointed to Stellenbosch in 1685; sitting with four local freemen (heemraden), he was given jurisdiction in minor civil cases. Nearly all the company servants, however, lived in Cape Town, where the governor and his chief subordinates formed a council of policy which issued regulations for the colony, subject to the overriding authority of the governor general and council of the Indies in Batavia and the directors in the Netherlands.

From the first the freemen had fretted at many of the regulations, which imposed restrictions and taxes on internal trade; for example, the rights to deal in much local produce, including cattle, were auctioned annually to contractors, as well as the rights to retail imported goods. Furthermore, by the end of the century the Cape was producing more wine, brandy and corn than was consumed locally and by passing ships, and there was little opporunity for export.

What was particularly galling to the freemen was the tendency of the officials to farm and trade on their own account, using their uthority to make sure that their own produce did not remain nsold. This led to an outcry against the governor, W. A. van der

Stel, who embarked on large-scale farming operations and cornered the market so successfully that some malcontents, including the Huguenot diarist Adas Tas. sent a petition to the directors, who recalled Van der Stel in 1707. But the underlying cause of the discontent—the commercial policy of the company—was not remediad

The Evolution of the Afrikaner People.-The company had no vision of a New Netherlands in South Africa and sponsored no immigration schemes after the time of the Van der Stels. Nevertheless, during the 18th century a New Netherlands of a sort was arising from the materials present. The white population grew. mainly by natural increase, to about 15,000 in 1795, by which time they regarded South Africa as their only home and spoke a language, Afrikaans, which deviated from the language of the Netherlands. Those who lived in Cape Town-the only port and the only real town in the colony-were mostly traders and innkeepers. In the southwestern part of the colony, near Cape Town, were the corn and wine farmers, or boeren, some of them proprietors of large estates run by slave and Hottentot labour Beyond them were the trekboeren, about half the total white population. The trekboeren were seminomadic, many of them completely nomadic, pastoral farmers. Most of the land they occupied was unsuitable for cultivation; moreover, the market for agricultural produce was glutted and slaves did the skilled work There was, therefore, nothing to keep the inof the colony crease of the white population in the southwestern Cape and much to encourage them to disperse and become self-sufficient pastoral farmers. The way was paved by W. A. van der Stel, who, unlike his father, allowed freemen to concentrate on stock farming, Within a few years it became possible for any freeman to take occupation of 6,000 ac. or more of land and treat it as his property, paying the company a small annual licence. The result was a continuous expansion of the frontiers of white settlement. In the north the trekboeren were slowed up by aridity and finally stopped near the Buffels river about 1760. In the east they advanced along either side of the and Great Karroo until in the 1770s the two streams of pioneers began to mingle beyond it in the vicinity of what became Graaff-Reinet, about 400 mi. from Cape Town. Thus a few thousand white persons scattered over an area about twice as large as England. Their simple needs were met by their stock and by hunting and by travelling traders who bought their sheep and cattle for the Cape Town market and sold them a few imported goods. The company did little for them beyond establishing courts of landdrosten and heemraden at Swellendam (1745) and Graaff-Reinet (1785). From time to time officials expressed concern that the isolation of the trekboeren was causing them to degenerate. But although all the trekboeren were extreme individualists and some were ruffians, most of them contrived to preserve a sound domestic morality, a smattering of literacy and a respect for their religion, a rather strait Calvinism.

Slaves, Hottentots and Bushmen.—During the 18th century the slaves, the Hottentots and some of the Bushmen (q,v) were beginning to interbreed with one another and with Europeans to produce the community now known as the Cape coloured people. Although few slaves were imported, the slave population outstripped the white to number nearly 17,000 in 1795. Negroid types from the west and east coasts of Africa predominated, with Malays from the East Indies forming an important minority. There was a considerable amount of extramarital miscegenation between white men and slave women. Most of the slaves were the property of the agricultural farmers, for whom they formed the main labour supply. Others were owned by the company and the Cape Town burghers, a few by the trebboeren. The treatment of the slaves, which had at first been fairly mild, tended to deteriorate, and the 1754 slave code was a stiff one.

The nearest approach to a Hottentot war had taken place in the 1670s. It was smallpox that took the heaviest toll of the Hottentots, especially a shattering epidemic in 1713. After that, as the trekboeren advanced into their territories, the surviving Hottentots lost their land and their cattle, their only means of an independent existence. Many were reduced to a status not unlike serfdom. forming the main labour supply of the trekboer, whose

simple demands they were able to satisfy. Others withdrew beyond the frontiers of white settlement to maintain a more or less Independent existence until the next century.

There was a certain amount of miscegenation between white men and Hottentot women, although intermarriages had been unlawful since 1685. The offspring were usually disowned by their fathers and became known, bluntly, as Bastards; some entered into service, others retreated before the advancing trekboeren, leading trekboer lives themselves.

The small Bushmen were still more primitive than the Hottentots. Before white settlement began they had been driven into the more arid and mountainous parts of South Africa by the Hottentot and African tribes. But, though every man's hand was against them, they contrived to make hit-and-run raids to get sheep and cattle for food, and, if cornered, they were able to kill human beings with their poisoned arrows. As the trekboeren in turn-began to enter Bushman country and to suffer from their raids they organized Boer commandos to hunt them. Toward the end of the 18th century several Bushmen bands made a prolonged stand, operating from mountain fastnesses along the northern fringes of the area of white settlement; but the commandos gradually cleared them out, killing 2,500 Bushmen and capturing 650 in the decade ending in 1795. Those captured were children who were taken into service.

Their experience with slaves, Hottentots and Bushmen had important and enduring effects on the racial attitudes of the Afrikaner people. Most of the nonwhites they came into contact with were at so low a cultural level that the Afrikaners tended to think of themselves as innately superior. Their response was not merely hostile, however, because they all—Capetonians, agriculturalists and trekboeren—came to depend on the use of nonwhite servants.

African Opposition and Economic Discontent.-Before the last quarter of the 18th century the trekboeren had not been seriously impeded by human obstacles. Then, however, they came up against formidable opposition. There were two main groups of African (Bantu-speaking) tribes in southeastern Africa: the Nguni group, who inhabited the well-watered coastal strip between the mountains and the Indian ocean; and the Sotho group, on the plateau. These Africans were more numerous and more advanced than the Hottentots; they were organized into larger tribes and, though they too were primarily pastoralists and hunters, they also practised a rudimentary type of agriculture. While the trekboeren were moving eastward in search of new pastures, some of the Nguni tribes were moving westward toward them from Natal for the same purpose. By 1700 the Xosa tribe in the van had reached the Great Kei river; by 1750, the Keiskama. Boer hunters made contact with the Xosas and bartered ivory and cattle from them. The company vainly tried to prevent such contacts and delay the convergence of the Boers and the Xosas by issuing proclamations prohibiting barter and defining limits beyond which the Boers were not to go. When the governor, J. van Plettenburg, toured the frontier in 1778 he found that the leading Boers were already intermingled with the leading Africans in the vicinity of the Fish river.

A long series of frontier "wars" followed-basically struggles for possession of the land. The first fighting took place in 1779-81 and was sufficient to show the Boers that they faced tough opposition. They therefore appealed to the company for aid; although a landdrost, M. Woeke, was appointed to Graaff-Reinet in 1785, no troops were sent. Woeke's life was soon made intolerable by the Boers, and in 1793 he was superseded by H. C. D. Maynier. Further fighting broke out in that year and again the result was inconclusive. The Boers were disgruntled. For nearly a century they had been left by the company to make their own terms with man and nature, and when at length they had asked for help all they received was a government official who not only failed to defeat the Xosas but also allowed Hottentots to come to his court with complaints against them. In 1795, on the eve of the British conquest of the Cape, they drove out Maynier and declared Graaff-Reinet to be a republic. But the name "republic" was a euphemism: in fact there was anarchy at Graaff-Reinet. Similar events took place at Swellendam, where another "republic"

came into being.

Meanwhile there was trouble in the southwestern part of the colony also. The company had maintained rigorous commercial restrictions, together with a system of government that gave the colonists practically no voice in the determination of policy. The trekboeren had managed to escape most of the effects, but the restrictions had always borne heavily on the agricultural farmer who had produce to sell and on the Cape Town man who lived by trade. In the 1770s, which were lean years, the discontent came to a head with the organization of the Cape Patriots movement, which had some connections with the anti-Orange Patriot party in the Netherlands (see Holland). A petition was drawn up criticizing many of the officials and asking for full burgher representation on the council of policy and the right to trade freely throughout the company's possessions. When it was laid before the directors in Amsterdam, their only response was to dismiss the official who was most roundly criticized—the fiscal, W. Boers.

In 1784 a second petition was taken above the heads of the directors to the states-general of the Netherlands. This time the colonists were given equal representation with officials on the court of justice, but not on the council of policy, and the right to trade with the company's possessions—a right that was nullified by the conditions that were attached. By then, however, the disaffection had subsided because the American War of Independence had brought a large French garrison to Cape Town to help the Dutch to defend it against the British, and the garrison provided an abnormally large market for Cape produce and brisk business for the traders and innkeepers. In the early 1790s bad times came again as the company, trying desperately to stave off bankruptcy, made a final effort to make the colony pay its way. The garrison was reduced, public works were suspended and-the last strawnew taxes were imposed. So, when the British invading force arrived in 1795, it found depression in the west and rebellion in the east. The company had never done much for the white colonists and still less for the nonwhite races.

## SOUTH AFRICA DIVIDES (1795-1870)

The British Conquest .- The Cape was captured by a British naval and military force in Sept. 1795, nominally on behalf of the prince of Orange, who had taken refuge in England from the Dutch republicans. In their struggle with France the British considered it essential not to let the Cape fall into enemy hands, and until the peace of Amiens a hold was kept on it for strategic reasons. The British tried to conciliate the Afrikaners, and by abolishing the restrictions on internal trade and maintaining a large garrison they caused an economic revival in the southwestern part of the colony. On the eastern frontier, on the other hand, the British were no more successful than their predecessors. Although the republics of Swellendam and Graaff-Reinet soon submitted to the new government, anarchy developed in Graaff-Reinet again in 1799, after the arrest of a prominent trekboer, A. van Jaarsveld, on a charge of forgery. Not only the Xosas but also many of the Hottentot servants of the Boers made the most of the opportunity created by the divisions among the whites and caused havoc as far west as Knysna. The British general F. Dundas patched up a truce; but H. C. D. Maynier, appointed resident commissioner of the two eastern districts, failed to satisfy the trekboeren, who rebelled again in 1801, when once again their Hottentot servants joined with Xosa tribesmen to harry the farms over a wide area.

The eastern districts were therefore in turmoil when in 1803 the Cape was handed back under the treaty of Amiens. By this time the company was dead and the Dutch government—the Batavian republic organized by the French in 1795 after their conquest of the country—succeeded to its charge. J. A. de Mist, the commissioner general, and Gen. J. W. Janssens, the governor, tried to restore the morale of the Boers and showed a considerable understanding of the problems of the country; but these men did not stay long enough to consolidate their reforms, for in 1806 the British sent out another force to recapture the Cape from Napoleon's Dutch allies. Janssens lacked the means to put up much resistance and once more the colony passed into the hands of the

British, whose title was confirmed in 1814 as part of the general peace settlement

British Policy, 1806-36 .- Until 1823 British policy was cautious and conservative. Although the governor had autocratic powers, the Afrikaners were used to that. Moreover, their Roman-Dutch law was retained and local administration remained as of old in the hands of landdrosten and heemraden, most of them Afrikaners. These were comparatively prosperous years. The southwestern farmers profited from their access to British markets, where their wine sold well thanks to a substantial tariff preference. Elsewhere, however, extensive pastoral farming remained the norm. Nevertheless, the British did introduce some changes in these years. They appointed more landdrosten. In 1809 they promulgated a code for the treatment of Hottentot servants, who were to be employed only under written contracts registered at a landdrost's office and were given legal protection against ill treatment; on the other hand, they were not to be allowed to leave their employer's farm without a pass signed by the employer. From 1811 onward high court judges, who had previously sat only in Cape Town, made annual circuits to hear cases in all the dis-

Mild though these reforms were, they caused trouble. There was much grumbling in 1812 when the judges on circuit in the easte n districts tried a number of Afrikaners on charges of ill treating their Hottentot servants. Three years later a trekboer, F. C. Bezuidenhout, opened fire on a party that had come to arrest him for repeatedly ignoring his landdrost's orders to answer a similar charge; in the skirmish Bezuidenhout was killed, whereupon his brother proceeded to organize opposition to the government; but the Slagtersnek rebellion soon ended when about 60 rebels were rounded up and tried, and five ringleaders were hanged.

The British also brought superior force to bear against the Xosas on the eastern frontier and thus started the process of the conquest of the African tribes. In 1811 British regular troops and Boer commandos drove the Xosas back to the eastern side of the Fish river, and in 1819 to the eastern side of the Keiskama.

In 1820, 5,000 British settlers were brought out and placed on 100-ac. lots in the Zuurveld, on the western side of the Fish, at a cost of £50,000 to the British government. The 1820 settlers did not, however, form the human barrier that was intended, because the land was not suited to agriculture; within a few years most of them had abandoned their lots and become townsmen in Port Elizabeth and Grahamstown. Others became traders among the African tribes to the east. Those who stayed on the land eventually made good by producing wool for export to England, especially when large farms came onto the market at the time of the Great Trek. This was the first subsidized immigration scheme since the 17th century, and the 1820 settlers were the first white immigrants who were not assimilated by the Afrikaner people.

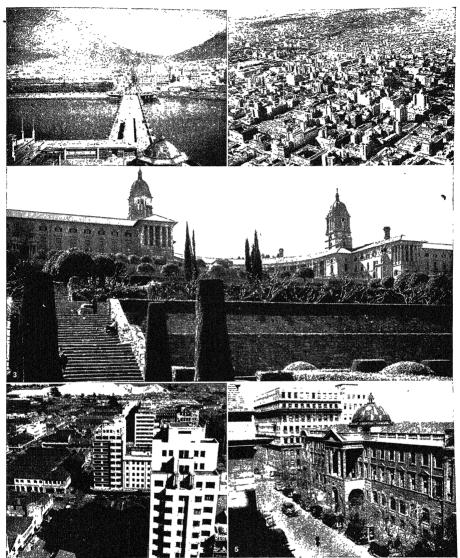

When they had got their bearings the 1820 settlers were dismayed to find that the legal system of the colony was alien to them, the judges were officials without any particular legal training and Lord Charles Somerset, the governor from 1814 to 1826, was an autocrat who made it impossible for them to publish a newspaper. Their agitation for British liberties and institutions evoked some response. The Charter of Justice of 1827 created a supreme court of qualified judges with security of tenure, abolished the heemraden and introduced English rules of procedure and evidence, including the jury system, while it left untouched the Roman-Dutch substance of the law. In 1834 an executive council of officials and a legislative council of officials and nominated nonofficials were established. By that time the freedom of the press had been won, English had become the official language of the courts, and British teachers had been imported to start village schools in which English was the medium of instruction,

During these years South Africa was attracting the attention of the British humanitarians or evangelicals who were striving to free the nonwhite races in the colonies from their legal disabilities. They were supplied with severe criticisms of South African conditions by John Philip. South African superintendent of the London Missionary society, which had established a number of mission stations up and down the country. Philip reached the conclusion that the Hottentot code of 1800, with its stringent pass regulations, was unjust; in 1826 he returned to England to appeal to the government and the British public, and in 1828 the house of commons passed a resolution for the emancipation of the Hottentots. Seeing the trend of affairs, Gen. R. Bourke, the acting governor, had already passed an ordinance, no. 50 of 1828, which abolished the pass system and gave "free persons of colour" complete liberty of movement Meanwhile, with their eyes focussed primarily on the British West Indies, the British government had been insisting on improvements in the treatment of slaves; and in 1833 the reformed parliament passed the emancipation act under which all slaves in the colonies became free after a period of apprenticeship, and £20,000,000 was voted as compensation to their owners. When their period of apprenticeship ended in 1838 the former slaves in the Cape colony stepped into the position of other "free persons of colour." Thereafter the emancipated slaves and Hottentots-the Cape coloured people-became a rural and urban working class in the Cape colony.

Meanwhile the frontier had flared up again. Unrest had developed among the border African tribes for various reasons, including the frequency of military raids on their villages made in reprisal for the theft of stock from white farmers. In 1834 Gen. Sir Benjamin D'Urban arrived as governor with instructions to devise a more equitable policy, but he did nothing about it before. at the end of that year, large bodies of Africans had invaded the colony and done serious damage. D'Urban then reasserted British military superiority and annexed the land up to the Great Kei river, from which most of the Africans were to be expelled (May 1835). But he found it impossible to enforce the expulsion, and the colonial secretary, Lord Glenelg, disapproved; consequently, in 1836 the territory was disannexed and an attempt was made to pacify the tribes by making treaties with their chiefs. By that time, however, the frontier was no longer a clear line of division between the races; white traders and missionaries were working among the tribes to the east of it, and Africans were working on white farms to the west.

Afrikaner Reaction and the Great Trek .-- For several generations the trekboeren had been left more or less to their own devices. Now, under an alien government actuated by liberal ideals which they did not comprehend, many of their institutions were being transformed, they were short of labour, they found it difficult to comply with the regulations and get the compensation money for their slaves, their property was being pilfered by wandering Hottentots, and they suffered further losses during the 1834 African invasion. Behind all these things they saw the hand of missionaries, who, they considered, misrepresented them in England. The reversal of D'Urban's frontier policy of May 1835 was the last straw that made many of them decide to throw off British dust and find a new home where they could, in the words of Piet Retief, their ablest leader, "preserve proper relations between master and servant." Later, Anna Steenkamp recorded that the British had placed their slaves "on an equal footing with Christians, contrary to the laws of God and the natural distinctions of race and religion, so that it was intolerable for any decent Christian to bow down beneath such a yoke; wherefore we withdrew in order thus to preserve our doctrines in purity." Imbued with this spirit the voortrekkers, about 12,000 Afrikaners, men, women and children, left the colony with their sheep, their cattle, their ox wagons and their coloured servants between 1835 and 1843.

In the previous two decades there had been widespread destruction and dislocation among the African tribes, caused by the Zulus under Chaka (Tshaka) and their offshoot, the Matabele, under Moselekatse. By the time of the Great Trek two areas seemed suitable for white settlement-Natal, south of the Tugela river. and the high veld, on either side of the Vaal. But appearances were deceptive, for these two areas were kept denuded by Zulu and Matabele impis or warriors. The first voortrekkers made for the high veld, where they were attacked by the Matabele, whom they routed in 1837. Most of them then decided to settle in Natal. Piet Retief went to the kraal of Dingaan, Chaka's successor, to negotiate for a cession of land; and there, in Feb. 1838, he and

70 Boers and 30 coloured servants were treacherously massacred, while another 300 Boers, mainly women and children, and 200 coloured servants, were killed in upper Natal. On Dec. 16, 1838, however, Andries Pretorius gained a decisive victory over the Zulus at Blood river Most of the voortrekkers then proceeded to stake out farms in Natal. Border troubles ensued, and when in 1840 a commando made a sortie to the south against the kraals of a chief named Ncapaai, his neighbour Faku, who had a treaty with the British, appealed for aid. Previously the British had been undecided what to do about the voortrekkers; the Cape of Good Hope Punishment act of 1836 had made them liable, as British subjects, to trial in British courts for crimes committed south of latitude 25° S., but little had been done to make it effective. Now, however, anxious lest the activities of Natal commandos would lead to disturbances on the Cape frontier, the governor, Sir George Napier, sent a small force to Natal which, after some fighting, became British territory in 1843. Most of the voortrekkers who had settled in Natal then inspanned their oxen again and trekked back to the high veld, north of the Vaal river, where they proved to be immune from further British attention for a generation.

Between the Orange and the Vaal, however, the British were drawn in for a while. There was a racial medley in that region: Griquas (Hottentot-European half-castes), who had been living on the northern side of the Orange river for several decades; Africans, survivors of the Matabele devastation of the high veld, who had been rallied by Moshesh near the Caledon river; and Afrikaners, both trekboeren, who had no particular grudge against the British, and voortrekkers, who had. The British had made a treaty with the West Griqua chief, Andries Waterboer, in 1834, and in 1843 they made treaties with the East Griqua chief, Adam Kok III, and with Moshesh, hoping to use them to keep the peace along the Orange river. Trouble followed when Kok, in accordance with his treaty, tried to hand an Afrikaner over to the Cape authorities for trial under the Punishment act. The Afrikaners took up arms and were dispersed by troops from the Cape at Zwartkoppies (1845). Two years later Gen. Sir Harry Smith became governor of the Cape colony and British high commissioner in South Africa. An optimist, he believed that the South African imbroglio would be pacified if the area of British authority was extended. Accordingly, after overcoming further African resistance on the eastern frontier of the Cape, he annexed the land up to the Great Kei river as the province of British Kaffraria (1847) and the land between the Orange and the Vaal as the Orange River sovereignty (1848). The colonial secretary, Earl Grey, accepted these annexations most grudgingly. Humanitarian influence was waning in Britain and the main concern of the colonial office was to cut down expenses. Therefore, when further fighting broke out on the eastern frontier and similar difficulties developed in the sovereignty with Moshesh, the British government decided to reduce its commitments in South Africa by recognizing the independence of the voortrekkers. This was done in two stages. In 1852 the commissioners W. Hogge and C. M. Owen granted the Transvaalers "the right to manage their own affairs without any interference on the part of the British government" in a convention signed at the Sand river; and in 1854 Sir George Clerk made similar arrangements with the Afrikaners of the Vaal-Orange area at Bloemfontein. South Africa was thus divided into two camps: Afrikaner republics and British colonies.

The Afrikaner Republics.—At the time of the Bloemfontein convention there were about 15,000 white persons engaged in pastoral farming in what then became the Orange Free State. They soon agreed on a rigid constitution, which vested legislative power in an elected volksraad, executive power in an elected president—the voters being the white male adults—and local administration in landdrosten and heemraden on the old Cape model. The East Griqua question was settled in 1860 when Adam Kok sold out his remaining land rights in the Free State and trekked with his people to found a new East Griqualand nearer the coast. The Basuto question was more difficult. The British had abandoned the sovereignty because they shirked the expense of controlling the brisk rivalry between the Afrikaners and the Basuto for the

Caledon river valley, which included some of the best arable land in southern Africa. When fighting broke out in 1858 the Basuto outmanoeuvred the Free Staters, who were glad to accept the mediation of high commissioner Sir George Grey (First Convention of Aliwal North). The Free Staters, conscious of their weakness, then tried to unite with the Transvaal, but were stopped by Grey, who threatened to withdraw the recognition of their independence and advised them to federate with the Cape colony; yet when they expressed a desire to do so, the British government refused. Further fighting started in 1864; this time the Free Staters were more successful and were able to dictate stringent terms, by which Moshesh lost most of his arable land (treaty of Thaba Bosigo, 1866). But the peace was not kept and Moshesh asked to be taken under British protection. This was done in 1868 and the next year the frontier line between the Free State and Basutoland was agreed upon (Second Convention of Aliwal North). The intervention of the British preserved for the Basuto people more land than had been left to them in 1866; but it gave serious offense to the Free Staters, depriving them of the fluits of their victory Thereafter the Free State, its frontiers pacified, and absolved from the responsibility of administering a large number of Africans, became what Tames Bryce once described as a model republic, under the wise leadership of J. H. Brand, president from 1864 to 1888. The Cape colony took over Basutsland in 1871, but later got into difficulties in trying to force the Basuto to forfeit their arms and was glad to hand it back to Great Britain in 1884.

Meanwhile the voortrekkers north of the Vaal river, numbering perhaps 22,000 at the time of the Sand river convention, preserved their old trekboer mode of life. It was not until 1858 that most of them overcame their factional disputes and united to form the South African republic under the presidency of M. W. Pretorius, son of the victor of Blood river. Their constitution, which created institutions similar to those in the Free State, frankly stated that "The people desire to permit no equality between coloured people and the white inhabitants, either in church or state." Otherwise it was an ambiguous document and from the first the volksraad ignored any restraint but that of force. In 1863 there was further factional fighting; and Boer expansion frequently led to disputes with African tribes, the weaker of which were broken up, the remnants becoming squatters and servants under white landowners.

The British Colonies After the Great Trek .-- Not more than a quarter of the Afrikaners had left the Cape colony. Those who remained gradually became accustomed to the more equal order and in the course of time a liberal tradition developed in the colony, in contrast with the illiberal tradition of the republics. When the colony received representative government in 1853, the only franchise qualifications were low economic ones, irrespective of race or colour; but most of the coloured people were unable to qualify and the vast majority of the electorate were white men. By that time the loss of population had been offset by further British immigration; and the decline in wine farming caused by the removal of British tariff preferences was remedied by an increase in the production of wool for export. In British Kaffraria the high commissioner, Sir George Grey, tried to achieve quick results from a policy of civilizing the Africans by encouraging trade, mission schools, medical services and public works, by bringing in white settlers and by using white magistrates to undermine the authority of the chiefs.

There was a reaction in 1857, when the Africans destroyed their own stock and crops in the superstitious belief that the white man would then vanish from the country. The result was catastrophic: thousands starved to death and emaciated survivors poured into the colony in search of work. In 1865 British Kaifaria was incorporated in the Cape colony, Soon afterward the British government urged the colony to assume full responsibility for its own affairs, and in 1872 a responsible government bill was carried and J. C. Molteno became first prime minister.

British immigrants had settled in Natal, so that its white population became predominantly British and crept up to 9,000 in 1856, when representative institutions were established, and to

50,000 in 1803, when responsible government was obtained. Mixed farming was practised inland and sugar was grown in the subtropical coastal belt. One result of the defeat of Dingaan was an influx of Africans from Zululand into Natal, many of them returning to the region from which they had formerly been evicted by Chaka. Thus the African population rose steeply from about 20,000 in 1840 to nearly 500,000 in 1803. They were handled by Theophilus Shepstone, the son of a missionary who had come to South Africa with the 1820 settlers. He placed most of the Africans in a number of reserves or locations, comprising about one-seventh of the total area of the colony. Their tribal laws and customs were maintained and they were able to preserve their tribal economy for another generation, when they began to suffer from land shortage. Africans subject to tribal law were not eligible for the franchise, but in 1864-65 laws were passed which enabled Africans to apply to be exempted from tribal law and, seven years later, for the franchise. However, the regulations were such that few became exempted and hardly any became

The colonists were critical of Shepstone's policy, mainly because it did not make the Africans work for them. The coastal sugar planters, in particular, were short of labour and it was to help them that Natal began to import Indian labourers in 1860. By £666, 6,000 had arrived, and as their five-year contracts expired most of them chose to stay in Natal, as they were entitled to do. In 1872 the Indian government prohibited further immigration because some of the Indians had complained of ill treatment; but the migration was resumed on a large scale, with a heavy government subsidy, in 1874, and by the end of the century the Indians outnumbered the whites.

## THROUGH WAR TO UNION (1870-1910)

Diamonds and Gold.-After 1870 the South African economy was rapidly transformed. Previously South Africa had been an economic backwater, with most of its inhabitants, whites and nonwhites, engaged in inefficient near-subsistence farming; and it had lacked the means to attract the capital and the skilled personnel to create the facilities of a modern country. In 1867 alluvial diamonds were found along the Orange and the Vaal rivers; in 1870 the dry diamond diggings began to be worked at Kimberley; and in 1886 the gold rush to the Witwatersrand began to eclipse all previous gold rushes. The effects were remarkable. The sum of South Africa's imports and exports rose from £49,000,000 in the decade 1861-70 to £128,000,000 in 1871-80, £179,000,000 in 1881-90, £357,000,000 in 1891-1900 and £700,000,000 in 1901-10. In the last of these decades gold (59%) and diamonds (19%) accounted for 78% of South Africa's exports; and by 1910 £121,-000,000 had been invested in the Witwatersrand gold-mining industry and dividends totalling £77,000,000 had been paid by it. Immigration raised the white population from about 328,000 in 1875 to 1,117,000 in 1904. Railway construction was even more striking: in 1870 there were only 69 mi. of railway track in all South Africa; by 1886 there were 1,800 mi. and the line from Cape Town had reached Kimberley; by 1895 there were 3,600 mi. and Johannesburg was connected with five ports—Cape Town, Port Elizabeth, East London, Durban and Lourenço Marques. Thus South Africa at last entered the world economy and acquired a special place in it as the source of about a third of the world's annual supply of gold and more than half its diamonds.

The control of these great industries became concentrated in a few hands. The digger phase on the diamond fields was short-lived; companies forced out individuals and then the companies amalgamated until in 1890 De Beers Consolidated Mines controlled the entire South African diamond industry. The digger phase on the gold fields was even shorter, but there the process of concentration never reached quite the same finality; companies became organized into groups or corporations, and the groups became associated in the chamber of mines for certain purposes only, notably for the recruitment of African labour. Thus great financial power came to be exercised by a few men, above all by Cecil Rhodes (1853-1902), who went to South Africa for his health in 1870 and became the most successful of all the mining

financiers, controlling both De Beers and the Consolidated Gold Fields, one of the strongest gold corporations

The skilled work in the mining industries was done by whites, mainly immigrants at first, who drew high wages. The unskilled work was done by low-pand Africans who came to the mines from all over southern Africa, especially from Portuguese East Africa, to work for limited periods during which they lived in closed compounds, separated from the ordinary life of the community In 1898, for example, the Witwatersrand gold-mining industry employed 9,476 whites at an average monthly wage of £2 95. Previously many Africans at an average monthly wage of £2 95. Previously many Africans had been employed as farm labourers in return for squatting rights or low wages. Now the agrarian pattern of race relationships was being adapted to the mining industries, which, having a voracious appetite for labour, were giving a distinct impetus to the long-drawn-out process of the disintegration of tribalism.

Annexation of the Diamond Fields .- The discovery of diamonds led to a serious controversy. The Transvaal claimed part of the diamondiferous area and the Orange Free State claimed the rest of it, while David Arnot, a white attorney, claimed it all on behalf of his client Nicholas Waterboer, the chief of the West Griquas. Arnot managed to persuade the British colonial office that the Griquas had the best case; therefore when a new high commissioner, Sir Henry Barkly, reached South Africa in Jan. 1871 he had instructions to take a strong line. Barkly persuaded M. W. Pretorius, the Transvaal president, to submit his case to arbitration by R. W. Keate, the governor of Natal. When Keate discovered that Pretorius had unwittingly placed great reliance on a forged document, he decided against him. Although this award did not directly affect the Free State claims, which were the strongest, Barkly, failing to understand their merits, annexed to the crown the entire area claimed for Waterboer in the same month (Oct. 1871). Five years later a land court decision exposed the fallacies in Waterboer's claim to sovereignty over the diamond fields; whereupon J. H. Brand, the Free State president. went to London and exacted £90,000 compensation from the imperial government. In 1880 Griqualand West was incorporated in the Cape colony.

Annexation and Retrocession of the Transvaal.—When in 1874 Benjamin Disraeli formed a ministry, Lord Carnarvon, his colonial secretary, hoped that the South African states and colonies might unite in a self-governing federation under the British crown. The following year he summoned a conference to discuss the project in London, but it was a failure: the Free State, smarting under the recent annexations, would have nothing to do with the project; nor would the Cape, whose ministers' dignity had been ruffled by the conduct of the historian J. A. Froude, who had toured the colony on behalf of Carnarvon urging federation. Federation from the south having failed, Carnarvon turned his attention to the north and found that the South African republic was ripe for plucking.

That republic, unlike the Free State, had never acquired stability. Pretorius was bundled out of the presidency after the annexation of Griqualand West, and the Transvaalers chose as his successor the Rev. T. F. Burgers, a Cape colonial predikant. But in Burgers they had more than they had reckoned for; he was critical of Transvaal backwardness and proposed to remedy it by social, educational and religious reforms. He also borrowed money, intending to build a railway to Delagoa bay to free the Transvaal from its dependence upon British trade routes; but not a single track of the railway was laid, whereas the loan strained the meagre resources of the republic and alarmed the Cape and Natal merchants whose interests it threatened. When in 1876 Burgers personally waged an unsuccessful campaign against the Bapedi tribe in the northern Transvaal, he was totally discredited. The Afrikaners, including Paul Kruger, were plotting against him, and the traders were conniving with the Cape and Natal mer-chants to bring in the British. Carnarvon heard their cries and commissioned the newly knighted Theophilus Shepstone to annex the Transvaal. Entering the republic in Jan. 1877 with 25 police and a staff of seven Shepstone annexed it in April in a proclamation which promised "the fullest legislative privileges compatible" with the circumstances of the country and the intelligence of the people"

But British rule in the Transvaal was neither efficient nor tactful and the elected legislature did not materialize. Then the Zulu war revealed the weakness of British arms: the Zulus, their martial spirit revived by Cetywayo, routed a large British force at Isandhlwana in 1879 before they were vanquished in the following year. By that time the Transvaalers, who had passively acquiesced in the annexation, were moving toward open rebellion under the leadership of Paul Kruger, M. W. Pretorius and P. J. Joubert, and in 1881 they, too, wiped out a British force at Ma-W E Gladstone's ministry, which assumed office in 1880 but failed to reform the Transvaal administration in time to avert the rebellion, now gave the Transvaalers a qualified independence (Pretoria convention, 1881). Three years later they allowed the republic full internal autonomy, while maintaining British control over its relations with foreign states, other than the Free State (London convention, 1884). Carnarvon's project had completely miscarried, and his permissive act for the unification of South Africa (1877) was stillborn.

The Rhodes-Hofmeyr Alliance.-In the Cape, which remained the most civilized of the South African states, the advent of responsible government and the series of British annexations prompted a group of Afrikaners to form a political organization, the Afrikaner Bond, in 1879. At first the Bond's program was crudely sectional, but three years later J. H. Hofmeyr (1845-1909) gained control and turned it in the direction of Anglo-Afrikaner co-operation, with a British South African federation, which should include the republics, as the ultimate goal. Meanwhile Cecil Rhodes had entered the Cape parliament and, as his vision of British expansion in Africa was reconcilable with Hofmeyr's, he was able to form a ministry with Bond support in 1890. Moreover, although the Cape had mishandled Basutoland, a more promising native policy was developing in the Transkeian territories up to the Natal border, which were gradually annexed between 1872 and 1894. Nearly all the land was left in African possession. African tribal law was recognized, and a corps of able and sympathetic administrators was created. But these annexations raised serious political questions because they caused the African population of the colony to increase threefold and far outstrip the white population. The Cape parliament accordingly granted the territories a modicum of political representation, while making it clear that occupation of land on tribal or communal tenure did not constitute a qualification for the franchise (1887), raised the economic qualifications slightly and added a simple educational test (1892) and encouraged the Africans to adopt individual land tenure and to elect local administrative councils (1894). The native policy of the Cape was thus based on the principle that the Africans should gradually change from the tribal to the western mode of life, and that those who had made the change should have the same civil and political rights as white men. By 1895, therefore, the Rhodes-Hofmeyr alliance was bidding fair to heal Anglo-Afrikaner quarrels and to maintain a promising basis for relations between the whites and the nonwhites in the Cape colony.

British Clash With the Transvaal .- Meanwhile the scramble for Africa was taking place, and in 1884 Germany took over South-West Africa and Transvaalers began to encroach westward toward it, setting up the republics of Stellaland and Goshen. This expansion, which seemed likely to cut off the British from access to central Africa via the Cape, was checked, largely on the insistence of Cecil Rhodes, in 1885, when Great Britain after a display of force proclaimed a protectorate over northern Bechuanaland and annexed southern Bechuanaland as a crown colony. Transvaal efforts to keep their north clear of the British were also foiled by Rhodes, who secured a prospecting concession from the Matabele chief Lobengula in 1888, obtained a royal charter incorporating the British South Africa company to exploit the concession in 1889, and dispatched a pioneer expedition to occupy what became known as Rhodesia in 1890 (see RHODESIA: History). Finally, the Transvaalers tried to push eastward to get

a port on the Indian ocean, but, although they incorporated fresh territory including Swaziland, they did not reach the coast, as Britain annexed Zululand in 1887, and Tongaland, the last gap, in 1895. The Afrikaner republics were thus encircled by the colonies of Great Britain and its oldest ally, Portugal—hemmed in a kraal, as Paul Kruger complained Southern Bechuanaland was taken in by the Cape colony in 1895; Zululand and Tongaland by Natal in 1897; but northern Bechuanaland remained a British protectorate like Basutoland.

In 1883 Paul Kruger (1825-1904) was elected president of the Transvaal. His character had been moulded in the hard school of the Great Trek and of commando fighting against Afrikaner factions and African tribes; and recently he had led the opposition to President Burgers and the British. His policy was to regain complete independence for the republic and to preserve Afrikaner control of it. In 1885 he was constrained to suggest a customs union with the Cape, whose government rejected the offer. Soon afterward his financial difficulties were solved by the gold discoveries, and he proceeded to use the mining industry as a milch cow, imposing heavy taxation and granting monopolies of essential materials, such as dynamite. Nevertheless, the growth of such an industry in the heart of his republic posed serious problems. The Afrikaners became outnumbered by the newcomers who poured in from all parts of the world, most of them Pritish subjects. To give these Uitlanders an effective vote seemed like suicide; to withhold such a vote was bound to cause trouble with the British. Kruger never hesitated. he progressively raised the franchise qualifications until by 1894 no Uitlander could vote in presidential elections, and only those who were 40 years old and had lived 14 years in the Transvaal, during 12 of which they had been subject to an oath of allegiance, could vote in volksraad elections. In short, on the one hand the government was corrupt and fleeced the Uitlanders and denied them political rights; on the other hand the Uitlanders continued to swarm into the republic where many of them prospered exceedingly. Such a situation required patience. Although Kruger was re-elected for a third term in 1893, his majority over the more moderate Jouhert was small and a change seemed likely in 1898.

But Rhodes was not patient. Finding that Kruger stood between him and a British South African federation, he planned to overthrow him. Kruger nearly played into Rhodes's hands in 1895 when, contrary to the London convention, he tried to injure Cape trade with the Transvaal and the Cape railways that were competing with the Delagoa bay line by making the rates over the Transvaal sector of the Cape line prohibitive and by closing the Vaal drifts to prevent the carriage of goods by wagon. But he gave way when the colonial secretary, Joseph Chamberlain, agreed to support the Cape ministry's protests, by force if necessary.

The Jameson Raid.—Rhodes then pushed ahead with his conspiracy: the Uitlanders were to rise, an armed force under L. S. Jameson was to come to their assistance, and the high commissioner was to hurry to Pretoria to "restore order." It is probable that Chamberlain knew of Rhodes's plans when he provided suitable jumping-off place for Jameson's force by ceding to the British South Africa company a strip of land along the Transvaal border of the Bechuanaland protectorate, but that he later withdrew his support when he learned that the Uitlander rising would not take place to give the invasion an air of respectability. Therefore, when Jameson, contrary to Rhodes's last-minute instructions rode into the Transvaal from Pitsani near Mafeking on Dec. 29, 1895, he was disowned by the colonial secretary and the high commissioner. Four days later he surrendered to Transvaal commandos at Doornkop.

The Outbreak of the South African War.—The raid fiasco cleared the decks for the South African War. Rhodes had to resign the premiership of the Cape colony, where, in 1898, W. P. Schreiner became head of a ministry which relied upon the support of the Bondsmen, who had been made deeply suspicious of British designs. In the Orange Free State, which had opposed, the Transvaal over the drifts crisis, M. T. Steyn was elected president and formed a military alliance with the Transvaal. While Steyn

and the Bond were not uncritical of the Kruger regime, Kruger's Anglophobia seemed to have been vindicated in the Transvaal, where he won the 1898 presidential election by a large majority. In England, on the other hand, a parliamentary committee failed to probe Chamberlain's dealings with the raiders, the kaiser's telegram congratulating Kruger turned Jameson and Rhodes into popular heroes, and the press paid much attention to *Uitlander* grievances.

As the tension mounted, Chamberlain, taking the high ground of British paramountcy in South Africa, claimed to be competent not merely to control the foreign relations of the Transvaal (a right expressly granted by the London convention) but also to intervene on behalf of the Uitlanders (which was not). Once the principle of intervention was asserted, there were grounds enough for exercising it. The tendency of the volksraad to give sweeping powers to the president was exemplified in the judges' crisis: in 1807 Chief Justice J. G. Kotzé delivered a judgment which meant that the greater part of the laws of the Transvaal had been enacted unconstitutionally and were null and void, whereupon the volksraad deprived the courts of the testing power and gave Kruger the power to dismiss any judge who disagreed; and the next year Kruger dismissed Kotzé. In 1808 an Anglo-German agreement removed the likelihood of German intervention in the event of a South African war, and Chamberlain and the high commissioner, Sir Alfred Milner, proceeded to apply the screw. The central issue was the Transvaal franchise. In June 1899, in conference at Bloemfontein, Milner proposed a simple five years' franchise, Kruger refused and the negotiations collapsed. The last chance of peace was lost in August when J. C. Smuts (1870-1950), Kruger's young state attorney, offered a five years' franchise and Chamberlain rejected the conditions which were attached to the offer. Milner had long since made up his mind that war was "inevitable," and in September Chamberlain arranged for 10,000 British troops to be sent to augment the meagre British forces in South Africa. The republicans, who had been arming furiously for several years, replied by issuing an ultimatum which expired on Oct. 12, 1899. For events of the war, see South African War.

Reconstruction and Union.-After the treaty of Vereeniging of May 31, 1902, Milner, high commissioner and governor of the crown colonies-the Transvaal and the Orange River colonyconcentrated on their material reconstruction from the ravages of war. The gold mines resumed large-scale operations, and the Afrikaners were returned to their land from the prison and concentration camps and supplied with food, stock, seed and implements, no less than £10,000,000 being spent by Great Britain on their rehabilitation. Milner also prepared the ground for political union by bringing all the colonies into a South African customs union and by amalgamating the railways of the Transvaal and the Orange River colony. All this work was well done by Milner and his band of exceptionally able young men, who were dubbed the "kindergarten." But the opportunity was not used to emancipate the nonwhite inhabitants of the crown colonies from their legal disabilities, which remained much as they had been during the republican regime. Nor did Milner gain the confidence of the Afrikaners: they disliked him as "the man who made the war," who openly supported the anti-Bond agitation for the suspension of the Cape constitution in 1902, who imposed an English educational system on the crown colonies and who was responsible for bringing Chinese labourers to the Witwatersrand gold mines in 1904. For the importation of Chinese labourers there were, indeed, strong economic reasons, because the supply of African mine labour had temporarily fallen off; but the decision played a large part in the rout of the British Unionist party at the polls in 1005-06.

The change of government in Britain was followed by a radical change in the distribution of power in South Africa. Sir Henry Campbell-Bannerman's Liberal ministry, anxious to make amends to the Afrikaners for a war which had been brought about by their predecessors, decided to give the new colonies responsible government—on an exclusively white franchise, as had been promised at Vereniging. Consequently in March 1907 Louis Botha (1862–1919), former commandant general of the forces of the

South African republic, became premier of the Transvaal, with J. C. Smuts as his right-hand man, and in Dec. 1907 A. Fischer became premier of the Orange River colony. The swing of the pendulum was completed in Feb. 1908, when J. X. Merriman's South African party, consisting largely of the Afrikaner Bond, ousted Jameson's Progressives from office in the Cape colony

The high commissioner, Lord Selborne, who succeeded Milner in 1905, argued the case for union in a memorandum published in July 1907, and, once in power, the three Afrikaner parties took it up enthusiastically, with the support of their oppositions. White public opinion in South Africa moved steadtly in favour of union, partly out of an idealistic feeling that it was best to bury the hatchet and make a new start on a basis of white equality, and partly because the African rebellion in Natal in 1906 led many to think union essential for white security; some, moreover, saw in union the best way of guarding against any further British interference in South African affairs. There were also compelling economic reasons for union: the four colonies were interdependent and yet, without political union, their material interests were odivergent that the customs union seemed bound to collapse.

Accordingly a national convention, comprising 30 members appointed by the four colonial parliaments and 3 nonvoting members from Rhodesia, met in 1908 and 1909 under the chairmanship of Sir Henry de Villiers, chief justice of the Cape. A constitution was drafted and unanimously approved by the convenuon; it was then carried with few dissentients in the parliaments of the Cape colony, the Transvaal and the Orange River colony, and by a large majority of the electorate in a referendum in Natal. Finally, in Aug. 1909, it was enacted by the British parliament, substantially as it had been submitted to the British government by delegates from South Africa. The South Africa act came into force on May 31, 1910, and the four colonies became the provinces of the Union of South Africa.

The constitution is described elsewhere in this article (see Constitution, below), but a few points require comment here. The convention, except for the Natal members, wanted a close union and complete flexibility, and they were largely successful; the principal feature of the South African constitution was the grant of power to parliament to legislate on practically every subject by simple majorities in each house. Nevertheless, on two subjects they did not grant parliament such extensive powers. First, the Afrikaner members wanted special protection for the section which gave Dutch (to which Afrikaans was added in 1925) equal status with English as an official language of the Union. Second, the convention could not agree on a uniform franchise for the Union, the Cape delegates favouring a colour-blind franchise and the others a rigid colour bar. Eventually a compromise was reached whereby the franchise qualifications were to remain as they were in each province and the established franchise rights of the Cape nonwhites were specially protected. Accordingly, the sections on language equality and the Cape nonwhite franchise were to be amended only with the approval of two-thirds of the members of both houses of parliament, assembled in joint session. The act also made it possible for Rhodesia to join the union on terms to be approved by the privy council and for the protectorates of Basutoland, Bechuanaland and Swaziland to join on terms laid down in a schedule, but only with the consent of the imperial government, which had special commitments to their African inhabitants.

# THE UNION OF SOUTH AFRICA

The Race Issue.—The dominating factor in the history of the Union of South Africa has been the exceptionally complex character of the population. In 1910 there were nearly 6,000,000 inhabitants, of whom, 21½% were whites, 67% Africans, 9% coloured people and 2½% Asiatics. After that time, while the total population more than doubled, the racial proportions remained about the same. The whites included an Afrikaner majority, who were mainly rural, and a British minority, who were mainly urban, Between them they owned most of the land and the capital, did most of the skilled work and possessed 93%, of the votes. The Africans were still predominantly tribal rather than western in

culture, but, as a result of their conquest and of white missionary activity and economic enterprise, there was already a distinct frend toward the disintegration of tribalism. Although most Africans still had homes of sorts in the reserves, those were scattered lands which amounted to only one-fourteenth of the area of the country and by no means provided them all with a livelihood; consequently, many Africans went out to earn wages on white farms and in the towns. Moreover about 1,000,000 Africans had long been established as squatters on white farms and a few were already completely urbanized. The Africans were subject to pass laws which restricted their movements outside the reserves, to Masters and Servants laws which made breach of contract a criminal offense in many types of employment, to special taxation and to other special laws. These laws varied from province to province, and in the Cape there were about 7,000 African voters who were exempted from some of them. coloured people were western in culture. Most of them lived in the Cape province, where their status was that of the whites, and about 14,000 were voters, whereas in the other provinces they were subject to discrimination. The Asiatics were mainly the product of the indentured Indian immigration scheme to Natal, where they outnumbered the whites and were subject to special laws, including a £3 tax. They were excluded from the Orange Free State, but about 11,000 had settled in the Transvaal, where, too, they came under special laws.

The policies of South African governments differed on many important issues; but all, being responsible to a predominantly white electorate, stood more or less explicitly for "the maintenance of white supremacy," a task which became increasingly difficult as a result of the rapid tempo of economic development in the Union and the change in the balance of power and the climate of public opinion elsewhere.

The Botha-Smuts Regime, 1910-24.—In 1910 the Afrikaner parties in the colonies merged to form the South African party, which, under Louis Botha and J. C. Smuts, governed the country until 1924. Botha and Smuts had been zealous fighters for republican independence so long as there was a chance of success, but they were realistic enough to accept the inevitable at Vereeniging and imaginative enough to see great prospects for South Africa when the hot mood of British imperialism had spent itself. By 1910 they conceived of the coalescing of the British and Afrikaner elements into a white South African nation which would freely cooperate with the British Commonwealth in peace and in war. The ideal went too far, however, for the more conservative Afrikaners, who were concerned with preserving their group identity, and not far enough for the more self-conscious nonwhites, for whom it implied a permanently inferior status.

The government wished to keep most of the Africans in the reserves to prevent the whites from being swamped, and to use African manpower as the unskilled base of all forms of economic enterprise-objectives which involved certain contradictions. As the Africans became more accustomed to a money economy, some of them were liable, unless checked by law, to compete successfully with the less efficient whites. This was already happening in the gold-mining industry, and laws were passed in 1911 to preserve the racial hierarchy in that industry. Such competition was also happening in some rural areas, where Africans were pooling their resources to buy more land; a Natives Land act was passed in 1913 to limit the areas within which such purchases could be made. Neither of these acts was wholly effective. In 1916 a commission reported that if the policy of territorial segregation was to be carried out the reserves should be substantially increased in size, but little was done about it because the whites were not prepared to make the necessary sacrifices.

The Asiatic question had reached a more crucial phase. Already before union M. K. Gandhi (1869–1948) had organized passive resistance against the Transvaal government, and after union he resumed the struggle against the £3 tax in Natal. As a result the Indian government stopped the importation of indentured Indian labourers in 1911 and the £3 tax was removed in 1914. By that time the pattern of later disputes had developed: the Union government regarded the Indians as temporary visitors and tried to

persuade them to return to India; and most of the Indians regarded themselves as permanent residents and demanded full rights of citizenship.

The conservative Afrikaners had found their leader in J B M. Hertzog (1866-1942). Although he had joined the Botha cabinet in 1910, Hertzog regarded his colleagues' policy as liable to cause the Anglicization of the Afrikaner people, and he publicly advocated a different, "twin-stream" policy, which led to his exclusion from a reconstituted cabinet in 1912 and to the foundation of the Nationalist party. When in 1014 the government unhesitatingly took the part of Great Britain in World War I and parliament voted funds for the conquest of German South-West Africa, a number of former republican generals, some of whom held appointments in the South African defense force, came out in rebellion to avenge Vereeniging. After mastering the rebellion, Botha took command of the South-West African expedition and forced the Germans to capitulate on July 9, 1915. South African volunteer contingents also fought in East Africa and on the western front in Europe, where they distinguished themselves at Delville Wood (July 1916), and many individuals joined British units. Smuts, after serving as commander in chief in East Africa, did notable work in the British war cabinet. In July 1919 he and Botha, on behalf of South Africa, signed the treaty of Versailles and the covenant of the League of Nations, under which South-West Africa became a Union mandate. Back in South Africa Botha died before August was out, and Smuts, succeeding to the premiership, faced the discontents caused by thwarted Afrikaner nationalism, a steep rise in the cost of living and industrial

As early as 1907 Smuts had intervened on the side of the employers in a strike of white workers on the Witwatersrand, and in 1914 he had ended another strike by declaring martial law and illegally deporting nine strike leaders. After the war there was a serious crisis. The Chamber of Mines, faced with rising costs and a fall in the price of gold, decided to organize the industry more rationally by using Africans for semiskilled work. There was a violent reaction by white labour, which Smuts suppressed at a cost of 230 lives, with the result that, although the threat to relax the colour bar was not carried out, the Labour party, representing the aggrieved white workers, made an electoral pact with the Nationalists. In the hope of redressing the political balance, Smuts wooed the Southern Rhodesian electorate to accept incorporation in the Union, but when a referendum was held on the issue in 1922 they preferred to remain separate. Two years later the South African party was heavily defeated at the polls and Hertzog became premier of a Nationalist-Labour coalition.

and herizog's Nationalist Policy, 1924—33.—Hertzog's Nationalist Policy, 1924—33.—Hertzog's Nationalist Policy, 1924—33.—Hertzog's main objectives were to complete the emancipation of South Africa from imperial control and to provide greater protection for the whites from the Africans and for the Afrikaners from the British. He played a notable part in the events leading to the Balfour Declaration (1926) and the Statute of Westminster (1931), which gave statutory definition to the established convention that the British government could not exert authority over a dominion. South Africa's sovereign status was also asserted by the adoption, after a long and bitter controversy, of a distinctive national flag (1927), by the appointment of ambassadors to Rome, Washington and The Hague (1929), and by the separation of the office of governor general, the head of the South African government, from that of high commissioner, the representative of the British government in South Africa (1931).

Economic nationalism was fostered by the foundation of a state-controlled iron and steel works at Pretoria, by increased protection for agriculture and industry, by a reduction in imperial preferences and by a commercial treaty with Germany. White supremacy was bolstered by the provision of sheltered employment for "poor whites" in state enterprises, by a Mines and Works Amendment act (1926), which was more effective than its predecessor in shutting Africans out from skilled mining trades, by a Native Administration act (1927) and a Riotous Assemblies act (1930), which gave the executive wide powers over individuals, and by franchise acts (1930–31), which extended the vote to all

white men and women, while they left the Cape nonwhite vote as before, restricted to men who possessed property and educational qualifications. Hertzog's legislative program was still incomplete when the 1930 world depression undermined the prosperity of the country and the popularity of the government, which continued to cling to the gold standard after Great Britain had abandoned it in 1931. After the government, yielding to pressure from some of its own supporters, left the gold standard in Dec. 1932, there was a fairly rapid economic recovery, but political confusion continued until, in 1933, Hertzog and Smuts formed a coalition government which secured overwhelming support from the electorate.

The Hertzog-Smuts Regime, 1933-39 .- The coalition was based on a great deal of common ground between Hertzog and Smuts. Hertzog no longer feared political co-operation with Smuts's British supporters, believing that the Afrikaners had been raised to the point where they were immune from the danger of Anglicization, and Smuts was reconciled to most of Hertzog's achievements and was prepared to collaborate with him in rounding them off. Consequently, in 1934 the two major parties fused to form the United party; but Hertzog failed to carry with him a small group of Afrikaner irreconcilables, led by D F. Malan, who formed the Purified Nationalist party, while C. F. Stallard at the other extreme dissociated himself from Smuts and formed the Dominion party. By then the constitutional settlement had been completed by the Status act and the Seals act (1934) which secured, so far as words could do, that South Africa was master in its own house. The government then proceeded to complete Hertzog's segregation legislation. A Representation of Natives act (1936) removed the Cape province African voters from the common roll and gave them the right to elect three white members to represent them in the lower house, gave the Africans throughout the Union the right to elect four white senators, and created a Natives' Representative council with advisory powers. A Native Trust and Land act (1936) provided for a considerable increase in the size of the reserves. A Native Laws Amendment act (1937) authorized the executive to prevent more Africans from entering the towns and to compel municipalities to segregate African from white residents. It was Hertzog's hope that the enlarged reserves would become capable of maintaining almost all the African people, so that those who worked for whites could be regarded as temporary visitors from the reserves. But it is notable that he saw the need for consultation with an African council, and that he did not try to discriminate against the coloured people. Moreover, his government expanded the social services not only for the whites but also for the nonwhites; there was, for example, a considerable increase in government grants for education. Nevertheless, Africans, Indians and coloured people were becoming disturbed by the great contrast between their living standards and those of the whites and by an accumulation of laws which caused 500,000 Africans to be convicted of statutory and municipal offenses in a year and many more to come into unpleasant contact with a police force recruited from among the poorer Afrikaners, who were imbued with the strongest race prejudices. As tension began to mount the Nationalists claimed that "white South Africa" would not be safe unless the restrictions on Africans were increased and the coloured people were also segregated from the whites. Though Hertzog strongly disagreed, the Nationalists were able to profit from the celebrations held to mark the centenary of the Great Trek in 1938, when they appealed to all Afrikaners to remain true to the principles of the voortrekkers and of Paul Kruger, placing special emphasis on their race attitudes.

World War II.—The outbreak of World War II caused a crisis in South Africa. Although Hertzog and Smuts had co-operated successfully on many issues, they differed widely on foreign affairs. Hertzog took an indulgent view of Adolf Hitler's, reich, believed that its expansion was no concern of South Africa, and moved in the house of assembly, on Sept. 4, 1939, that South Africa should remain neutral. Smuts, keenly aware of the wider implications of Naziism, maintained that it was the interest and the duty of South Africa to support Great Britain, and he won

the crucial division by 80 votes to 67. On Sept. 5 Smuts formed a ministry with the support of the Labour party, the Dominion party and the majority of the United party, and war was declared on Germany.

The Smuts government concentrated its energies on the war. About 200,000 white men (most of them Afrikaners) and 125,000 nonwhites (mainly Africans and coloured men) joined the forces, and about half of them served with distinction in the Ethiopian, Mediterranean and Madagascan theatres. The nonwhites were not allowed to bear arms but were distributed among the combatant units, for whom they performed vital work as stretcherbearers, labourers, etc. In South Africa industry was efficiently switched to the production of munitions and clothing for military purposes. Smuts himself remained in close contact with Winston Churchill and watched carefully the strategy of the war, often leaving his able lieutenant, J. H. Hofmeyr, Jr. (1894-1948), to carry a lion's share of the burden of administration. South Africa's achievements were impressive, considering the strength of the opposition to the war. Fortunately for the government, the opposition splintered into fragments during the most critical period: J. F. van Rensburg's Ossewabrandwag and Oswald Pirow's New Order, accepting the racial doctrines of the Nazis and their contempt for parliamentary government, patently hoped to profit from a Nazi victory; the Malanites expounded the ideal of an Afrikaner republic in which, as in Kruger's republic, the British would not necessarily have political rights; while the Hertzogites stood firm by their principle of equality between the whites. In the first flush of his disappointment, indeed, Hertzog led his defeated minority from the United party to join hands with Malan and form the Reunited Nationalist party, but the reunion was not a happy one and before the end of 1940 Hertzog had been driven out for his tenderness toward the British. His colleague, N. C. Havenga, subsequently founded the Afrikaner party to maintain his ideals. The general election of 1943 was a victory for Smuts in that his prowar coalition secured a majority of 67 seats in a lower house of 153; but it was also in a sense a victory for Malan's Nationalists, who won all the 43 opposition seats. Thereafter, as the prospect of a Nazi victory faded, the Nationalists consolidated their position as the political instrument of selfconscious Afrikanerdom, absorbing elements from the Ossewabrandwag, the New Order and the Afrikaner party, and drawing support from a variety of cultural and economic organizations, including the Broederbond, a secret group of Afrikaner elite.

As the war drew to a close Smuts drafted the preamble to the United Nations charter signed at San Francisco, Calif., in 1945 and returned to mould postwar South Africa along the lines of a generous demobilization scheme, an expansion in the social services for all races, a planned development of agricultural, mineral and industrial resources, and large-scale white immigration.

The Industrial Revolution in South Africa.-Subsequent events can be understood only in relation to the fact that South Africa was experiencing an industrial revolution as intense as the British industrial revolution of the early 19th century, with the added complication of racial differences between the unskilled workers on the one hand and the skilled workers, the capitalists and the majority of the electorate on the other. The way had already been paved by the rise of the mining industries and by the foundation of many manufacturing industries during World War I and the 1930s; the rate of expansion increased during and after World War II. In the 15 years between 1936 and 1951 the total population increased by 32%. In the 13 years between 1938 and 1951 the output of coal, pig iron, iron ore, copper, electricity and many other commodities doubled. In the same period the revenue and the value of imports and exports quadrupled, while the net national income trebled. Even when a factor of about 10/18 is applied for the change in the value of money, these increases are exceptional.

The gold-mining industry continued to play a central role in the Union's economy, and fears that the supply would soon become exhausted were removed by the opening up of new mines in the Orange Free State, where production began in 1951. Nevertheless, gold production declined after 1941, because a fall in the

value of gold made it unprofitable to mine low-grade ores. Moreover, the expansion of the manufacturing industries diminished the relative importance of the gold industry, which produced only 10% of the national income and 20% of the exports in 1951. The mining industries continued to be organized on racial lines and the manufacturing industries adopted a similar basis; therefore skilled work remained virtually a white monopoly, most of the unskilled work being performed by nonwhites. An unusually wide gap continued to exist between the wage rates of the two

As a result of this expansion nearly three-quarters of the white population were townsmen in the early 1950s, the "poor whites' were absorbed by industry, and the earlier economic distinctions between the Afrikaner and the British inhabitants became blurred. Industry also attracted a vast number of nonwhites: more than 2,000,000 Africans-about a quarter of the total African population-lived in the towns. Into some of these towns the influx was so rapid that housing and other amenities were not adequate. But in spite of low wages and squalid living conditions, the urban Africans earned incomparably higher incomes than the rural Afri-

Malan's Nationalist Party Policy, 1948-53.—As the 1948 election approached, disturbing facts were becoming known in South Africa. For example, although the reserves had been enlarged under the 1936 act, the 1946 census revealed that only 40% of the African population lived there, and in 1948 a commission revealed the extent to which Africans were becoming permanent inhabitants of the towns. These facts did not square with the argument that the Africans had adequate homes in the reserves and could therefore be treated as inferiors elsewhere. Moreover, the growing restlessness of the urban Africans raised the question whether "white supremacy," which had developed in the primitive pastoral economy of the 18th century, could be maintained in the industrial economy of mid-20th century

The Smuts government tried to deal with practical grievances in a conciliatory spirit, while Hofmeyr went further than his colleagues on occasion, feeling toward a policy that would be acceptable to all races. But the Asiatics were protesting vigorously against legislation which prevented them from buying or occupying fresh premises in Durban, and the Indian government attacked South Africa at the United Nations general assembly. Consequently when in 1946 Smuts tried to persuade the U.N. general assembly to allow the Union to incorporate South-West Africa, he met with a rebuff, and the assembly passed the first of a series of resolutions condemning South Africa's racial policies.

The Nationalist leaders, steeped in the voortrekker tradition, expressed horror at the "liberalism" of the United party, declared it would cause the "suicide" of white South Africa, and propounded a theory of apartheid, according to which the races should be separated and each allowed to "develop along its own lines in its own area." Their propaganda, skilfully presented, served its purpose: in May 1948 Malan, with the assistance of N. C. Havenga's small Afrikaner party, was able to form a government which had a majority of five in the lower house.

A spate of legislation followed. Mixed marriages were made illegal; every person was to be classified by race in a population register; South Africa was to be gradually divided into an infinite number of racial zones; African tribalism was to be strengthened; and the Natives' Representative council was abolished. cretionary powers of the executive, already considerable, were increased by the sweeping Suppression of Communism and other acts. A Citizenship act extended the period of residence of British immigrants before they could apply for citizenship and the franchise, and a South-West African Affairs Amendment act gave the whites of that territory six seats in the lower house, which they promptly filled with Nationalists. But a further act to remove the 50,000 coloured voters from the common roll in the Cape province and give them, like the Africans, the right to elect three whites to represent them in the lower house was declared invalid by the supreme court, as being in conflict with the entrenched sections of the South Africa act, since it had not been passed by a two-thirds majority of the members of both houses in joint session; and although under a further act the Nationalist members of parliament, sitting as a "high court," reversed that decision, the supreme court subsequently held that the High Court of Parliament act was also invalid, on the same grounds.

While most of the white people in South Africa supported the objective of much of this legislation, the maintenance of "white supremacy," many disapproved of Nationalist methods and, in particular, of the attempt to override the entrenched sections of the constitution. The Torch Commando-a picturesque but misleading name for a thoroughly constitutional organization-was founded to invigorate the opposition to undemocratic methods of government; and among the British in Natal there was talk of secession from the Union. The United party, led by J. G. N. Strauss after the death of Smuts in 1950, was cautious and divided on the fundamental colour issue. But there was a growing number of white South Africans, Afrikaners as well as British, who realized that the time had long since passed when the races could be genuinely separated, that it was futile and dangerous to try to tighten the screws of the caste system, and that the only hope for harmony and prosperity lay in casting aside race prejudice and dogma and attempting the task of making democracy work, though that entailed the relaxation of the industrial colour bar and the admission of civilized nonwhites to the franchise. More significant, perhaps, was the widening of the gulf between the whited and the nonwhites and the forging of closer links between the leaders of the African, coloured and Asiatic communities. Although an all-embracing antiwhite front was not yet completed, headway was being made in that direction during 1952, when many hundreds of persons deliberately went to jail for "passive resistance to unjust laws." A different type of evidence of the intensity of racial feelings was provided by violent riots by Africans against Indians in Durban in 1949 (with a death toll of 142) and against whites in Kimberley, East London and Port Elizabeth in 1952.

Meanwhile South Africa had been weakening some of its remaining links with the other commonwealth countries and embarrassing Britain by reviving its claim to incorporate Basutoland, Bechuanaland and Swaziland. Although a small South African air force was sent to serve with the U.N. forces in Korea, South Africa incurred much calumny at the annual sessions of the general assembly of the United Nations. As the 1953 election approached, the Nationalist party swallowed the Afrikaner party and asked for a further mandate to enable it "to save white South Africa." The election was held on April 15. The Nationalist party was again returned, with an increased majority of seats in the house of assembly. They held 94 seats, the United party 57 and the Labour party 5. There were also the three seats held by the native representatives. In the old house the Nationalists had held 86 seats, the United party 64 and the Labour party 6. These results meant that, in spite of their success, the Nationalists still lacked the two-thirds majority they needed if they were to remove the Cape coloured voters from the common roll.

POPULATION

Racial Groups and Distribution.—The South African people are divided into four groups-Europeans, natives, Asiatics and coloured. The distribution of these groups is shown in Table I. By Europeans is implied persons of European origin, although no absolute test has been found to detect former slight racial mixture. Of the European groups by far the largest are those of Dutch and British origin. With the Dutch are included comparatively small groups of settlers of French Huguenot and German origin. It is not possible to discriminate between the Dutch and British groups on a somatic basis; home language-Afrikaans or English—gives a rough approximation of the group proportions which are shown in Table V. By "native" is implied a member of the Bantu racial group. Asiatics are almost entirely of Indian origin. Coloured or "mixed" groups are those springing from the mixture of European and non-European groups, or of Bantu, Hottentot, Malay and Bushman mixtures.

The proportion between the four main groups remained fairly constant in the 20th century, as is shown by Table II.

The density of population (all races) varied in 1946 from a minimum of 14.63 per square mile in the Cape province to a maximum of 62.42 in Natal, the mean for the Union being 24.16,

made up of 19.14 non-Europeans and 5.02 Europeans.

The later increase of population was attributable mainly to excess of births over deaths and only slightly to immigration.

Table I -Distribution of Population, 1936-51

Group and date	Cape province	Natal	Orange Free State	Transvaal	Total
European 1936 1946 . 1951*	791,574 870,795 935,674	190,549 236,697 274,468	200,978 202,077 227,587	820,756 1,063,121 1,205,458	2,003,857 2,372,690 2,643,187

\*Preliminary census.

During the 15-year period 1937-51 the total net increase of the European population as a result of immigration over emigration was 60,230; that of the non-European population was 6,550.

Table II.—Percentage Analysis of Racial Groups, 1904-51

Year	European	Native	Asiatic	Coloured	Total Non-European
1904	21.6	67 4	2.4	8 6	78 4
1921 .	21.9	67.8	2.4	7.9	78.1
1946	20.8	68.6	2.5	8.1	79 2
1951	20.9	67 5	3.4	8.2	79 1

A noteworthy trend in the movement of population after the beginning of the 20th century was the disproportionate increase in urban population, as Table III shows.

Table III.—Comparison of Urban and Rural Population, 1904-46

Group and year	Uı	rban	Rural		
Group and year	Number	Percentage	Number	Percentage

1946	2,425,645	26.9	6,593,691	73.I	

Towns.—The principal towns of South Africa grew up as seaports (Cape Town, Durban, Port Elizabeth, East London) or as centres of mineral exploitation (Johannesburg, Kimberley) or as administrative and educational centres (Pretoria, Pietermaritzburg, Bloemfontein, Grahamstown). The largest agglomeration is on the Witwatersrand, where more than 1,500,000 people live in Johannesburg and the eight other reef municipalities. Cape Town with its suburbs comes next with more than 500,000. In 1951 there were eight cities and towns with more than 100,000: the composition of their populations is shown in Table IV. After these 8 come 12 towns with between 30,000 and 100,000 persons and 29 with between 10,000 and 30,000. The remainder are for

the most part small country towns or villages with populations

generally between 3,000 and 4,000 Europeans and about equal numbers of non-Europeans.

Language.—South Africa has two official languages, English

"Language.—South Africa has two official languages, English and Afrikaans. The latter is derived from the Dutch of the 17th century, which was brought out by the early settlers. The vocabulary is somewhat limited and the structure considerably simplified to meet the ordinary requirements of a rural population and to be intelligible to the Bantu and Hottentots in its service. The distribution of the English- and Afrikaans-speaking groups is shown in Table V.

TABLE V.-Proportions of English and Afrikaans Spoken, 10.16

	Language	Cape province	Natal	Orange Free State	Trans- vaal	Union	Per- centage
-	Afrikaans .	512,022	51,510	175,137	621,035	1,359,704	57 31

churches include the Nederduits Gereformeerde Kerk, with a European membership of more than 1,000,000, the Gereformeerde Kerk van Suid-Afrika and the Nederduits Hervormde Kerk, which together have a European membership of slightly more than 200,000. The (Anglican) Church of the Province of South Africa is divided into 15 dioceses; the seat of the archbishop is Cape Town. The Methodist Church is under the jurisdiction of the South African Methodist conference, which organizes seven districts and 305 circuits. The Roman Catholic Church in South Africa is organized under the Apostolic Delegation of Southern Africa. The seat of the apostolic delegate is in Pretoria.

Health.—The health of the European population of the Union compares favourably with that of other countries, the European crude death rate (1945–47) standing at 8.9 per 1,000, as compared with 10.2 in the United States, 10.6 in the Netherlands and 12.3 in England and Wales.

Of the notifiable-diseases, about 5,000 cases of amoebic dysentery occur annually, mainly among the natives of the eastern low veld, and a similar number of enteric or typhoid cases. Diphtheria is now reduced to about 2,000 cases, the greater number being European. The most serious disease is tuberculosis in its various forms, the native and coloured people being particularly susceptible. Leprosy is decreasing; in the institutions are about 2,000 cases; of these fewer than 100 are Europeans. Malaria is endemic in the eastern and northern low veld and is epidemic in some years over much of the Transvaal middle veld, but the DDT campaign against the anopheline mosquito is succeeding in many areas. Bilharziasis is serious in parts of the Transvaal, Natal and the eastern Cape province; in places 50% of the native population is infected. A National Bilharzia committee was formed to deal with the situation. Of the formidable epidemic diseases human plague and smallpox generally cause a few deaths annually; epidemics of typhus have occasionally been serious among the natives but their incidence is decreasing as a result of DDT and health education.

Housing.—In 1920 a Housing act was passed, empowering local authorities to borrow money from the government for the purpose of building houses of limited size or for lending to approved borrowers for building. A Central Housing board was set up to examine plans and to report on them to the administrator of the province concerned. By 1939 a large number of schemes was in operation, but World War II slowed up progress. Under the 1944 Housing Amendment act the Central Housing board was replaced by the National Housing and Planning commission, and an ad-

visory body, the National Housing council, was set up. The commission was given much wider powers than the Central Housing board and could build houses, buy and allocate materials and establish building research and regional planning branches. On Dec I, 1945, the Natal Housing board came into existence to fulfil in that province the functions performed in the rest of the Union by the National Housing and Planning commission. Under a new agreement between the government and the local authorities a new National Housing scheme was set up under which the government was to hear more of the loss on housing schemes than previously.

The pace of drift into the towns, particularly by natives, made the housing problem a difficult one in the Union. It was estimated that 154,000 additional houses were needed for natives in the towns in 1947. During the financial year ended March 1951 the Union spent nearly  $\mathcal{L}(S.A.)$  3,000,000 on native housing, and in June 1952 the minister of health, K. Bremer, said that, in the three years up to June 1951, 18,900 houses had been built for coloured and native people. European housing was also insufficient, and between the beginning of 1948 and April 1951 60,000 housing units were built by the National Housing and Planning commission, local authorities and private agencies.

Conditions of Labour.—In 1922 the first Apprenticeship act made provision for training South African youth in trades for which it had previously been necessary to bring workmen from abroad. The Industrial Conciliation act and the Wage act of 1937, the Shops and Offices act of 1939 and the Factories act of 1947 cover most industrial and commercial occupations and provide for the fixing of minimum wages, hours of work, etc., and also deal with industrial health.

Most skilled work is done by Europeans, though in the Cape there are many skilled coloured workers and Malays, and in Natal Indian businessmen and many Indian journeymen. Most unskilled and semiskilled work is done by native or coloured people, though the drift into the towns has made it necessary for many Europeans to be employed in unskilled and semiskilled work not previously open to them.

There was little unemployment in the Union after World War II.

Table VII.—Registered Unemployed, 1948-52

Date*	Total	White	Asiatic	Coloured

Education.—Education of European children is compulsory between the ages of 7 and 16, but a child who has passed standard VI is permitted to leave school provided he enters a regular occupation. For coloured and native children education is not compulsory, except under special circumstances. The number of schools and pupils (in brackets) for non-Europeans in the Union in 150 was: Asiatics, 227 (56,396); coloured 1,263 (205,949); native, 5,338 (747,026).

There are nine universities in South Africa. The University of South Africa now conducts courses for external students only and is an examining body for external degrees. There are also the Universities of Cape Town, of the Witwatersrand, Johannesburg (the two largest universities, each with between 4,000 and 5,000

students), of Stellenbosch, of Pretoria, of the Free State, of Natal, of Potchefstroom and Rhodes university, Grahamstown. With the last named is affiliated the South African native college, Fort Hare. The total number of students in the nine universities is about 20,000. In 1952 at the Universities of Cape Town and of the Witwatersrand there were 219 and 245 non-European students, respectively, who enjoy academic opportunities in the same classes as European students. At the University of Natal there were 224 non-European students accommodated in a separate college. At Fort Hare there were 399 students of which 350 were natives, 34 coloured and 15 Asiatic. (J. H. WN.)

### CONSTITUTION

By the provisions of an act of the British parliament (South Africa act, 1909), the colonies of the Cape of Good Hope, Natal, the Transvaal and the Orange River colony were united to form the Union of South Africa on May 31, 1910. Upon its formation these four colonies became the provinces of the Union, the Orange River colony being renamed the Orange Free State province. The colonial legislatures were abolished, provincial councils were set up with specified powers, which could be reduced or increased by the Union parliament, and provincial administrators replaced the colonial governors. The constitutional basis of the Union is contained in the South Africa act, 1909, as amended. The Union remained a member of the British Commonwealth, but its sovereign independence is assured by the British Statute of Westminster, 1931, and the South African Status of the Union act, 1934. In 1919 South-West Africa was assigned to the Union as a "C" mandate. Its inhabitants are now South African citizens. It has an administrator and a legislative assembly and is represented in the Union parliament in terms of the South-West African Affairs Amendment act, 1949. (See South-West Africa.)

The Executive and Legislature.—The government is vested in the queen but is normally administered by a governor general, a South African. He acts on the advice of ministers of state whom he appoints as the queen appoints her United Kingdom ministers; that is to say, government is by a cabinet possessing the confidence of a majority in the lower house of parliament. Ministers administering departments may not exceed 14 in number. A minister cannot hold office for more than three months unless he has a seat in parliament; he may sit and speak in either house but can vote only in the house of which he is a member.

Parliament, consisting of a senate and a house of assembly, has "full power to make laws for the peace, order, and good government of the Union." It may legislate on any topic and amend most sections of the South Africa act by bare majorities in each house sitting separately; but to amend the sections providing for the nonwhite franchise in the Cape province and the equal official status of the English and Afrikaans languages throughout the Union, bills must be passed by both houses sitting together and at the third reading must be agreed to by not less than two-thirds of the total number of members of both houses. During 1952 the appellate division of the supreme court gave two unanimous decisions to the effect that this procedure is still necessary.

The senate consists of 48 members. Its legislative powers are co-ordinate with those of the house of assembly, except in regard to the origination and amendment of money bills. A senator must be a South African citizen of white descent, aged 30 and, if an elected senator, must possess immovable property of the clear value of £500. In each province the members of the provincial council and of the house of assembly for that province elect eight senators by proportional representation; and in South-West Africa the members of the legislative assembly and of the house of assembly for that territory similarly elect two senators. Four senators are chosen to represent the Africans in specified areas by a complicated system of indirect election, in which chiefs, local councils and African advisory boards play a part. Five, including one for South-West Africa, are appointed by the governor general because of their special knowledge of "the reasonable wants and wishes of the coloured races"; and five others, including one for South-West Africa, are appointed by the governor general in his discretion. The four senators who represent the Africans serve

for five years and do not vacate their seats on a dissolution.

The house of assembly consists of 159 members, all of whom must be adult South African citizens of white descent. The constituencies are single and are delimited by a judicial commission every five years. One hundred and fifty seats are allotted to the provinces in proportion to their adult white population. By the 1952 delimitation, the Cape province returns 54 members, Natal 15, the Transvaal 68 and the Orange Free State 13. Within each province each of these constituencies contains an approximately equal number of voters, but a variation of 15% below or above the average is allowed for various factors, notably sparsity or density of population. Six seats are allotted to South-West Africa The African voters in the Cape province elect three members who hold their seats for five years and do not vacate them on a dissolution. A general election must take place at least every five years and all polls must be taken on the same day.

Apart from the three representatives of Africans, the house is elected by all the adult white South African citizens without distinction of sex in the four provinces and South-West Africa, and by a number of coloured men in Natal and the Cape province. In 1952 there were 134,761 white and 1,192 coloured voters in Natal and 546,364 white and 49,272 coloured voters in the Cape. These coloured voters have to possess literacy and property qualifications. Only male Africans who possess such qualifications may vote in the elections for the three whites who represent them in the Cape province. The Natives' Representative council which was set up with advisory powers in 1036 was abolished in 1051.

set up with advisory powers in 1936 was abolished in 1951.

The Judiciary.—The judiciary consists of a supreme court with local, provincial and appellate divisions. The judges are appointed by the governor general and are removable by him on receipt of an address from both houses of parliament requesting such removal on the ground of "misbehaviour or incapacity." Appeals lie to the appellate division from the local and provincial divisions of the supreme court and from the high courts of South-West Africa and Southern Rhodesia. Appeals from the supreme court to the privy council in England were abolished in 1950, except for appeals emanating from Southern Rhodesia. There is also an elaborate system of courts for civil cases between Africans. Such courts administer African customary law, with some infiltration of Roman-Dutch common law, and on points of law there is an appeal to the appellate division of the supreme court. The African is, however, subject to the ordinary courts in criminal cases and in disputes with whites.

Provincial Administration.—Provincial councils have the same number of members as the province returns to the house of assembly (but with a minimum of 25). Constituencies are single. The qualifications for electors are the same as for parliament, and any person qualified to vote is qualified to be a member of the council. Coloured men may therefore sit in the Cape provincial council and have in fact done so. The Cape provincial council also includes two members (whites) elected by the Cape African voters. Any member of a provincial council who becomes a member of either house of parliament thereupon ceases to be a member of such provincial council. Each provincial council continues for three years and is not subject to dissolution.

Provincial councils have original legislative authority as defined in the South Africa act and further authority as granted by parliament. Parliament may, however, remove any such powers; and provincial ordinances require the assent of the governor general and must not be repugnant to any act of parliament or the South Africa act. Primary and secondary education, hospitals, roads, municipal and charitable institutions are the principal subjects regulated by provincial ordinances. Formerly the provinces possessed considerable financial powers, but in the course of time they have been subjected to much greater control by the central government.

The head of the executive in each province is an administrator appointed by and responsible to the central government. He holds office for five years and is assisted by an executive committee of four persons elected by the provincial council from among its own members, or otherwise, on the proportional representation principle. The administrator, and any other member of the executive

committee who is not a member of the council, has the right to take part in the proceedings of the council, but has not the right to vote.

Law.—The basis of the common law of the Union is the Roman-Dutch law as it existed in the Netherlands at the end of the 18th century. This was the Roman law as put in its final form by Justinian and as interpreted during subsequent centuries and received into the Netherlands, with a large admixture of Dutch-Germanic custom. The authorities upon the common law in South Africa are the Dutch commentators, the statute law of the Netherlands, the decisions of the Dutch courts and, failing these, the corpus juris civilis itself.

English influence in South Africa led to a modification of the law by legislation and by judicial decisions and there was a considerable inflitration of English law. The law of contracts and of torts and the mercantile law, which in any event are derived from a comman basis, absorbed a fair amount of English law, though they are by no means identical with it. The same may be said of the criminal law. The law relating to shipping, insurance and negotiable instruments is practically identical with the English law, in some provinces because of legislation. The operation of the courts is based on the English system, and the rules of evidence and procedure are practically the same. In criminal cases trial by judge and jury, with the same formalities and safeguards as in England, is still allowed; but it is becoming far more common to have trial by judge and assessors. Minor offenses are dealt with by salaried magistrates. In civil cases there is no trial by jury.

There is, as might be expected, a vast difference between the English and South African systems in the law relating to property, persons and marriage and succession. As regards property, there is a comprehensive system of registration. A central deeds registry is kept and virtually all titles to land, as well as servitudes, mortgages and similar charges upon land, have to be registered against the title deeds. There is absolute freedom of testamentary disposition throughout South Africa. By the Roman-Dutch law, and in the absence of any antenuptial contract to the contrary, there is a complete community of property between husband and wife, subject to the sole control of the husband. The courts have, however, the right to interfere in case of any flagrant abuse of this power. Antenuptial agreements must in all cases be notarially executed and publicly registered. By the common law gifts between husband and wife during marriage are void as against creditors, but in 1953 there was the possibility that this rule might soon be abolished. Divorce is granted to either spouse for malicious desertion or insanity or when the other party is declared a habitual criminal by the courts.

See H. J. May, The South African Constitution, 2nd ed. (Cape Town, 1949); G. Wille, Principles of South African Law, 3rd ed. (Cape Town, 1949). (L. M. T.)

Police.—The whole Union and South-West Africa are policed by the South African police. On Dec. 31, 1951, the force consisted of 9,999 European members and 7,291 non-European. Police headquarters are at Pretoria.

In 1951 the first step was taken in a scheme whereby each native area was to be policed by members of the force belonging to the chief tribe of that area.

Defense.—Under the South African Defence act of 1912 (as amended in 1922 and 1932) every citizen of European descent must register when he is 17, and between the ages of 17 and 25 must undergo training for four years in the Active Citizen force. All citizens not accepted for this training must, when they are 21, enrol in the Rifle Commandos. The liability of non-Europeans to service may be decided by parliament.

The approximate strength of the permanent armed forces in 1952 was 1,000 officers and 9,000 men. The Active Citizen force was approximately 30,000 and the Rifle Commandos included approximately 100,000. (X.)

## ECONOMICS

Economic Development.—Three phases can be recognized in South Africa's economic development: the pioneer period of subsistence agriculture lasted until about 1870; from 1870 to 1914

the mining-agricultural phase succeeded, when gold and diamonds formed the basis of the economy and agriculture expanded to meet the needs of the increasing population; after 1914 this gave way to the mining-manufacturing phase in which mining provided much of the inland market and the overseas exchange for the rapid development of manufacture. Between 1914 and 1949 manufacturing industries passed from eighth to first place among the contributors to the national income, being responsible for more than twice the amount contributed by mining. In this period the number of factories increased from 4,000 to more than 14,000 and the gross value of manufacturing output from £(S.A.) 40,000,000 to £(S.A.) 675,000,000.

#### AGRICULTURE

Stock Raising.—Cattle are most numerous in the eastern part of the country where the summer rainfall exceeds 20 in. and where the natural vegetation is either grass veld or bushveld. The native cattle are probably descendants of the Sanga type, some branches of which are of exceptional hardiness and adaptability to the South African environment. The Afrikaner breed, developed by the Dutch settlers, is slow developing but very hardy and well-adapted to high temperatures. The introduction of European highly bred bulls was successful in the cooler regions but not in the hotter climates, to which these breeds are ill adapted. Most of the eastern areas are tick-infested, the main tick-borne diseases being east coast fever (or African coast fever), heartwater and gall sickness (or anaplasmosis), which are controlled by regular dipping.

Sheep farming is specially suited to the karroo type of vegetation in areas with a rainfall of between 10 and 15 in. and to the short-grass areas of the high veld. The most important type of sheep in the Union is the Merino, of which there were in 1950 about 20,00,000. The export of wool in 1951 amounted to 194,-000,000 bl. valued at £(S.A.) 79,000,000. Nonwoolled sheep, numbering about 5,000,000 in 1950, include native and Afrikane fat-tailed and fat-rumped breeds together with introduced Blackhead Persians, English mutton breeds and a few thousand Dutch Tesels, German Merinos, French Rambouillets and 1le de France. An important later development was the introduction, from South-West Africa, of the Karakul, of which there were about 1,500,000 in the Union in 1951.

Goats are kept in almost all parts of South Africa but the main breeding areas are in the Great and Little Karroos where the Angora produces most of the mohair for export. Between 2,000,-000 and 3,000,000 lb. of mohair are produced annually.

Horse breeding, once a flourishing and prosperous industry in South Africa, declined because of horse sickness and the increasing mechanization of transport. After World War II, however, an increasing interest was taken in the industry and four horse-breeders' associations were formed. Stud services were set up at government institutions, agricultural colleges and experimental stations. The best areas for horse breeding are the western Free State, the higher areas of the northeastern Cape province and the southwestern Cape. Donkeys and mules are bred and used in most parts of the country; the mule suffers from horse sickness, but less than the horse. Ostriches are bred mainly in the Little Karroo. In 1913 about 1,000,000 birds produced about 1,000,000 lb. of feathers, worth £(S.A.) 3,000,000. The following slump in

TABLE IX .- Number of Stock in the Union, 1950

1947 figure. †1946 figure. ‡Europeans only,

feathers resulted in the almost complete abandonment of ostrich breeding, but after about 1945 the industry revived.

Arable Farming.-Two distinct natural regions suited to agriculture can be recognized: the part of the summer rainfall region with more than about 20 in. of rain, and the winter rainfall region with more than about 10 in. Elsewhere cultivation on any considerable scale must be on the basis of irrigation.

In the summer rainfall zone by far the most important crop is maize, which is grown to some extent almost everywhere to the east of the 20-in. isohyet. Topography, rainfall and temperature combine to give greatest importance to the southern Transvaal and the northeastern Free State, an area commonly known as the "maize triangle," with its apexes at Ladybrand in the south and at Lichtenburg and Ermelo. This area produces about 60% of the Union's total maize crop, which varies from about 2,000,000 to 3,000,000 short tons a year. The yield varies from about 200 lb. to the acre in some of the native areas to about 1,000 lb. on European farms in the maize triangle. The introduction of hybrid varieties is expected to increase production by at least 25%.

Wheat is the main cereal in the southwestern Cape, but its production is increasing in the eastern Free State and the southern Transvaal where late summer rains or the availability of water for irrigation make a winter crop possible. The total annual production in the Union fluctuates between about 250,000 and 500,000 short tons. Oats and barley are also grown in the wheat area. The faveurite crop of the native is kaffir corn (sorghum), which does well in the summer rainfall area where the rainfall is too low or too

unreliable for maize.

In the Natal coastal area sugar cane became almost a monoculture. The cane fields extend from Port Shepstone in the south to the Pongola valley in the north, comprising altogether about 800,000 ac., of which about half carries cane in any year and a quarter is reaped. The yield of cane in 1950 and 1951 was about 5,500,000 short tons.

Fruits of various kinds have become increasingly important. The winter and summer rainfall areas form fairly distinct areas of production. In the Mediterranean climate of the southwestern Cape, the vine flourishes in the lower areas and deciduous fruits of many kinds in the higher valleys and basins. In the eastern part of the Union, generally under irrigation, citrus varieties form the main fruit crops, with subtropical fruits such as the papaw, banana, pineapple, avocado, granadilla and litchi in the low-veld areas.

The area under irrigation in South Africa is about 600,000 ac. Eight irrigation schemes are larger than 20,000 ac. and the largest, the Vaal-Hartz scheme, has an actual irrigated area of 55,000 ac .-a potential area of nearly 90,000 ac. Obstacles to irrigation include the great variability in the flow of most of the rivers and the high percentage of silt carried in suspension.

# INDUSTRIES

In the Union manufacturing development was stimulated by the mineral industries of which gold mining is of greatest importance. In 1950 gold to the value of £(S.A.) 145,000,000 accounted for about 75% of the Union's mineral production, the consumption of local "stores" being of the order of 35% of the total production costs. In 1950 coal (£[S.A.] 14,750,000) and diamonds (£[S.A.] 14,500,000) accounted for about 15% of the Union's mineral production, and copper, asbestos and manganese for nearly 7%.

Manufacturing industries were stimulated by the difficulty of obtaining overseas manufactures during World War II. The most important development was in iron and steel manufacture; the government-sponsored South African Iron and Steel Industrial corporation (I.S.C.O.R.) was producing in 1952 about 600,000 tons of steel and 800,000 tons of pig iron at Pretoria, and the new works at Vanderbijlpark, near Vereeniging, were producing at the rate of about 500,000 tons of steel a year with a capacity of double this amount. Other spectacular developments include the growth of textile manufactures. Imports of textiles in the immediate postwar period averaged about £(S.A.) 50,000,000 annually. By 1950 eight cotton mills had come into operation in the Union, employing 3,600 workers of whom 3,400 were native males. It was estimated that by 1953 the Union would be supplying one-third of its cotton piece-goods requirements. Woollen factories include nine worsted plants and four fully integrated firms capable of producing three-quarters of the Union's requirements. About 4,000. ooo lb. of the Union's tops can now be combed in the country, but the greater part of the raw wool must still be exported. In the Good Hope Textile corporation's factory at Zwelitsha, near King William's Town, natives in the Ciskeian native reserves are trained in the weaving, spinning, bleaching, dyeing, printing and finishing processes.

In 1949 of the 17 classes of manufacture in the Union the net outputs for private industries included metal engineering, £(S.A.) 58,000,000; clothing and textiles, £(S.A.) 29,000,000 building, £(SA.) 24,000,000; chemicals, £(S.A.) 19,000,000; printing, £(S.A.) 18,000,000; and vehicle making, £(S.A.) 17,000,000. Stonework, heat, light and power, leather and woodworking follow, the total net value of all private industries being £(S.A) 265,000,-000, the gross value £(S.A.) 610,000,000. The corresponding values for public industries were £(S.A.) 33,000,000 and £(S.A.) 65.000,000.

Of the 562,000 wage earners in manufacturing industries in 1948, 28.8% were Europeans, 54.7% natives, 3.2% Asiatics and 13.2% coloured. The total remuneration of these employees was £(S.A.) 115,000,000. This may be compared with the total number of 455,000 employed in mining, at a remuneration of £(S.A.) 52,000,000.

### TRADE, TRANSPORT AND FINANCE

Trade.—Table X shows the Union's principal imports and exports. The South African customs are of a protective character; based on a "three line" tariff, they provide for minimum, intermediate and maximum duties. Of the conventions and trade treaties concluded before World War II those which were still in force in 1953 and which affected the Union's industrial development were preferential and reciprocal trade agreements with the United Kingdom, Canada, Australia and the British colonies, and temporary commercial agreements on a most-favoured-nation basis with cer-

tain European countries and with Egypt and Brazil. During World War II a most-favoured-nation agreement was concluded with Angola. The postwar situation was determined largely by the 1947 General Agreement on Tariffs and Trade (Geneva), which covered 23 countries including the Union. After 1947 the Union entered into a Customs Union (Interim) agreement with Southern Rhodesia (April 1949) which aimed at the ultimate re-establishment of a complete customs union between the two countries. This agreement had the effect of introducing competition in certain of the manufacturing industries of the two countries, where costs are differentially affected by the greater employment of European labour in the Union.

Transport.-The railway system was designed mainly to connect the ports with the inland mining and manufacturing centres. The dominating inland area is the southern Transvaal, including the Witwatersrand and the growing manufacturing localities from Vereeniging in the south to Pretoria in the north. The standard railway gauge is 3 ft. 6 in. In 1951 the state railways owned more than 13,500 mi. of line, carried 63,000,000 tons of goods and 243,-000,000 passengers. In the same year harbours (falling also within

the Railway administration) landed more than 7,500,000 tons of ourgo and shipped 5,000,000 tons. Airways carried 141,000 passengers between inland and coastal centres. Motor services ran on 26,000 mi of roads, carrying 15,000,000 passengers. The electrification of the railways between Durban and the Transvaal border had by 1952 accelerated the traffic to the Rand, and the electrification of the Belleville (Cape Town)-Touws River line, and the cutting of the Hex River Mountains tunnel was expected to accelerate services from the southwest to the interior.

Railway rates, designed to assist inland economic development and the distribution of minerals from inland mining areas, are fixed arbitrarily by the Railway administration. The transport of goods and passengers by road is controlled by the National Transport commission and local Road Transportation boards. One effect of this control is the elimination of the competition of private road transport with railway transport.

Finance.—The monetary unit is the South African pound, which is at par with the pound sterling.

The relative powers of the provinces and the Union over finance were mainly defined in the South Africa act of 1909 and in the Financial Relations act of 1913, modified by later legislation.

SOUTH AFRICAN LITERATURE. The earliest writings about South Africa date back several centuries, but South African literature is of more recent origin. After a difficult start in its development from the Dutch language, Afrikaans developed a strong literature, and a review of South African literature must be divided into that written in English and that in Afrikaans.

### ENGLISH

Various reviewers have held that English literature in South Africa has followed the main lines of development in the rest of the English-speaking countries. This view must be accepted with reserve; it is true that many early writers were British and that most younger writers left the country to work as part of other traditions, but South African literature proper has, none the less, individual characteristics.

In poetry this individuality is revealed by an indigenous subject matter and the use of imagery and diction that are characteristically South African. The first poet of note was Thomas Pringle (Ephemerides, 1828; African Sketches, 1834). After a considerable lapse there were William Charles Scully (Wreck of the Grosvenor, 1886; Poems, 1892; By Veldt and Kopje, 1907; Voices of Africa, 1944), Francis Carey Slater (Footpaths Thro' the Vela, 1905; The Sunburnt South, 1908; Settlers and Sunbirds, 1919; The Karroo, 1924; Veld Patriarch, 1949), Arthur Shearly Cripps (Lyra Evangelistica, 1909; Pigrimage of Grace, 1912; Lake and War, 1917) and Charles Murray (Hamewith, 1909; A Sough of War, 1917; In the Country Places, 1920). These are poets of the older school and their verse shows no particular talent or individuality other than this "South African" quality. Cullen Goulds-

bury (Rhodesian Rhymes, 1909; Songs out of Exile, 1912; From the Outposts, 1914), a poet and novelist of great promise, died prematurely.

Roy Campbell wrote notable South African poetry in *The Flaming Terrapin* (1924), *The Wayzgoose* (1928), *Adamastor* (1930), *Flowering Reeds* (1933) and many others. William Plomer (*Family Tree*, 1928, and others) also became prominent. Later poets include Frank Prince, R. M. Titlestad, Anthony Delius and Guw Butler.

Anthologies include Treasury of South African Poetry (edited by E. H. Crouch, 1907 and 1909), Centenary Book of South African verse (edited by Francis Carey Slater, 1925 and 1945) and South African Poetry (edited by Roy MacNab and Charles Gulston, 1948).

The South African novel also has characteristics which differentiate it from other novels in English. Few of the important novels are free from a topic peculiar to South Africa. Notable exceptions are Olive Schreiner's Story of an African Farm (1883); Sarah Gertrude Millin's Mary Glenn (1925), Sons of Mrs. Aab (1931) and What Hath a Man? (1938); Ethelreda Lewis' Harp (1924); and Elizabeth Charlotte Webster's Expiring Frog (1946). Olive Schreiner's Story of an African Farm has the distinction of being the first novel of note to come from Africa and, despite some failings, is a work of merit. Her later works, Trooper Pêter Halket of Mashonaland, From Man to Man and Undine, fell below its standard.

The most popular subject for novels is the trials of the "mixed" or coloured people, who have been developed by centuries of miscegenation and are isolated from both Africans and Europeans. Sarah Gertrude Millin (God's Stepchildren, 1924; King of the Bastards, 1950; Burning Man, 1952) became the major writer on this theme, although William Plomer in his short stories I Speak of Africa (1927), Laurens van der Post in In a Provunce (1934) and Perceval Gibbon in Souls in Bondage (1904) wrote with insight. Peter Abrahams, a coloured writer, produced some impressive work (Dark Testament, 1942; Song of the City, 1945; Mine Boy, 1946; Return to Goli, 1953).

The native formed the subject of hundreds of adventure stories and "ethnographical" novels, but the best work was done in books showing the difficulties of the native people in society. Cullen Gouldsbury (God's Outpost, 1907; Tree of Bitter Fruit, 1910), William Plomer (Turbott Wolfe, 1925), Sarah Gertrude Millin (Coming of the Lord, 1928; Herr Witchdoctor, 1941), William Charles Scully (Daniel Vananda, 1923), Alan Paton (Cry, the Beloved Country, 1949) and J. Grenfell Williams and Henry May (I am Black, 1936) produced a unique and sometimes powerful body of work.

Other novels include historical works by Stuart Cloete (Turning Wheels, 1937; Watch for the Dawn, 1939; Hill of Doves, 1941) and Dorothea Fairbridge (That Which Hath Been, 1910); A. A. Smith's Trader Horn (1927–28); Percy Fitzpatrick's charming dog story Jock of the Bushveld (1907); Horace Rose's Golden Glory (1915); and Daphne Muir's Virtuous Woman (1920).

Pauline Smith's Little Karroo (1925) must head any list of South African short stories. William Westrup's Old McBein (1937) and Treek Chain (1929) and Ernest Glanville's Kloof Yarns (1896), Tales From the Veld (1897) and Claw and Fang (1933) are outstanding for their description of animal and veld. Among later books, Herman Charles Bosman's Majeking Road (1947) and Nadine Gordimer's Face to Face (1949) revealed remarkable gifts.

Travel books were the earliest books written about South Africa, and the works of Thomas Baines, John Barrow, William John Burchell and David Livingstone became well known. In the popular travel book by Laurens van der Post, Venture to the Interior (1952), the scene is Nyasaland, but it seems that the writer's understanding of the country has its origin in his native soil. In biography an extensive literature gathered round the names of Cecil Rhodes, L. S. Jameson, Louis Botha and J. C. Smuts, the best work being done by Sir Thomas Fuller, Sarah Certrude Millin, Ian Colvin, Earl Buxton, J. Crafford and H. C. Armstrong. The letters of Lady Anne Barnard (South Africa a Century Ago, 1901)

give a vivid account of the years 1797-1801 at the Cape.

No significant drama in English had been produced in South
Africa by mid-20th century

(J. P. L. S.)

### AFRIKAANS

Afrikaans, one of the youngest members of the Teutonic group, is the language used by the descendants of Dutch, German and French colonists who settled in South Africa after 1652 and before the British occupation in 1806. The 17th-century dialects of the Netherlandish province (South) Holland form the linguistic basis of Afrikaans; but, although the Afrikaans vocabulary is even today almost identical with the original stock, the grammatical struc-ture has been much simplified. The Afrikaans noun has no grammatical gender, has lost all inflectional forms but the singular and plural, uses one form of the verb for all persons, forms its tenses with modal words and has obliterated the difference between the weak and strong declension. Afrikaans structure is, therefore, even more analytical than that of English. This development is mainly a result of an early lack of the conserving influence of schools and literature, new surroundings and occupations and the incorporation of German and French immigrants. There is every reason to believe that Afrikaans reached its modern form not much later than 1750.

Until the second decade of the 20th century Dutch was still used in South Africa for literary and official purposes. Toward the middle of the 19th century Afrikaans was used in letters in some newspapers and in a few propaganda pamphlets. In 1875 a society, Die Genootskap vir Regte Afrikaners, was founded to translet the Bible into Afrikaans and to foster the use of the language officially. The society founded a magazine and newspaper and started a printing press, but of the literary production of the period 1860–1900 only J. L. Cachet's didactic stories Die Sewe Duivels and S. J. du Toit's historical novel Die Koningin van

Skeba are still read.

The South African War saw the end of the society, but it also saw the birth of an entirely new spirit in the movement for the recognition of Afrikaans. The old phonetic orthography was discarded in favour of a spelling more closely related to Dutch; new writers and scholars, better equipped for the task, took the lead; new journals were founded. Die Afrikaanse Akademie was founded in 1909. As a result of all these activities Afrikaans was adopted as a medium of instruction in schools (1914), university professorships in Afrikaans were instituted, and by 1924 all the Afrikaans churches had adopted Afrikaans as their official language. In 1925 Afrikaans was officially recognized by the entire country. The complete Afrikaans version of the Bible was published in 1937. The first volume of the Afrikaans dictionary, begun in 1925, was completed in 1950. After 1935 an everincreasing number of Afrikaans journals, magazines and newspapers was established.

A literature distinctly Afrikaans in colour and sentiment grew out of the experience of the South African War. The first group of poets of real merit whose poems arose from this experience were Eugène N. Marais, Jan F. Celliers (Die Vlatte, 1908; Marijie, 1911), J. D. du Toit (Totius—By die Monument, 1908) and C. L. Leipoldt (Oom Gert Vertel E. A. Gedigte, 1911). Largely because of the national spirit of its poetry Afrikaans came to be recognized as the cultural language of the country within an ex-

tremely short space of time.

Advances in the field of prose were soon made. G. S. Preller and C. J. Langenhoven, both keen supporters of Afrikaans, D. F. Malherbe and Jochem van Bruggen were still largely concentrating on the national experience during the war, but they soon turned their attention to the realistic novel and made a sound contribution toward the beginning of an Afrikaans prose style (Malherbe, Die Meulenaar, 1916; Bruggen, Ampie, a trilogy, 1924—2). A. A. Pieunaar's masterly novelettes on wild life in the African jungle, Uit Ourwoud en Vlakte (1921), belong to this period.

Meanwhile a new generation of poets had arisen who were mainly concerned with the impact of modern science and technology on a mainly agrarian and patriarchal culture and religion. Consequently the stress was shifted from national to personal ex-

perience. Toon van den Heever especially, in his Gedigte (1919), succeeded in embodying his doubt and his rebellion against th; biblical tenets of his people in his poems. Although it is characterized by differences of outlook, style and interests, the poetry of the following is actually part of this period: T. J. Haarhoff, Die Liefde van Catullus (1933); S. J. du Toit, Tussen die Dae (1947); A. G. Visser, Gedigte (1925) and Die Purper Iris (1930).

About 1925 a new group emerged to dominate the literary scene for the next decade. The most marked advance was made in the field of the novel and the short story. The realistic and the social novel was much favoured. The dominating figure from that time was C. M. van den Heever (Op dee Plaas, 1927; Droogte, 1929; Somer, 1935; Laat Vrugte, 1939; Die Held, 1948; and a biography, Generaal J. B. M. Hertzog, 1943). Other prominen authors of the period were C. H. Kühn (Toings, a trilogy, 1934-44; Klaradynstraat, 1947), J. van Melle (En Ek is Nog Hy, 1942). G. C. and S. B. Hobson (Kees van die Kalaharie, 1979; Buks, 1933), Holmer Johanssen (Die Onterfdes, 1944), P. J. Schoeman (Op die Groot Spore, 1942) and G. H. Franz (Moeder Poulin, 1946). Those members of this group who were also pets—Van den Heever (Deining, 1932; Aardse Vlam, 1938) and I. D. du Plessis (Stryd, 1935; Kwatryne, 1941)—might be regarded as the transition to the next generation, the poets of 1935.

In the poetry of this latter group national experience is at last entirely ignored and the poems centre on the feelings of the individual. The old rhyming verse is discarded in favour of modern blank verse. The new form of poetry passed its zenith soon after 1950, but until then it dominated the field. The outstanding members of the group were N. P. van Wyk Louw (Alleenspraak, 1935; Die Dieber Reg, 1939; Raka, 1940), D. J. Opperman (Heilige Beeste, 1945; Negester Oor Nineve, 1947; Engel uit die Klip, 1951) and W. E. G. Louw (Die Ryke Dwaas, 1934). The younger poets differed from the above in their lyrical excellence. They include Uys Krige (Oorlogsgedigte, 1942; Hat Sonder Hawe, 1949), Elizabeth Eybers (Belydenis in die Skemering, 1936; Die Stil Avontuur, 1939), S. J. Fretoria (Vonke, 1943; Inkeer, 1940) and Olga Kirsch (Mure van die Hart, 1948).

There are few Afrikaans plays, but dramatists of a high literary standard include C. L. Leipoldt (Die Hebs, 1923), J. F. W. Gross-kopf (Drie Eenbedryvee, 1936; Die Klépdolk E. A. Kort-Spele, 1941), H. A. Fagan (Die Ouderling, 1934) and Uys Krige. A younger dramatist than these, W. A. de Klerk, came to the fore with his play Die Jaar van die Vuuros; it received the national prize for drama during the Riebeeck centenary of 1952 as well as the prize of the Suid-Afrikaanse Akademie, the award in both cases being shared with G. Beukes's As Ons Eers Getroud Is.

See C. M. van den Heever and P. de V. Pienaar (eds), Kultuurgeskiedenis van die Afrikaner, 3 vol., a symposium with exhaustive lists of books (Cape Town, 1945-50).

SOUTH AFRICAN WAR, 1899-1902. The South African War may be divided into three distinct periods. The first comprises the Boer invasion, ending with the relief of Ladysmith on Feb. 28, 1900. The second ended in Oct. 1900 with the flight of Pres. Paul Kruger. The third consisted of guerrilla warfare on the part of the Boers, met by the blockhouses and punitive columns of the British, which operations were in force until May 31, 1902, when peace was ratified at Pretoria.

Operations in Natal.—The war opened with the investment of Mafeking by a Transvaal force under P. A. Cronje and the envelopment of Kimberley by Free State commandos under C. J. Wessels. But these were minor operations. The main Boer effort was made in Natal, where the forces were commanded by P. J. Joubert, while Lieut. Gen. Sir George White was the British commander in chief. The northern part of Natal presented two faces of a triangle to the two republics, the short base being formed by the Tugela river. Close to the head of the triangle at Dundee and Glencoe was posted a small British force under Maj. Gen. Sir W. Penn-Symons. Against this force there advanced a Boer force under Lukas Meyer from the east and, more slowly, the foremost portion of the main Boer army from the north, while at the same time other Transvaalers descended upon the railway between Glencoe and Ladysmith, and

the Free Staters from the passes of the Drakensberg advanced toward Ladysmith, the British centre of operations at which the reinforcements from India gathered. On Oct. 20, 1899, the Dundee brigade vigorously and successfully attacked Talana hill and drove back Lukas Meyer, but Penn-Symons was mortally wounded, and 226 officers and men were killed and wounded. Half the mounted men lost their way in attempting to pass the enemy's flank and were taken, and the brigade, threatened to its left rear by Joubert's advance and by the force that had seized the railway, escaped only by retreating upon Ladysmith, where it arrived in an exhausted state on Oct. 26. Meanwhile Sir George White had discovered the Boer force on the railway, and, though anxious because of the advance of the Free Staters, on Oct. 21, stimulated by the news of Talana, he sent out a force of all arms under Gen. J. D. P. French to drive the Boers from Elandslaagte and so to clear Penn-Symons' line of retreat. This was accomplished by French and his subordinate, Col. Ian Hamilton, in the action of Elandslaagte on Oct. 21 (British losses, 258). But on Oct. 22 the Free Staters' advance caused the victorious force to be recalled to Ladysmith, and the third action north of that town, Rietfontein (Oct. 24), was only a demonstration to cover the retirement of the Dundee force. By Oct. 29 all the British forces at the front and their reinforcements had fallen in on Ladysmith, which the Transvaalers on the north and east and the Free Staters on the west side began to invest. Before the junction of the two allied wings was complete Sir George White attempted by a general attack to break up their line. The result of this decision was the battle of Lombard's Kop, outside Ladysmith, in which the whole of the available British force was engaged. The engagement was disastrous to the British, who had undertaken far too comprehensive an attack, and the Natal field force was obliged to fall back upon Ladysmith with the loss of 1,500 men, including a large number of prisoners belonging to the left column, who were cut off at Nicholson's Nek and forced to surrender by a mixed force of Transvaalers and Free Staters under Christiaan De Wet. Two days later Ladysmith was isolated, but not before French had escaped south by train, and the naval authorities had been induced to send into the town a naval brigade with large guns, able to answer Joubert's artillery.

Buller's Arrival.-Gen. Sir Redvers Buller, who had been appointed to the supreme command in South Africa as soon as it was perceived that war was imminent-his force being one army corps in three divisions, the divisional generals being Lord Methuen, Sir W. Gatacre and Sir C. F. Clery-arrived in Cape Town, ahead of his troops, on the day following Lombard's Kop. The situation which presented itself was delicate in the extreme. In Natal practically the whole of the available defense force was swallowed up by the steady success of the invasion; on the western frontier two British towns were isolated and besieged; and Boer commandos were on the point of invading Cape colony, where the Dutch population seemed on the verge of rebellion. The army corps was about to arrive, practically as a whole unit, in South Africa; but it was evident that the exigencies of the situation, and the widely divided areas of invasion, would at least defer the execution of the plan which had been formed for an invasion of the Orange Free State from Cape colony. The first duty was to effect the relief of the British forces which had been rendered immobile, and another duty imposed by political circumstances was to relieve Kimberley (where Cecil Rhodes was), while the prospect of rebellion forbade the complete denudation of the central part of the colony. Thus Buller had no choice but to disintegrate the army corps. Clery and some brigades were sent to Natal; Gatacre with less than a brigade, instead of a division, was dispatched to Queenstown, Cape colony; while Lord Methuen, with a division, was sent off to relieve Kimberley. As November wore on, British prospects did not improve. Cape colony was invaded; while in Natal a flying column of Boers, pushing down from the Tugela, for a short time isolated the newly arrived force under Gen. H. Hildyard, which opposed Joubert's advance on Pietermaritzburg at Estcourt. The situation in Natal seemed so serious that on Nov. 22 Buller left Cape Town and sailed for Durban.

Failures of Methuen and Gatacre.-In the meantime Methuen had begun his march to the relief of Kimberley. He encountered resistance at Belmont on Nov. 23, but drove the Boers out of their strong positions. Two days later he won another action at Enslin. Still persevering he moved on to the Modder, where he was seriously opposed by J. H. De La Rey and Cronje, the latter having posted down from Mafeking with 2,000 men and arrived on the previous night. The Boers, who held a river line, kept the British attack at bay all day, but eventually fell back, relinquishing the position after dark, as their right had been turned by Sir Reginald Pole-Carew's brigade. It was a long and wearing fight, in which the British lost 485 killed and wounded, and, what was more serious, Methuen (himself wounded) found that his force had exhausted its forward momentum and that he would have to collect supplies and reinforcements on the Modder before fighting his next battle. The extent of the operations and the gravity of the situation now began to be felt in England; every available man was called up from the reserves, and the war office made what at the time seemed adequate provision for the waste which it was seen would occur. On Nov. 30 the mobilization of a sixth division was ordered, offers of colonial aid were accepted and every facility was provided for local recruiting. On Dec. 10 Gatacre essayed a night march and attack upon the Boer position at Stormberg, and, misled by his guides in unknown ground, Was himself surprised and forced to return with a loss of 719. On the following day Methuen delivered an attack upon Cronje's position between the upper Modder river and the Kimberley road, a line of koppies called Spytfontein and Magersfontein. In a night attack on Magersfontein hill the Highland brigade was caught under heavy fire while still in assembly formation and lost its general, A. J. Wauchope, and 750 men, and in the battle by day which followed, the total losses amounting to about 950. Buller had collected at Chieveley in Natal a mounted brigade and four infantry brigades.

Buller's Failure; Lord Roberts Sent Out .- On Dec. 15 Buller made his effort and failed. Behind the Tugela at Colenso (q,v) were Louis Botha's forces covering the siege of Ladysmith, and, imperfectly acquainted with the lie of the ground, Buller sent a force to turn Botha's left, in conjunction with a frontal attack. But the flank attack became entangled in mass in a loop of the river and suffered heavily, and two batteries that formed part of the frontal attack came into action within a few hundred yards of unsuspected Boer trenches, with the result that ten guns were lost, with about 1,100 men. Buller then suggested to White the surrender of Ladysmith, believing this to be inevitable and desiring to cover White's responsibility in that event with his own authority; but White replied that he did not propose to surrender, and the British cabinet, aware of Buller's despondency, appointed Field Marshal Lord Roberts to the supreme command, with Maj. Gen. Lord Kitchener as his chief of staff. As the formation of a seventh division practically drained Great Britain of trained men, a scheme for the employment of citizen soldiers was formulated, resulting in the dispatch of imperial yeomanry and volunteer contingents, which proved one of the most striking features of the South African campaign. Pending the arrival of Roberts and reinforcements, the situation in South Africa remained at a deadlock: the three besieged towns-Mafeking, Kimberley and Ladysmith-merely held their own. In northern Cape colony, French, with two cavalry brigades, kept at arm's length a superior force of the Boers in the vicinity of Colesberg. On Jan. 6, 1900, the Boers tried to storm Ladysmith. The garrison, though weakened by privation and sickness, made a stubborn resistance, and repulsed the attack at Caesar's Camp and Wagon hill with severe loss to the Boers, itself having 500 casualties.

Roberts arrived in Cape Town on Jan. 10, 1900. His first duty was to create a field army out of units in Cape colony. Buller essayed a second attempt to cross the Tugela, by turning the Boer left. But the upshot of several days' fighting was the retreat of the British. They had penetrated the Boers' right centre by the seizure of Spion Kop (q.v.), but the force there became the target for the concentrated attacks of the Boers, and, after suffering heavily, was withdrawn (Jan. 24, 1000).

By Feb. 1 Roberts had matured his plans; on Feb. 3 he ordered a demonstration against the right of the Boer position at Spytfontein-Magersfontein to cover the withdrawal of French's cavalry from before Colesberg, and the concentration of his army at Modder river, disregarding another setback in Natal to Buller, who had against Roberts' advice made a third attempt to relieve Ladysmith and failed to make good the purchase which he secured across the Tugela (Vaal Krantz).

Roberts' Advance.-Roberts' plan was first to concentrate to his left, taking every measure to induce the Boers to believe that the original scheme of invasion by the centre would now be resumed, and in this purpose he succeeded so well that his field army with the necessary transport for a cross-country march was assembled between the Orange and the Modder without serious mishap. Cronje at the new centre of gravity was not reinforced, all available Boers drawing down toward Colesberg. The concentration effected, Cronje still believed that the relief of Kimberley was the object of the gathering behind the Modder river and therefore held on to his Magersfontein koppie. The relief of Kimberley was indeed urgent, for dissensions between Rhodes and the military authorities had become acute But to this part of the task only the cavalry division assembled under French was assigned. The army itself was to force Cronje into the open and then advance on Bloemfontein from the west. Roberts began his operations on Feb. 11. French started from Ramdam (near Graspan) eastward on that day, intending to make a wide sweep round Cronje's immobile army. Skirmishing with De Wet in the first stages of their ride, the cavalry brigades crossed the Modder at Klipdrift on Feb. 13. Cronje sent only detachments to oppose them, but these detachments were broken through by a sword-inhand charge of the whole division, and Kimberley was relieved on Feb. 15. The infantry, meeting with great difficulties in its crossing of the Riet at Waterval because of the country and its own unwieldy transport, followed 11 to 2 days later. But Cronje had now realized his danger and slipped away westward behind French and in front of the leading infantry at Klipdrift. These were deflected by Kitchener westward to follow up the Boer rearguard, and after some delay the remainder of the infantry, at first fronting northward, swerved westward likewise, while French from Kimberley, with such of his men as he could mount on serviceable horses, headed off Cronje in the northwest. The result, after one premature and costly assault on Cronje's lines had been made by Kitchener, was the surrender of 4,000 Boers at Paardeberg (q.v.) with their leader on Feb. 27, the anniversary of Majuba. At the same moment came in news at last of the relief of Ladysmith.

Relief of Ladysmith .-- It was part of Roberts' purpose to relieve the pressure in Natal by his own operations. Buller began his fourth advance on Feb. 14, and though this was checked the foothold gained was not abandoned, and a fifth and last attempt, Pieter's hill (q.v.), was successful. Ladysmith (q.v.) was relieved on Feb. 28. It had fared worst of all the beleaguered garrisons, and its 22,000 inhabitants were almost at their last gasp when relief came. The casualties from shell fire had been few, but those from sickness were very heavy. Buller's operations, too, had cost at Colenso 1,100 men, at Spion Kop 1,700, at Vaalkrantz 400 and now in the last long-drawn effort 1,600 more-more than 5,000 in all. But the tide of war had changed. The Natal invaders fell back to the mountains which enclosed the north of the colony; Olivier and Schoeman retired from Cape colony; and the presidents of the republics hinted at status quo before the war. These proposals were rejected by Lord Salisbury.

Capture of Bloemfontein.—The surrender of Cronje and the relief of Ladysmith for the time being paralyzed the Boer resistance. Two half-hearted attempts were made early in March, at Poplar Grove and Driefontein, to stem Roberts' advance upon Bloemfontein, President Kruger himself arriving on the scene to give confidence to his burghers. But on March 13, 1900, Roberts' army marched into the Free State capital, this in spite of the fact that much transport collected at Ramdam had been cut off by De Wet.

It was only on March 29 that the new railway communication recommenced to feed the army. In the meantime rebellion had broken out in the Prieska district of Cape colony but was promptly quelled by Kitchener. The enforced halt at Bloemfontein was unfortunate for the British; it not only resulted in a bad outbreak of enteric but also gave the Boers time to recuperate, and by the beginning of April they again took the initiative. death of their commandant general, Piet Joubert, on March 28. seemed to mark a change in the fortunes of the Republican army, De Wet, who had first come into prominence as the captor of Roberts' convoy at Waterval and who was now operating east and southwest of Bloemfontein in order to counteract the influence of Roberts' numerous flying columns which rode hither and thither offering peace to the burgher, added to his laurels by ambushing R. G. Broadwood's mounted brigade and horse artillery at Sannah's Post, just outside Bloemfontein, on March 31. Four days later he reduced a detachment at Reddersburg, and then went south and invested a mixed force at Wepener, which was relieved after ten days by Gen. A. Hunter's Ladysmith division.

Relief of Mafeking .- On May 11 Roberts and his army moved northward upon the Transvaal capital, Pretoria. A flying column on May 17 relieved Mafeking, where Col. R. Baden-Powell had throughout shown an unconventional gaiety. The same day the Natal field force under Buller moved up into the Biggarsberg and occupied Dundee. On May 12 Roberts entered Kroonstad and on May 31 occupied Johannesburg, the Orange Free State having been annexed three days earlier. On May 30 President Kruger had fled with the state archives to Waterval Boven on the Komatipoort line. The gold mines were now securely in the possession of the British, and on June 5 Roberts occupied Pretoria practically without resistance.

Diamond Hill .- The Boers still continued to wage guerrilla warfare with skill and fervour for two years. On June 8 Buller, who had made a long halt after the relief of Ladysmith and reorganized his army and its line of communication, forced his way over Alleman's Nek, and on the following day occupied Laing's Nek, the Natal gate to the Transvaal, while Roberts fought a widespread battle against Botha, De La Rey and J. C. G. Kemp at Diamond hill, 20 mi. E. of Pretoria. The object of this action was to push back the Boers from the neighbourhood of Pretoria, but no sooner was this done than the northwestern Transvaal became active, in spite of Hunter's and Baden-Powell's advance from Mafeking through this district. As the British line of operations now extended eastward from Pretoria, the advance of these Boers to the Magaliesberg threatened their rearward communications, and as Buller had moved far more slowly than the main army there was not as yet an alternative line through Natal. Most serious of all was the pressure between Bloemfontein and the Vaal, where the Free Staters, under De Wet and other commanders, had initiated the guerrilla war as soon as Botha and the Transvaalers retired over the Vaal and ceased to defend them by regular operations. Large forces had been left behind during the advance on Johannesburg for the protection of the railway and the conquered territory, and these had now to be reinforced. Hunter and L. Rundle successfully herded M. Prinsloo with 4,000 Free Staters into the Brandwater basin (July 29)-an achievement which was marred for the British by the escape of De Wet, who soon afterward raided the western Transvaal and again escaped between converging pursuers under Kitchener, Methuen, H. L. Smith-Dorrien, Ian Hamilton and Baden-Powell.

Flight of Kruger.-Before this Roberts had initiated a movement from Pretoria to sweep down to Komatipoort on the Portuguese frontier, in which Buller, advancing across country from the south, was to co-operate. On Sept. 25 Komatipoort was occupied by Roberts' troops. From October British operations were confined to attempts to reduce guerrilla commandos which had taken the field. Kruger left for Europe in a Dutch man-of-war from Lourenço Marques and Buller returned to Britain. The Boer leaders definitely decided upon a guerrilla policy, deliberately dispersed their field army and then swelled and multiplied the innumerable local commandos. On Oct. 25 the ceremony of annexing the Transvaal was performed at Pretoria.

Kitchener Takes Command.—The prevailing opinion was that the war was over, and Roberts left South Africa, handing over the command to Lord Kitchener. Then followed a long pejod of British groping for a means to cope with the development of guerrilla tactics, which for the next six months were at their zenith. The railway communications were constantly damaged, isolated posts and convoys were captured, and the raiders always seemed able to avoid contact with the columns sent in pursuit. De Wet, after escaping from Brandwater basin, was hunted northwestward and crossed into the Transvaal, where, joining the local guerrilla bands, he surrounded an infantry brigade at Frederikstad. But, unable to reduce it, and threatened on all sides, he turned back. On Nov. 6 he was severely handled and his guns and wagons captured at Bothaville. But this misadventure only stimulated him. His emissaries roused the Free Staters west of Bloemfontein, and disaffection broke out in Cape colony to an alarming degree, while, as forerunners of the promised invasion, scattered bodies of Free Staters crossed the Orange river to swell the rebellion. From Bothaville De Wet made for Thaba Nchu, where the Bloemfontein garrison held a cordon of posts. He passed through this and on to Bethulie, capturing Dewetsdorp and 500 men en route. Pursued closely and finding the rivers in flood De Wet hid some of his men under Kritzinger near the Orange and himself doubled back, traversing again the line of posts east of Bloemfontein. Kritzinger, J. B. M. Hertzog and bodies of Cape rebels raided Cape colony as soon as they were able to cross the Orange, and Hertzog penetrated so far that he exchanged shots on the Atlantic coast with a British warship. All that the British forces could do was to localize the raids and to prevent the spread of rebellion. Botha meanwhile held his own in the northern Transvaal, attacked the railway posts on the Middelburg railway and captured Helvetia. De La Rey operated successfully and scathelessly in the western Transvaal, in concert with C. F. Beyers. Kitchener called for more men, and on Dec. 22 the war office announced that 30,000 more mounted men would be dispatched to the seat of war.

Concentration Policy .- With the opening of 1901 Kitchener tried new schemes. He withdrew all his detached garrisons except in the most important centres and set himself to make his railway communications secure. He determined to make the area of operations a waste, and instituted the concentration camps, into which he intended to bring the whole of the noncombatant inhabitants of the two republics.

Although the British sustained no great disasters, the new policy was not prolific in success. The Boers invariably dispersed before superior forces, and the removal of the women and children from the farms to the concentration camps, where the death rate from disease was appallingly high for a time, did not discourage the Boers from continuing the struggle.

On Feb. 10 De Wet, with five guns and 3,000 men, carried out his promised invasion of Cape colony. Passing the Bloemfontein-Thaba Nchu cordon a third time, he crossed the Orange to join Hertzog and rouse the Cape Dutch. But this invasion failed. By judicious use of the railway Kitchener concentrated sufficient troops in the colony to cope with the attempt, and, after being hunted for 18 days, De Wet escaped into the Orange River colony with the loss of all his guns, munitions and half his force. In the northern Transvaal a force under Sir Bindon Blood cleared the country, but could not prevent B. Viljoen from escaping eastward to join Botha. Botha's activity in the southeast caused Kitchener to dispatch thither a large force under French. This swept the country up to the Swaziland border, but Botha escaped. On March 3, after various raids, De La Rey, the lion of the western Transvaal, essayed an attack upon Lichtenburg, in which he was heavily repulsed. Signs of weakness were now apparent, and as a result Botha, acting with the authority of Schalk Burger, the representative of President Kruger, opened negotiations with Kitchener. A meeting took place at Middelburg, Transvaal, on Feb. 28. These negotiations, however, broke down mainly over the treatment to be awarded to Cape rebels.

Blockhouse Policy.-Kitchener now resolved upon chains of blockhouses like those protecting the railways. In April H. C. O. Plumer occupied Pietersburg, the last remaining seat of government open to the Boers. In July Botha applied for permission to communicate with Kruger. This was allowed, but Kruger advised

a continuance of the struggle. In the meantime, the concentration camps were becoming filled to overflowing, and a steady stream of captures was reducing the Boer resistance.

In August a proclamation was promulgated formally threatening the Boer leaders who did not surrender with permanent banishment from South Africa, but this proclamation had very little effect. Desultory fighting continued till the close of the year. Disaffection again became pronounced in Cape colony, and on Oct. 8 the whole colony was placed under martial law. The British began a succession of night marches and raids which practically blotted out the resistance in the eastern Transvaal. The year closed on a low note for the British, however, as De Wet on Christmas Eve captured a large force of veomanry at Tweefontein.

The "Drives."-In 1902 the blockhouse system was finished. But the Boers still had about 25,000 men in the field. The mobile columns, of which there were more than 60 in the field, could be pushed out along whatever blockhouse line they touched. In January, Viljoen was captured in the Lydenburg district. Early in February Lord Kitchener commenced his first drive, and it was so successful that it was evident that the key to the situation had been found. First the country east of the line Bloemfontein-Vereeniging was swept four times over, then the method was employed in the Transvaal, east and west, and finally against the Cape rebels. These British drives wore down the Boers' capacity resist. In April their executives met Kitchener and Alfred (later Viscount) Milner at Pretoria and agreed to convene a meeting of commando delegates to consider peace. The delegates met at Vereeniging on May 15 and deputed Botha, De Wet, De La Rey, Hertzog and I C. Smuts to negotiate for "limited independence." In Pretoria Kitchener and Milner rejected any such basis but, after Kitchener had had a private discussion with Smuts, terms were drawn up and telegraphed to the British government, which approved them with amendments. After long debates the Vereeniging assembly accepted them on May 31 by 54 votes to 6 and the same evening the Boer executives signed them in Pretoria.

Peace of Vereeniging.-The essential points of the peace were: (1) Surrender of all burghers in the field, with all arms and munitions of war; (2) all burghers duly declaring themselves subjects of King Edward VII to be repatriated; (3) no burghers who should surrender to be deprived of either their liberty or property; (4) no proceedings to be taken against burghers for any legitimate acts of war during the period of hostilities; (5) the Dutch language to be taught in public schools on the request of parents and to be allowed in courts of law; (6) rifles to be allowed upon the taking out of licences; (7) the military administration to be superseded by civil administration as soon as possible, the civil administration to lead up to self-government; (8) the question of the native franchise not to be decided until after the introduction of self-government; (9) landed property not to be subjected to any special tax to defray the cost of the war; (10) commissions to be formed to facilitate the repatriation of the burghers, a grant of £3,000,000 being given as compensation for the destruction of farms

In the whole war the British lost 5,774 killed and 22,829 wounded, while the Boers lost about 4,000 killed. At the end of the war there were 32,000 Boers in prison camps and 110,000 in the concentration camps. (L. J.; C. F. A.; X.)

SOUTHALL, a municipal borough in Middlesex, Eng., 10 mi. W. of central London by road. Pop. (1951) 55,900. Area 4 sq.mi. Flint weapons and the skeleton of a mammoth have been found there. In 830 the manor of Norwood was bequeathed by Warberdun to the archbishop of Canterbury. The manor house (1581) is preserved in the form of municipal offices. The urban district of Southall-Norwood was incorporated in 1936, and the borough returns one member to parliament. The chief industries are the manufacture of food products, motor vehicles and chemicals, building, engineering, a foundry and many light industries.

SOUTH AMBOY, a city of New Jersey, U.S., on the Raritan river connected with Perth Amboy by the Victory bridge (1926) and the Thomas A. Edison Memorial bridge (1940). Pop. (1950) 8,422; (1940) 7,802. South Amboy has various industries; it was laid out in 1835, becoming a city in 1908.

SOUTH AMERICA, the southern of the two American continents of the western hemisphere, situated between 34° and 82° W. long. and 13° N. and 55° S. lat. It is roughly triangular in shape and in the northwest is joined to the continent of North America (q.v.) by the Isthmus of Panama. South America is the fourth largest of the continents, having an approximate area of 6.856 975 sq mi. or about 12% of the land surface of the globe. Its estimated population in 1952 was 112,310,000, or 16.4 per square mile. South America lies much farther east in the Atlantic ocean than North America, the meridional line of New York city cutting it so as to leave 95% of the southern continent lying closer to the old world. See also AMERICA.

#### PHYSICAL ASPECTS

The Coasts.-The South American continent rises abruptly from the ocean floor along much of its coast, but the steepness of the continental margin is more marked on the western side than on the eastern. The west coast between 5° and 35° S. lat. displays little development of a continental shelf and drops off sharply to a series of deep submarine trenches parallel to the shore. In the neighbourhood of 26° S. lat. the Richards Deep exceeds 25,000 ft. in depth within 50 mi. of the coast. In general the Pacific coast follows the direction of the Andes. The whole west coast north of the Patagonian archipelago is but little articulated and is completely lacking in good natural harbours. The harbours of Guayaquil and Buenaventura would be exceptions to this rule if it were not that the rivers which empty into them carry so much silt that only constant dredging or carefully engineered dikes to direct the flow and deposit of the silt make them possible for steamers of deep draught.

From 41° S. lat. to Cape Horn the coastal zone is a series of islands, channels and fiords, results of subsidence and glaciation. In the far south glaciation is active at low elevations even today, glaciers coming down to sea level at the heads of the larger fiords and along the coast of Beagle channel.

North of 41° S. lat. the land between the Andes and the sea averages 40-50 mi. in width. Its character varies greatly. southern and central Chile a longitudinal interior valley is bordered on the west by a coast range whose elevation increases toward the north. Northern Chile has a high cliff coast situated in front of a series of interior basins. In Peru the coast range is largely absent. The entire strip from 30° S. lat. to the mouth of the Guayas river is arid, broken by a succession of transverse stream channels, most of them of intermittent flow. North of the mouth of the Guayas river the coastal belt is covered with tropical vegetation.

The east coast is in strong contrast with the west. Between Cape São Roque and Rio Grande do Sul the coast generally follows the sinuous eastern edge of the Brazilian plateau. Along this coast lie some of the world's most beautiful harbours, notably those of Recife, Salvador, Vitória, Rio de Janeiro and Florianópolis. Farther south the estuary of the Rio de la Plata is the most marked indentation of the whole South American coast. It is the outlet for the combined waters of the Paraná and Uruguay river systems. The Patagonian coast is but poorly endowed with natural harbours. Although many embayments occur, their utility is reduced by shallow water, high tidal ranges and coastal cliffs.

The east coast of South America has few islands, and these, except Trinidad, off the coast of Venezuela, and Marajó, at the mouth of the Amazon, are mostly small. Trinidad (area 1,864 sq.mi.) is separated from the continent by the Gulf of Paria. Along its northern edge is a range of mountains with a maximum height of 3,085 ft. which is geologically a continuation of the Cumaná range of Venezuela. On the south side of this island is the famous asphalt lake-the largest-known deposit of its kind. West and north of Trinidad and lying farther off the coast are several small islands of historical interest and considerable commercial importance: Tobago, Margarita, La Tortuga and the Curação group. The main island of the Fernando de Noronha group of volcanic islands, 230 mi. off Cape São Roque, has an area of only seven square miles. Although separated from the mainland by a channel 13,000 ft. deep, it really stands upon the submerged corner

of the continent. The Falkland Islands in lat. 51° S. also stand upon the submerged edge of the continent. Their fauna and flora indicate that they were once a part of the mainland from which they are now separated by shallow water. On the west coast north of the Patagonian archipelago are the Juan Fernández Islands west of Valparaiso, the famous guano islands close to the mainland of Peru, the Galápagos Islands on the equator and the islands of the delta of the Guavas river near Guavaguil

Land Relief .- The continent of South America is composed of the following major surface forms: the cordilleras of the Andes in the west and north, the Guiana, Brazilian and Patagonian uplands in the east and south; and the lowlands which divide the highlands from one another, namely, from north to south, the Orinoco depression, the Amazon basin, the Paraguay basin and the Pampa.

The Andes, one of the greatest mountain systems in the world. are more than 5,000 mi. long and are exceeded in average height only by the Himalaya. The southern Andes are a single chain, but north of 28° 5. lat. they form a complex system. Widening to a broad plateau in Bolivia, they narrow to a series of parallel ranges en echelon in Peru, continue in two parallel ranges in Ecuador and then fan out in Colombia into three distinct ranges, two of which end near the Caribbean shore while the easternmost continues through northern Venezuela into Trinidad. Volcanic cones are present in three separate areas. Drainage features are fairly complex. (For further details see ANDES.)

The Guiana highlands and the Brazilian shield together represent the ancient core area of the South American continent, divided into two unequal sections by the Amazon geosyncline. The crystalline rocks comprising the basement complex are granites, gneisses, schists and quartzites, overlain in some areas by old sandstones. Waterfalls and rapids occur along all the streams passing over the edge of these uplands. Angel fall in the Guiana highlands is the highest uninterrupted waterfall in the world (nearly 3,000 ft.). Paulo Afonso falls on the São Francisco rives in northeastern Brazil were being harnessed in the 1950s for a major hydroelectric installation. The crystalline rocks in areas of high rainfall weather into characteristic domelike shapes, as exemplified by the celebrated Sugar Loaf overlooking the bay at Rio de Janeiro. The highest point in the Guiana highlands is Mt. Roraima (elevation 9,219 ft.), and on the Brazilian shield, Pico da Bandeira (elevation 9,494 ft.). Patagonia is mostly a succession of arid plateaus, characterized by horizontal beds of sandstone and widespread lava caps.

In South America the development of lowlands is far greater in the interior of the continent than near the periphery. Only on the Atlantic coast, about the mouth of the Amazon and near the Río de la Plata, do extensive lowlands occur next to the sea. Typically, the lowland areas are pouch-shaped, with their greatest width inland. The Llanos del Orinoco occupy a structural depression between the northern Andes and the Guiana highlands. Orinoco river does not flow along the central axis of the Llanos but at the base of the Guiana highlands, in part a consequence of the great deposition of alluvium by tributary streams issuing from the rapidly eroding Andes. The Amazon basin has an exceedingly low gradient, Manáus, 800 air miles from the Atlantic, being only 150 ft. above sea level, and Iquitos, 1,700 air miles inland, only 350 ft. In spite of this low gradient, far less of the Amazon lowland is subject to inundation than is commonly supposed, the great bulk of the land lying above the level of highest flood water on the major streams. In its widest section the upper Amazon basin affords access over low divides (about 1,000 ft. elevation) into the Orinoco depression to the north and the Paraguay basin to the south. The Paraguay-Paraná geosyncline begins in the north with the great region of swamp (Pantanais grandes) in western Mato Grosso and with the Gran Chaco of Bolivia, Paraguay and Argentina. Slopes are so gentle that drainage is slow and imperfect. Toward the south the Chaco grades into the Pampa, while the swamps of Mato Grosso find their general counterpart in Argentine Mesopotamia. In depth and fertility the soils of the Pampa are among the best in the world.

Rivers and Lakes.—The most important river systems of

South America-the Amazon, Orinoco and the Paraná-La Plata s stem-have the greater part of their drainage basins in the lowland belt. The chief headwater tributaries of the Amazon and the Orinoco have their sources in the Andean highlands, where they have cut deep valleys The principal sources of the Paraná-La Plata system are in the Brazilian plateau, although the Pilcomayo and Bermejo (right bank tributaries of the Paraguay) rise in the Andes of southern Bolivia and northern Argentina. These three river systems together drain an area of about 3,700,000 sq.mi. During the rainy season all of them overflow their banks and flood large sections of the central lowland belt. The Amazon is the largest river in the world, though not the longest. At the narrows of Obidos, where it is constricted by spurs of highland projecting from north and south, it has a width of 14 mi., a depth of 270 ft. and an average current of 2.7 m.p.h. During flood stages it rises about 25 ft. and the current in the narrows increases to 4.2 m.p.h.. The main stream is navigable for ocean steamers as far as Iquitos, while many of its tributaries are navigable for steam launches almost to the foot of the Andes. In time of high water the main stream of the Orinoco is navigable for 1,000 mi or more.

Other important rivers are the Magdalena in Colombia, the Essequibo in British Guiana and the São Francisco in Brazil. The Magdalena is navigable, in two sections separated by the rapids at Honda, for river steamers as far as Girardot, the river port of Bogotá. The São Francisco, which rises in the highlands of Minas Gerais, is navigable nearly to the falls of Paulo Afonso, 140 mi. from its mouth, and for 850 mi. above the falls.

Most of the lakes of South America are mountain lakes in the Andes or along their base. Of the Andean lakes, Titicaca and Poopó are the largest. (See Andrs.) The glacial lakes along the eastern base of the Andes in southern Argentina and those of the Lianquinue district of southern Chile are described in the articles on the Andes, Argentina, Chile and Patagonia. There are many lakes scattered over the flood plains of the great rivers, but these are mostly phase of river development. Along the east coast there are occasional lakes, such as the Lagôa dos Patos of southern Brazil, of brackish water, produced by depression of the coast and the closing of the mouths of estuaries formed thereby or by barrier beaches thrown up by the sea. Lake Maracaibo is a large, narrow-necked bay, somewhat like that of Rio de Janeiro, rather than a true lake. Its waters, however, are brackish. (H. J. Bn.)

## GEOLOGY

The most extensive old land areas (Pre-Cambrian) of South America are found in the plateaus of Guiana and Brazil, where the ancient crystalline granites and gneisses have been laid bare over large areas. The Brasilides, so-called, are a series of Pre-Cambrian and pre-Devonian folds of which traces are found on the western border of the Brazilian plateau and as far south as the Sierras in the Argentine provinces of Córdoba and La Rioja. These old land areas formed the larger units in a chain of islands of which the old rocks of the Falkland Islands are a part. On their shores were laid down the sedimentary beds of the Cambrian seas. At the close of the Cambrian period these Pre-Cambrian islands with their Cambrian sediments were uplifted, and many united to form continental masses of considerable extent. During the Silurian period, however, seas still covered a large area including the present basin of the Paraguay river and a large part of the present basin of the São Francisco and extending northward between the axis of the Andes and the Mato Grosso highlands and eastward by way of the region now occupied by the lower Amazon valley.

During the Devonian period further uplift and the consequent disappearance of the Silurian seas from the basin of the São Francisco increased the area of the continental mass; but in early Carboniferous times the sea still covered a narrow strip through the lower part of the Amazon valley and part of what is now the Andes south of the equator. During the Permian the basin of the Paraguay and the southeast coast of Brazil were covered with lagoons and swamps in which here and there coal beds were laid down.

Continental Permian deposits have been found at a number of

places in the southern part of the Brazilian plateau, in northern Argentina and in the Falkland Islands. Analogies between Permian fauna and flora of South America and South Africa are accepted as evidence of a Permian continental mass, known as Gondwana, connecting South America with South Africa and India, the western limits of which are formed by the Argentine precordillera between San Juan and Jachal where the Permian layers are strongly folded. These folded Permian layers are continued southeastward by the sierras of the Argentine province of Buenos Aires and are known to geologists as Gondwanides. South of them, between the Negro and Chubut rivers, is the Patagonian massif, which consists, like the Brasilides, of very old rocks and may have been connected with an ancient antarctic continent. Against this massif and between it and the Andes, and antedating the latter. is a series of Cretaceous folds known as Patagonides. At the close of the Devonian there was widespread volcanic activity that covered with lavas large areas in what is now Paraguay and Brazil.

The importance of Jurassic and Ctetaceous marine deposits in the Andes is evidence that, during the Mesozoic period, the region now occupied by the Andes was a great geosyncline occupied by the sea between two continental masses, one of which has since subsided to form the Pacific ocean. This geosyncline connected at the north end with a sea that reached from the region of the present West Indies to the present Mediterranean and persisted through the Mesozoic and into the early part of the Tertiary. The South America-South Africa land mass (Gondwana) continued from the Carboniferous to the Cretaceous and may have persisted into the Tertiary.

There is no evidence on the present coast of Brazil of invasion by the sea between the Devonian and the Cretaceous, while the first invasion of the east coast of Patagonia and, consequently, the formation of the South Atlantic ocean dates from the Upper Cretaceous. The folding of the Andes also began in the Upper Cretaceous and continued into the Tertiary, although how far into the Tertiary is not known.

Great changes took place in the Tertiary period. The continent rose considerably higher than its present elevation, and the continental land mass was, consequently, much larger than at present, including such coastal islands as the Abrolhos Islands on the east coast of Brazil and the Falklands. It is possible, also, that, during this period, South America had land connection with New Zealand and Australia by way of the antarctic continent or through the South Pacific ocean. The formation of the Isthmus of Panamá with the resulting migration of North American faunal species to South America also dates from the Tertiary period; but its formation could not have taken place until the Pliocene, since the analogies between the marine fauna beds of Navidad (Chile). which date to the end of the Miocene, and European fauna of the same date can be explained only by the existence of free communication between Europe and the west coast of South America by way of the Tertiary Mediterranean up to the end of the Miocene. The elevation of the Andes during the Tertiary period was attributable in part to the elevation of the continent as a whole. It was in large part assisted by the folding of the rocks and the outpouring of lavas and the accumulation of other volcanic materials in the neighbourhood of the vents. Nor was this volcanic activity confined to the Andean region. It extended into Venezuela and the islands along the north coast, the Patagonian plains, the highlands of the Paraná basin and as far east as the islands of Fernando de Noronha. Toward the end of the Tertiary period subsidence again occurred and the sea entered the Amazon, Orinoco, Cauca and Magdalena valleys and the Maracaibo basin and again made an island or groups of islands of the Guiana highlands. In recent times volcanic activity has greatly diminished over the continent and has ceased entirely in its eastern and northeastern section.

Throughout the southern part of the continent there is evidence of several periods of glacial development and recession during the Ice Age. Ice covered the whole of the Patagonian plateau as well as the western side of the Andes but the continental glaciation did not extend as far north on the east side of the Andes as on the west. Throughout the Andean zone there is evidence that the

present glaciers are remnants of larger glaciers. There were no glaciers in the eastern or Brazilian section of the continent. (X)

#### CLIMATE

South America, the only southern continent to extend far into temperate latitudes tapers toward the pole, and hence does not experience the extremes of temperature of the northern continents. The winters in temperate latitudes are warmer and the summers cooler than in North America or Asia. The continent is broadest in the equatorial section and has larger areas of hot tropical low-lands and cool tropical uplands than any other continent.

Average annual temperatures in the Amazon basin are about 80° F., and seasonal variations are slight. Quito, near the equator but at an elevation of 9,350 ft., averages about 55° F. in every month. Seasonal temperature ranges increase with latitude and reach their maximum in northwestern Patagonia, where July averages 32° F. colder than January. Winter freezing at low elevations is common in Tierra del Fuego and Patagonia, is by no means rare on the Argentine Pampa or in southern middle Chile, and occurs in southern Brazil at elevations above 1,000-2,000 ft.

The northward-flowing Humboldt (Peru) current and associated upwelling water keep west-coast temperatures cool as far north as the equator. The coast of Argentina is cooled by the Faikland current. Elsewhere around the continent warm water washes the shores: the South Atlantic equatorial current flowing west encounters the bulge of Brazil and divides into the south-flowing Brazil current and a coastal current which flows northwest into the Caribbean; on the northern Pacific coast the equatorial countercurrent sends a warm-water eddy to wash the shores of western Colombia and Ecuador.

The rainfall pattern of the continent is closely connected with the distribution of winds and air masses. Most of tropical South America east of the Andes has prevailing winds from the northeast, east or southeast. These transport moisture from the warm Atlantic ocean and give copious rainfall by convection. Rainfall totals average 90-120 in. a year along the lower Amazon and the coast of the Guianas. The middle Amazon basin has somewhat less rain (60-70 in.), and the upper basin has more than 90 in., possibly exceeding 150 m. in exposed portions of the Andean foothills. The interior of the Brazilian bulge is generally dry and periodically subject to extreme drought. The Llanos del Orinoco and the Guiana highlands have moderate to high rainfall with a strong maximum in summer. Much of northwestern South America has two rainfall maxima associated with the two periods of high sun. The Pacific shores of Colombia and northern Ecuador are extremely rainy, while the Gulf of Guayaquil marks the transition to the dry west-coast conditions of Peru and northern Chile. The Atacama desert is one of the driest areas in the world. South of 33° S. rainfall is adequate west of the Andes, and south of 38° S. it becomes excessive. Cyclonic precipitation is characteristic of middle and southern Chile, associated with the westward movement of storms from the Pacific. Valdivia (lat. 40° S.) averages 105 in. of rain a year, and the fiorded coast farther south receives even more. Argentine Patagonia lies in the rain shadow of the Andes and is mostly steppe and desert. The grasslands of Argentina, Uruguay and southern Brazil have moderate rainfall (25-50 in.) well distributed throughout the year. Eastern Paraguay is moist (50-75 in.), while the Chaco is moderate to dry in rainfall and has a dry winter. (H. I. Bn.)

#### SETTLEMENT

Discovery.—The continent of South America was first visited by Europeans in 1498 when Columbus, on his third voyage, touched near the mouth of the Orinoco. Others soon came after and by 1509 the east coast had been followed as far as the Rio de la Plata. In 1513 Balboa discovered the Pacific ocean at the Isthmus of Panamá; in 1520 Magellan navigated the strait that bears his name; in 1527 Pizarro landed on the coast of Peru at Tumbez, and, in the same year, Cabot ascended the Plata and Paraná rivers as far as the mouth of the Bermejo; in 1533 Cartagena was founded and the native town of Quito peacefully occupied; in 1535 Pizarro founded Lima, and, in the same year Almagro

invaded Chile and Mendoza established a settlement at Buenos. Aires; in 1537 Jiménez de Quesada made his way from Santa Marta up the Magdalena river to Bogotá, the capital of the Chibchas; and in 1541 Valdwua founded Santiago de Chile and Orellana travelled from eastern Ecuador to the Atlantic by the Napo and Amazon rivers. It is claimed that the bay of Ro de Janeiro was discovered by the Portuguese in 1502. Afonso de Sousa visited it in 1531 but went on to São Vicente near Santos

Aboriginal Inhabitants.-In contrast with North America. which had few Indians, South America was peopled by several million aborigines. In the northern mountains were the Chibchas. and along the northern coasts were the Caribs and Arawaks, the latter extending southward. In Brazil and the upper Plata basin the Tupi-Guarani tribes predominated, with a semisedentary culture. The extreme south was sparsely populated by the barbarous Patagonians on the east and the warlike but disciplined Araucanians on the west. Far more numerous than all these tribes taken together, and more advanced in civilization, were the lowland Quichua and highland Aymara Indians who populated the Inca empire, stretching from southern Colombia to central Chile. They were ruled by the small, aristocratic Inca race in a complex paternalistic civilization based on enforced communal labour. They practised crop rotation, maintained highways and bridges, used stone in construction, worked the nonferrous metals and produced excellent pottery and textiles. Even among the Inca peoples, however, there was no form of writing, no wheel or saw, no keystone arch and no working of iron, and elsewhere in South America the Indian cultures were still more rudimentary. There were no domestic animals except for llamas in the high Andes. The dwellings were most commonly of adobe, although tile were not unknown, or in the tropical regions primitive palm huts. The food crops were maize, manioc, potatoes, millet (quinoa), beans and peppers, and the principal fruits were bananas and mangoes. The beverages were cacao and various brewed liquors.

Colonial Settlement, West Coast.—The initial penetration of the Spaniards was into the Inca region. Its primary purpose was to secure precious metals, and after seizing what the Indians possessed the conquerors turned promptly to the mining of additional supplies. Agriculture was necessary, however, to provide food and clothing; and in searching for gold and silver many places were occupied which were suited only for nonmining pursuits. The Spanish monarchs were zealous churchmen, too, and sought from the outset, through priests sent with the expeditions, both to convert and to improve the natives. Thus many settlements were based on farming, and all kinds of European domestic animals were introduced and propagated with diligence.

The principal mining regions were in the high Andes inland from Lima and in south central Bolivia. While gold extraction was widely scattered, with Colombia eventually leading, silver was far more plentiful; and the discovery of the huge "silver mountain" at Potosi in 1545 made that place for many years the largest population centre in the hemisphere. The principal farming areas were atong the Peruvian coast, where sugar, rice and maize were grown on a large scale, and in the "Central vale" of Chile, which was for a time the granary of Spanish South America.

Both mining and agriculture were based on the labour of the Indians, who had already been accustomed by their Inca masters to systematic toil. They were adapted without very great difficulty to Spain's encomienda system, under the direction of the mine owners and plantation operators who received grants from the Spanish crown. By the end of the 16th century, when the process of subjugation had been in good part accomplished, the Andean countries were organized in a wide system of agricultural and mining settlements. The number of Spaniards needed for troops and administration, as well as for mining, farming, industries, construction, roads and trade, was large, and these men at once formed irregular unions with the Indian women, since relatively few families came from Spain. The hybrid or mestizo populations which resulted from this intermingling soon swelled to large proportions, particularly in the lowlands; and the mestizos played an important auxiliary role as overseers and superior employees in all activities.

· As a basis for settlement the mining operations receded somethat in the 17th century, since the best deposits became partially exhausted, and other occupations increased. In the highlands the Merino sheep gave the Indians a large new industry. In Chile, Peru and western Argentina wine grapes and olives were grown. In Ecuador vegetable ivory, balsa wood and after 1700 cinchona were exploited. The numerous edifices and houses of European type were built of brick as well as stone or adobe, with the necessary wood brought from southern Chile. Boatbuilding was active.

Colonial Settlement, East Coast .-- Unlike the Andean west coast countries, the eastern regions of the continent had rather few Indians and for two centuries were not known to contain minerals. Settlement from the beginning was based upon agriculture and natural products. The Spanish occupation in the Plata basin was retarded by the southern Indians, with whom the Spaniards were at first unable to cope. They found in Paraguay, however, a well-watered rolling country peopled by the nonnomadic and nonhostile Guaranis, and Asunción in 1537 became the seat of Spanish operations. From it were founded towns farther down the river and eventually in 1580 the city of Buenos Aires. By the late 18th century the rich humus of east central Argentina was coming into use for grains, and the plains for cattle; while in the north and in Paraguay tropical crops and verba maté were produced. The absence of metals and inorganic combustibles handicapped other development, as did the Spanish prohibition of any trade except with Spain via Peru.

The settlement of Brazil, almost one-half of the continent, was undertaken through 20 captaincies granted to nobles for tropical plantations. Because the Indians were found to be ineffective workers, Negroes were imported in large numbers from Africa. Thus along the northern littoral, despite uneven management and deficient rainfall, the production of sugar, rice, tobacco, indigo and cacao soon became extensive; and dyewoods, cabinet woods and animal skins were also exported. Southward from Rio de Janeiro, and particularly in the cooler tablelands of São Paulo, a more European type of farming came into existence. The hardy pioneer population showed energy in subduing and utilizing the Indians, who were satisfactory workers, thus opening the interior of central Brazil. At the beginning of the 18th century came the discovery of gold, diamonds and a diversity of valuable ores in Minas Gerais, attracting an influx of population and making Brazil the world's main producer of gold for more than 100 years. In the south the settlement was more gradual, but came to be based on cattle and sheep.

Some Indian admixture was acquired by the gaucho herders in southern Argentina, while in Paraguay, southern Brazil and northeastern Argentina there were many unions with the Guaranis. In northern Brazil the preponderating Negro majority interbred freely with both Indians and whites, but segments of the Europeans, which included Dutch and French, kept their homogeneity.

Post-independence Development.-With the independence of the Spanish colonies in the early 19th century the last Spanish restrictions upon trade and local enterprise were swept away. Freedom to export to world markets aided the expansion of agriculture, even though factional strife hampered productivity. Road construction progressed, and after 1850 railways were built from many coastal points into the interior, usually with British and other external assistance. Wheat and hides from Argentina were sold in quantity to Europe. Coffee was introduced into São Paulo, and within a few decades gained for Brazil the pre-eminence in that staple which it thereafter maintained. Cacao became important in Ecuador, Brazil and Venezuela.

Immigration was actively promoted and reached considerable volume in the Atlantic countries. Agriculture on the west coast showed less expansion, because of remoteness and the exiguity of arable land, while mineral industries for a time flagged. In no part of South America did independence bring the breaking up of the vast landed estates, and agriculture in consequence did not have the stimulus of diffused ownership. A compensatory gain in Peru was the exploitation of guano on the Chincha Islands, and in Chile the export of natural nitrate from the Atacama desert. The arrival of manufactures from Europe at lower costs than in

colonial days was not favourable to South American industrial development, especially as motive power, industrial training and local capital were not available. Yet simple industries became widespread: textile mills multiplied greatly, cereals, sugar and leather were processed, and the output of clothing, furniture, footwear, soap, ceramics and beverages was everywhere augmented.

The decades just before World War I brought new developments. Natural rubber was exploited in the Amazon, but exports of nuts, waxes and skins proved more permanent. The Plata region built large packing plants and shipped chilled meat, while quebracho extract was produced in the Paraguay area. Along the Caribbean bananas were cultivated, and the mountain valleys of Colombia developed mild coffees. Chilean nitrate became a bonanza, and Chile began to utilize its coal and iron. Copper and tin mining were revived in the Andes, and manganese from Brazil and bauxite from Guiana entered world trade.

20th-Century Development .- The opening of the Panama canal benefited the west coast, and World War I gave added importance to South American metals. Both tended to shift trade away from Europe to the United States. After the war petroleum extraction was begun in Colombia and Venezuela; and postwar scarcity of manufactures, coupled with mounting nationalistic sentiment, stimulated factory projects for "national" goods. Governments secured large loans from New York city and London and improved roads, harbours and education. Both immigration and the birth rate rose. The universities and press participated in the modernization movement. The world depression of the 1930s reversed these trends as to metal exports and immigrant imports, although a number of Spanish republican refugees arrived with skills and capital. But popular discontent arising from the depression caused agrarian reform to be undertaken in several countries, to the ultimate advantage of agriculture.

World War II resuscitated all exports from South America, despite the German submarine campaign, and strengthened the continent's over-all financial position. Postwar exports levelled off at better than prewar volume, and the continent could afford large purchases of equipment. Many countries created official development corporations to promote hydroelectric power, new lumbering and metallurgical activities and general industrialization; and the indexes of industrial production showed gains of 50% or more as compared with the interbellum decades. There was a striking increase in the petroleum output of Venezuela, and that nation's vast iron ore deposits were opened up. Agriculture and sanitation were improved, with technical co-operation from the U.S. and U.N. Fisheries were expanded especially in Peru, and the crushing of vegetable oils was increased.

Commerce and Population .- The exports of South America by the 1950s were valued at approximately \$5,500,000,000 annually, with Argentina accounting for some 30%, Brazil 25% and Venezuela 22%. In typical post-World War II years, half of Argentina's exports consisted of grains and flaxseed, but meat, hides and wool shipments were large. Brazil furnished more than half the world's coffee and had some importance in cotton and cacao; Venezuela was the third largest mineral oil producer; and Colombia sold one-sixth of the world's coffee. Chile continued to ship mainly copper and nitrate; and Peru, although its minerals were substantial, was primarily a source of cotton and sugar. Uruguay exported wool, meat and hides. No other country had exports valued at more than \$100,000,000 annually, but Bolivia's exports of tin were large and significant. Nontropical food exports went mainly to Europe. For tropical foods, coffee and minerals the United States was the leading destination, with Europe, including England, a fairly close second. Exports among themselves by the republics were not large, except in the case of Peru's outward trade.

During World Wars I and II there was a shortage of merchant tonnage available for South America, and several republics consequently undertook governmental ownership and operation of shipping. Argentina by 1950 had 1,000,000 registered tons and Brazil 700,000 tons, while Chile, Venezuela and Peru also possessed respectable fleets. Coastal traffic was reserved to national vessels: but of the maritime traffic as a whole the major part was still borne by foreign ships, with the United States' share considerably increased since World War II. River traffic remained extensive on the Paraná-Paraguay river system and the Magdalena but relatively slight on the Amazon, which showed little development.

Railway construction, largely completed by 1914, was greatest in the countries having extensive interiors. Argentine railways by the 1950s had 27,000 mi. and Brazilian railways 21,000 mi., while Chile, Peru, Colombia and Uruguay each had 2,000 mi. or more. Argentina, Uruguay and Chile had fully integrated broad-gauge networks, and good progress in integration had been made in Brazil and Peru; but there remained many unconnected railways of diverse gauges. Many governments had taken over the ownership, and often the operation, of the railways from the original British and other foreign entrepreneurs. The railway freight traffic of the continent in 1950 was 25,600,000,000 ton-km., more than twice that of Australia but only five-sevenths that of Africa. Highway construction and improvement had increased rapidly, and Brazil had 160,000 mi. of roads, Argentina 38,000, Chile and Uruguay 25,000 each, Peru 20,000, Bolivia 15,000 and Colombia 12,000. Many of these roads were far from modern, and highway transit between countries, while usually possible, remained slight. In aviation South America had a remarkable development after 1930, as topography renders this mode of transport necessary and economic. Brazil and Colombia led the way, because of their geographic problems, but Argentina, Chile, Peru and Venezuela all established active air lines. There was considerable foreign collaboration in air enterprises.

For the decade ended in 1950 the population growth in South America was at a rate higher than elsewhere in the world. Of the total of 109,000,000 persons in that year, Brazil had 52,000,000, Argentina 18,000,000, Colombia 12,000,000, Peru 8,000,000, Chile 6,000,000 and Venezuela 4,500,000. The aggregate net immigration since independence had been about 9,500,000 persons, of whom some four-fifths had entered Brazil and Argentina, divided about equally. In both countries Italians constituted the largest group, with Portuguese second in Brazil and Spaniards in Argentina. German immigration was substantial in the 19th century and continued thereafter on a small scale. By the 1950s there were 2,000,000 persons of German blood in Brazil, Argentina and Chile, principally in southern Brazil. Immigrants from the eastern Mediterranean and eastern Europe had been numerous and were active in trade. Post-World War II immigration was small, except that of Italians into the Plata region. The immigration had been entirely white, and the proportion of white blood throughout the continent had in other ways also increased. While the Indian and Negro populations in the Andes and north Brazil were not decreasing, their habitats remained limited; and unions between them and the whites had long been unusual. Among the mestizos and mulattoes there had been a steady tendency for natural selection to favour the lighter strains, and most mestizos continued to be regarded as Caucasians having a quantum of Indian blood. The interior regions of South America remained sparsely peopled, since water-power sites, transportation and skills are more available near the coasts. The urban rather than the rural populations had shown the increases, and this meant the rise of middle-class elements.

the increases, and this meant the rise of middle-class elements.

## ARCHAEOLOGY

Before their discovery by the Europeans in the 16th century, the inhabitants of the South American continent lacked any form of script and, unlike the Maya and Aztecs of Mexico and Middle America, also had no type of recorded calendar. Consequently,

knowledge of the prehistory of the continent is based on local traditions, accounts written by the first discoverers and especially of a rachaeological field excavations. Since traditions of any significance are generally lacking except for the Incas of Peru, and since historical accounts are limited to the conquest period, the dependence on archaeology is even greater. Although much work had been done by the 1950s, there were still many unexplored regions so that reconstruction of the past was incomplete and uneven.

The earliest inhabitants of South America were nomadic hunters, fishers and gatherers who pushed southward from North America by way of Middle America and the Isthmus of Panamá. There are, to be sure, other possible migration routes including the transpacific, but the evidence for these was yet to be satisfactorily established in the 1950s. Remains of the early nomads had been found in such widely separated areas as highland Ecuador, eastern Brazil and southern Chile near the Strait of Magellan. The remains included skulls, none particularly primitive, and stone and bone implements.

The hunting and gathering pattern survived in southern South America until historic times, but elsewhere the development of more advanced cultures and civilizations was based on farming. Various centres of plant domestication have been suggested, such as the marginal areas of the tropical forest, the high Andes, Middle America and even the old world for such plants as the bottle gourd, sweet potato and perhaps cotton. Wherever the origin, the highest civilizations in South America were based on intensive agriculture, and this was best developed in the Andean mountains and along the Pacific coast, particularly in the central Andes, which includes the mountains and coast of Peru and part of Bolivia.

The gross outline of cultural development in the central Andes has been reasonably well established. The earliest remains, found on the north coast of Peru, represent a population that depended heavily on fishing and gathering of shellfish for its subsistence, but that also cultivated some domesticated plants, including the bottle gourd, squash, beans, chill pepper and cotton. These people had no ceramics but did make baskets, mats, crudely flaked implements and cloth from twined cotton fibres. They lived in small, subterranean houses and cooked their food by placing hot stones in some kind of water containers. Their remains are roughly dated as from 3000 to 1000 B.C. (These dates, as well as others used in this account, are approximations based on the radioactive carbon, or carbon 14, dates published by W. F. Libby in 1952).

Ceramics were introduced at approximately 1000 B.C., together with true weaving and domesticated maize and manioc, which initiated a long formative period during which many new techniques were tried and perfected. Systems of irrigation were established, new metallurgical techniques were invented, and many different shapes of sun-baked clay adobes were tried out in buildings. Religion too grew in importance, particularly in the Chavin culture. The stylized Chavin feline design, the dominant religious symbol, appears on stone carving, textiles, ceramics and other mediums in many parts of the mountains and the coast.

The long formative period was the basis for the distinctive regional cultures which flourished in almost every part of the central Andes from approximately A.D. 400 to 1000. This has been called the Classic period because of the high artistic and technical achievements in ceramics, metallurgy, weaving and architecture Some of the outstanding local cultures are the Mochica (also called Early Chimu) on the north coast of Peru, noted for faithfully modelled and realistically painted ceramics; the Nazca on the south coast, famed for polychrome embroideries and multicoloured clay vessels; Recuay in the northern highlands, with incised statues and small modelled figures on ceramic vessels; and Tiahuanaco in the Bolivian highlands, noted for polished and fitted stone masonry and low-relief carving.

Each of the regional cultures started to expand as it grew stronger, and conflict followed. The Tiahuanaco culture became dominant and achieved the greatest extension. It can be traced throughout much of Bolivia, north Chile and the coast and highlands of Peru. There are indications that this Tiahuanaco expansionist movement was strongly motivated by religion, but it was none the less sufficiently organized to eclipse most of the local

styles which it encountered. Although roughly dated from AD 1000 to 1300, there is no evidence that any true unity, political or religious, was maintained throughout this time period, and as its influence diminished, regional cultures once again reappeared, each now definitely formulated into local political units. At least one of these, the Chimu on the north coast, was well enough organized to be called a kingdom. Its arts and crafts reflected the traditions of the earlier Mochica now mixed with Tiahuanaco. Its population was numerous and was settled in large ceremonial cities, such as Chan Chan, near the contemporary town of Trujillo, Peru, or assigned to live in strategically placed garrisons. The political and religious organization shows many parallels to the Inca empire which followed.

The Inca empire, discovered in full flower by the Spanish conquerors in 1532, was thus the culmination of many years of cultural growth. The Incas contributed their genius for political organization and built up an empire which not only united all the central Andes but also extended north to Colombia and south to Chile and Argentina. For the Inca period the archaeological evidence is supplemented by traditions and by the written accounts from the early conquest years.

Unfortunately the accounts preserved are not in agreement on all points, and it is not easy to reconcile discrepancies. For instance, one of the most important documents relating to Inca civilization is the account of Garcilaso de la Vega, son of a lady of the ruling Inca house by one of the conquerors, who had been brought up in his mother's family and had exceptional opportunities for collecting the ancient traditions. But his natural sympathies led him to stress the virtues of the Inca regime to the point of exaggeration. On the other hand, the "official" history of Pedro Sarmiento de Gamboa was written rather with the idea of showing the Incas as oppressors and the Spaniards as liberators.

In general terms, the history of the rise of the Incas to power would seem to be as follows: Their history begins with a frankly mythological account of a migration from the south to Cuzco, under the leadership of Manco Capac. For years the Incas, living the same life as other Andean tribes, consolidated their power in the Cuzco valley, and then began to make their influence felt among the surrounding tribes. A career of conquest, undertaken partly as a religious crusade, eventually raised the tribe to the position of a ruling caste, whose sovereign was regarded as a god on earth. The history of this dim period is discussed fully in Philip A. Mean's book (see Bibliograbhy).

The first historical Inca (bearing the royal title of Sapa Inca) was Sinchi Roca, by most authorities recorded as the "son" of Manco Capac but, in Fernando Montesinos' list, separated from him by a long series of tribal rulers. His date may be set at about A.D. 1200. The list of Inca rulers in historical times (concerning which the early chroniclers are not quite in agreement) seems to have been as follows:

- Sinchi Roca
   Lloque Yupanqui
   Mayta Capac
   Capac Yupanqui
   Inca Roca
   Yahuar Huacac
- 7. Viracocha8. Pachacutec9. Tupac Yupanqui
- 10. Huayna Capac 11. Huascar 12. Atahualpa (usurper)

According to Means's account, the Inca power began to make itself felt outside the Cuzco valley in a southerly direction (among the Colla peoples) and was consolidated by Sinchi Roca's successor. Mayta Capac continued the policy of expansion toward the south, and the activities of these rulers led to the annexation of a large region, extending as far as Lake Titicaca, in the reign of Capac Yupanqui. The next two reigns appear to have been devoted to the settlement of newly acquired territory, but in the time of Viracocha a crisis arose which decided the fate of the cultured peoples of South America. West and northwest of the Inca domain, the Chanca people, living under similar conditions, had built up a powerful confederation. A clash was inevitable, and the struggle was desperate; but the Inca, supported by their newly acquired tributaries from the Colla, emerged victorious. As a result, a large expanse of territory was added to the Inca sphere, inhabited by cognate peoples, practising similar customs and religious observ-

ances, and therefore amenable to the new conditions. The annexation of the Chanca district opened the way to the coast, the conquest of which, for climatic and religious reasons, was a long and laborious process. The reign of Pachacutec seems to have been devoted to a reorganization of the Inca system in view of its new colonial responsibilities. But under Tupac Yupanqui and Huayna Capac, the two great "conquerors" of the Inca dynasty, Inca domination was imposed throughout the highland region from Tucumán in Argentina to Quito in Ecuador. The conquest of the Ica and Chimu peoples of the coast was a more laborious process.

John H. Rowe's account in 1946 (see Bibliography) confirmed the general sequence of Inca conquest but reduced the time span. According to Rowe, the first seven Inca rulers were obscure war chiefs, and the conquests attributed to them were probably only local raids. It was under Pachacutec, the eighth Inca, that true expansion began in approximately 1438. In this view, the Inca empire was built up in less than 100 years, which may help account for its rapid collapse following the Spanish conquest in 1532.

Architecture.—Extensive and large-scale building for both public and religious purposes was characteristic of all periods in the central Andes. In general, buildings in the rainy highlands were of stone, while on the dry coast the common construction material was clay. The highland site of Chavín, attributed to the early formative period, has symmetrically arranged temple units, some with three interior floors of intricate galleries, rooms and vents. The inner construction is of split slabs and rubble fill, but the outer facing is of dressed stone slabs laid in rows, alternating thick and thin. Low-relief carving and sculptured heads on tenons serve as wall ornament.

The Tiahuanaco masonry in Bolivia is noted for its well-dressed and fitted sandstone and basalt pillars and blocks. The typical facing wall has uprights set at intervals, filled between with smaller blocks. Fitting includes notches, joints and grooves for copper cramps. Monolithic gateways with relief friezes are associated, and stone carved heads and figures are part of the architectural plan. The Incas in their extensive building at Cuzco used various types of masonry, depending on the purpose and function of the construction. The zigzag walls of the triple rampart of the fortress of Sacsahuaman are made of immense slabs, each dressed and ground at the site for fitting. Similar walls in Cuzco employ this same "polygonal" style but with smaller stones. Other walls are built of small, rectangularly dressed blocks. Some constructions, such as the city of Machu Picchu, not far from Cuzco, show combinations of walls of rough stone and those of carefully dressed slabs and blocks. The principles of systematic bonding and accurate fitting were inherited from the Incas' predecessors, and, to take a single example, the apsoidal end of the great temple to the sun at Cuzco (the Coricancha) is a famous masterpiece of the early architecture of the Incas.

Contemporary accounts indicate that the roofs, even of the most important buildings, were constructed of thatching supported by beams. Exterior ornamentation was limited in the main to the breaking of plain surfaces by series of niches, but many, perhaps most, of the surviving stone-built ruins of pre-Inca and Inca times achieve their effect simply by their quality of massiveness and the perfect fitting of the blocks which compose them. Both the quality and the quantity of the masonry representing all the periods in the highlands mark the inhabitants as master masons. Apart from actual buildings, there exist throughout the area literally hundreds of miles of stone terracing, built for agricultural purposes on the slopes of the Andean valleys.

On the rainless coast buildings were constructed in sun-baked clay (adobe). In this region are found enormous structures in the form of stepped pyramids (especially at Moche, in the Trujillo area), often supporting the remains of shrines. All served a funerary purpose, since the early population buried their dead in what was the local "churchyard." Polychrome fresco designs are found on some of the walls.

The art of clay architecture attained a very high level in the Chimu period, and the great ruins of Chan Chan, near Trujillo, include long series of walls ornamented with intricately modelled designs, based mainly on textile art. Later buildings on the coast reflect the Inca conquest The severity of Inca stonework is reproduced in the local material, sun-baked clay.

Worship and Burial.—Detailed accounts of the Inca religious beliefs and practices exist, but for earlier times there are no records. The ceramic designs and temple wall decorations show numerous anthropomorphic figures, indicating that birds, animals and even plants were important in the religious concepts. However, more specific interpretation is limited to the occasional references in the Inca traditions, which state that the Tiahuanaco people worshiped a supreme god, Viracocha, associated with rain and thunder, and that the late period coastal people revered the moon and the sea.

The whole of Peruvian religion, in Inca times, is connected with the word huaca, belonging to the Ouichua dialect spoken by the Inca and employed throughout their empire as the official tongue. There is no one word in English which can convey its meaning. It means "holy" in the fullest sense (and was applied to the highest and most mysterious gods). Tribal gods and clan gods were huaca, and the meaning of the word was extended to include objects which were regarded as uncanny or merely unusual, such as a queerly shaped rock or a man with a harelip. The tribal huaca of the Incas was the sun, and their campaigns of conquest were in a sense crusades, to elevate the tribal god to a paramount position among the neighbouring tribes. They made no attempt to suppress local cults, but planted temples to the sun in conquered provinces and compelled the subject tribes to conform, at least outwardly, to the state religion. Lowest in the order of huaca came the personal and household fetishes, known as conopa on the coast and chanca in the highlands, usually small stones of peculiar shape or colour, or any unfamiliar object. Many of the ruling Incas possessed personal fetishes or "familiars," called huauqui.

Throughout the region the cult of the dead occupied a very important place in religion. Many of the tribal and clan huaca were regarded as ancestors, and a similar sanctity attached to the mortal remains of human forbears. The burial rites afford an interesting parallel with those of Egypt. The Egyptian process of mummification arose from the local climatic conditions. The fact that bodies buried in dry sand did not decay led to the idea that the preservation of the body was a matter of importance, and so to the evolution of special means to arrest corruption. The dry air of the highlands in Peru and Bolivia and of the coast provided a parallel environment and produced similar results. In either region the bodies of the dead became desiccated, and in certain instances the preservative tendencies of the climate were assisted by the evisceration of the corpse before burial. The body was usually arranged in a contracted position (unlike the Egyptian mummy) and, after being wrapped in various folds of textile or netting, deposited in a cave (highlands) or a communal grave or "churchvard" (coast). The "mummies" of the ruling Incas were preserved in the great sun temple at Cuzco, where they were seen by the first Spanish invaders. These mummies were huaca of a high order, and those of important persons were paraded at certain festivals to the dead. The word huaca exists today as applied to the temple ruins and to the aboriginal burial grounds.

Arts and Crafts.—The skill of the ancient Peruvians in stone masonry has already been described in the section on architecture. Although stone carving is associated with some of the highland temples, sculpturing as such was not advanced; the carvings were largely confined to incision and low-relief decoration on flat surfaces. The Incas were particularly skilled in making stone bowls, club heads, axes and other artifacts.

Gold, silver, copper and tin were obtained by panning and pit mining and reduced and refined in furnaces. Some metals were used in the pure state, but alloys of gold and silver, copper and gold, and copper and tin (bronze) were also made. The metals were fashined into utilitarian objects, such as points for digging sticks, pins, knives and axes, or worked into decorations and ornaments, such as breastplates, face masks, ear plugs and necklaces. The Inca (that is, the ruler) dined on gold and silver service and had gardéns in which flowers were imitated in the precious metals. The metals were hammered, cast in open and closed moulds and shaped by cutting and joining. Several methods of soldering were

practised, and the art of gilding copper was also known.

The potter's art was highly advanced, and ceramics furnish the best basis for archaeological distinctions of regional cultures and time periods, since they not only present different styles of decoration but also are well preserved both on the coast and in the highlands. The pottery of the earliest periods, particularly Chavin, is thick, dark monochrome coloured and decorated largely by incision, punch and scratching. The later periods are characterized by panted designs in from one to eight or more colours.

The most distinctive and artistic ceramic styles are found in the Classic period of high technological development. The Mochica ceramics are characterized by their excellent modelling and highly realistic bichrome painting in red on a cream-white base. The vessels were commonly made in moulds, unlike other areas where the coiling technique was generally employed. The so-called "stirrup spout," formed by two arched tubes meeting in a single spout, is typical. The modelling and the painting faithfully portray plants and animals, scenes of hunting and fishing, house types and many other aspects of the culture, including modelled portraits of the important rulers. The Nazca pottery is highly polychrome and portrays elaborate animals and stylized figures on tall goblets. and bell-shaped containers topped by two short spouts connected by a flat bridge. Recuay ceramics in the highlands emphasize variety of shape, small figure modelling and painting in a resist, or negative, technique.

The Tiahuanaco culture, which spread throughout Peru following the Classic period, is characterized by polychrome ceramics, painted in black, white and other colours on a red base. Flaring sided cups and goblets are the most typical shapes, decorated with conventional representations of pumas, condors and running human figures. Following Tiahuanaco, the ceramics become more drab. The Chimu pottery is largely of smoked blackware with emphasis on modelling but of a quality inferior to that of the ancestral Mochica. Ica, or Late Nazca, pottery lost the colour variety and imagination of the Nazca and was reduced to black, white and red painting of small geometric figures largely derived from textile patterns.

Inca pottery is frankly geometric, although utilizing many colours. Typical shapes are tall collared aryballoid jars with wide loop side handles and conical bases; pedestal bowls; and shallow dishes with single curved handles ending in a modelled bird head. This characteristic pottery is found from Ecuador to Argentina and serves as an archaeological confirmation of the historical accounts of the extent of the Inca empire.

Peruvian textiles have been considered as among the finest in the world from the point of view of fineness of thread, variety of techniques and range of colours. Native cotton, wool from the llama, alpaca and vicuña, and an agave bast were the principal fibres. The loom is known as a "girdle-back" type, since the lower bar was attached to a belt which encircled the weaver's back. Shedding was accomplished with a flat weave sword and a simple heddle consisting of a stick attached to alternate warps by means of a looped cord. For the pattern tapestry weaves the weft was inserted by hand with wooden, copper or thorn needles.

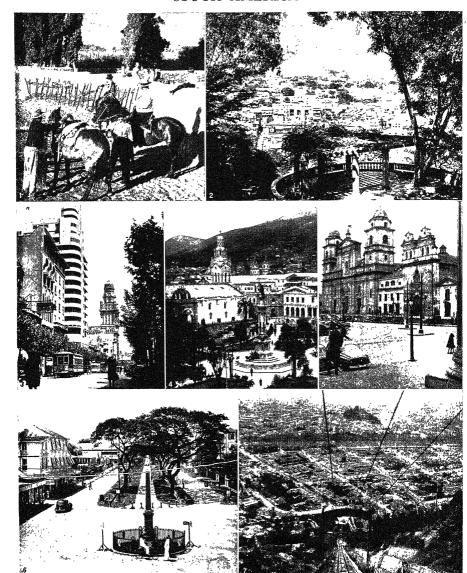

In spite of the simplicity of the loom and the weaving process, virtually every known weaving technique is represented in the ancient Peruvian collections. Plain weaves are decorated with simple warp or weft stripes, ginghams, and with such applied techniques as embroidery, feather mosaic and attached metal or shell bangles. Tapestries are outstanding in fineness of weave, and, although many methods of interlocking colour areas were known, the vertical slits were frequently left open as part of the design (like the oriental kelim). Warp and weft pattern weaves, gauze, brocade, tie dye and ikat dye are not uncommon.

The textiles from the Nazca region (particularly the Paracas site) are characterized by elaborate polychrome embroidered designs, and complex fringes of needle knitting. The Tiahuanaco period specialized in tapestry techniques. In the Late Chimu period a double-faced cloth, with reciprocal patterns, was woven on a simple loom equipped with two heddles and two shed sticks; a process involving two warps and two wefts (for further details see Bibliography, especially the Lila M. O'Neale monograph).

PAINTED FOR THE ENCYCLOPÆDIA BRITANNICA

# SOUTH AMERICAN MAMMALS, BY CHARLES LIVINGSTON BULL

The mammals native to South America embrace many exceedingly interesting forms though none attain the immense size of various

Old-World and North American animals. The Illustration portrays types of several important groups.

For details see the articles on the animals shown

Al or Three-toed Sloth (Bradypus tridactylus).
 Capuchin Monkey or Sapajou (Cebus capucinus).
 White-eared Marmoset (Hapale

jacchus). 4. Great Anteater (Myrmecophaga jubata). 5. Tapir (Tapirus terrestris). 6. Capybara (Hydrochaerus capybara). 7. Hairy Armadillo (Dasypus villosus). 8. Collared Peccary (Dicotyles tajacu). 9. Jaguar (Felis onca). 10. Ocelot (Felis pardalis) .

Social Life.—The Inca rule was a form of state socialism, based on the idea that the sovereign was the earthly representative of the Inca tribal god, the sun. In the course of expansion, and the meticulous organization of conquered provinces, the Incas, from a tribe, became an official caste, constituting eventually a huge bureaucracy. The inhabitants of the highlands acquired a mentality remarkably responsive to discipline. The expansion of Inca rule was, to the populace, merely a change of overseers.

The socialistic system seems to have dated from the earliest times; under Pachacutec it was adapted to the needs of colonial expansion Eventually the empire was divided into provinces. each under the control of a hereditary curaca (often a local chief, confirmed in his office because of ready acceptance of the new regime), and a hierarchy of officials ranging from subchiefs to subordinate inspectors whose supervision was limited to a few families. Intensive supervision was a condition of the peculiar form of government. All produce, agricultural, pastoral or industrial, was fundamentally state property. Trade was practically nonexistent. Labour manual, operative and official, was state tribute, and some form of labour was exacted from every member of the community. Lands were apportioned for cultivation to the commoners, the church and the state. The produce of the state's land supported the Inca caste, and any excess was distributed according to a regular system. Public granaries were maintained by the state in many parts of the country. This system permitted an equal food supply throughout the empire; the surplus of the maize crop, for instance, in the fertile valleys, provided for the upkeep of a large herdsman population in the sterile uplands and also for the relief of drought.

Craftsmen (weavers, potters and metalworkers), though not entirely exempt from agricultural work and corvée labour (involved in the construction of roads and state buildings), were in the main supported by the agricultural population, which, in its turn, received a proportion of textiles and other manufactured goods. The distribution of raw material as well as manufactured articles was carried out on a regular system; to take one instance, the weavers received a regular allowance of cotton and llama (or. alpaca) wool, from which they were expected to produce a certain amount of woven material. Knowledge of the carefully organized interchange of produce is based mainly on Garcilaso de la Vega's account, which is probably overdrawn, but there is no doubt that the main lines are correct.

The system was perhaps less perfect than appears from his description, yet there is no question of the drastic measures employed by the Incas in the organization of conquered territory. Whole sections of the population were transferred from one part of the empire to another. Such enforced colonists were known as mitimaes, and the practice served a double purpose, political and economic. In the first place it was a safeguard against insurrection; in the second, it provided for the population of uninhabited areas. Under a system of this type a rigid population survey was a matter of first importance, and a careful census was made from time to time, the records preserved on the knotted cords known as quipus (q.v.; and see L. L. Locke, The Ancient Quipu [1923]). It was equally important that there should be no shifting of population, except under state supervision; consequently an individual born to a certain occupation in a certain locality could, in normal circumstances, neither change his trade, move from his village nor even marry outside his local group. The system involved the suppression of personality or enterprise but provided comparative security to the individual.

Behind the state organization lay the community, still imperfectly studied and obviously far older than the imposed Inca regime. Local family groups, which appear somewhat like true clans (known as ayllu), practising the cult of a common huaca, existed within the tribal complex of the Peruvian aborigines.

The administration of the enormous length of mountainous territory governed by the historical Incas necessitated rapidity of communication, and a service of professional runners was maintained; they traversed the country in relays, from rest house to rest house, along the roads which are still traceable from Quito to northern Argentina. In the highlands these tracks are often in

the form of stairways cut in the faces of precipices.

Among the populace marriage was arranged, under supervision, within the local group. But the ruler himself was limited to certain restrictions. He was allowed to maintain a number of concubines, but, according to some authors, his normal consort (coya) was his sister, who alone could bear him a successor. This seems to suggest that rank followed the female line and that Peruvian inheritance was based on a matrilineal system. Here again, chance was on the side of the Spanish invader. Pizarro arrived just at the moment of a grave politico-religious crisis. Huayna Capac had died recently. His legitimate heir, by his sister, was Huascar But a pretender, who asserted that he was the son of the late emperor by a daughter of the chief of the lately added province of Quito, had assembled a force of Ecuadorian mountaineers and, by a coup de man, had captured Huascar.

Pizarro, by means which it is difficult to describe save as sheerly treacherous, seized Atahualpa. Atahualpa gave orders for the execution of Huascar, and these orders were obeyed. The motive power behind the Inca empire therefore ceased to exist. Huascar was dead, and Atahualpa, who by force of arms might have taken his place, was a prisoner. The Inca organization was for the moment like a clock without a mainspring, though the works were otherwise unimpaired. Yet the organization was so complete that when the Spaniards by a lucky random stroke, held in their possession the person of the only possible claimant to the position of divine ruler, they were able to set the wheels going to their own advantage. Naturally there was a certain amount of opposition but Pizarro had little to face in this respect compared with Hernan Cortes. His main difficulties lay in the dissensions which arose among the Spaniards.

Allusion may be made to the system of training which was imposed on boys of prominent Inca families in the capital, Cuzco. Lads of prominent families, destined to the higher posse in administration and the army, were subjected to a severe training of a public-school nature (which the heir to the throne also underment) and submitted to severe tests. The culminating ceremony was a race from the sacred Huanacauri hill to Cuzco, after which candidates who had passed received certain insignia of nobility, including the ear ornaments which distinguished the ruling caste.

Other Cultures of South America.—Archaeological remains elsewhere in South America are less complex than in the Andean region described above. The northwestern provinces of Argentina were the centre of the Calchaquí or Diaguite culture, reflecting influences of Tiahuanaco and Inca civilizations plus certain local modifications. The Tiahuanaco and Inca influences are also in evidence in the cultures of northern Chile. Both the northwest Argentina and the northern Chile regions seem to have had a common cultural stratum, called Atacameña, older in chronological position than the Andean-influenced periods. The frequency of urn burial, particularly of children, in the Calchaquí region is in marked contrast with pre-Spanish Peru, where this mode of burial despot occur.

Archaeological remains from southern Chile and Patagonia confirm the early ethnological observations that simple nomadic hunters occupied this area. The excavations of Junius Bird in 1936-37 indicated that the territory near the Strait of Magellan had long been occupied by such hunters, since the oldest remains found were definitely associated with extinct forms of the horse and ground sloth.

The vast area of the Amazon jungle has furnished but few archaeological sites, but the elaborately ornamented urns and vessels from the island of Marajó in the mouth of the Amazon, and from the site of Santarem at the mouth of the Tapajos river, indicate fairly advanced cultures. These remains have been tentatively identified with an early Arawak people, and it seems probable that an antiquity comparable with the early Andean periods will some day be assigned to them.

The Northern Andes.—Ecuador and part of Colombia were conquered by the Incas shortly before the Spanish conquest. Quito, in Ecuador, had risen almost to the rank of a second capital of the Inca empire. To say the least, remains of Inca buildings and ceramics are abundant. Archaeological remains antedatings and ceramics are abundant.

ing the Inca conquest show that the cultures were well advanced. In Ecuador the mythological history speaks of the Caras of the coast advancing to the highlands, where they amalgamated with

the Quitu tribe and subsequently with the Puruhá.

In Colombia the site of San Agustin is outstanding for the number and variety of large stone statues. Elsewhere regional ceramic types can be isolated which show influences from the central Andes and from Central America. Particularly characteristic is a style of ceramic decoration known as "negative" painting, a technique of reservation of patterns in the ground by means of wax painting or some analogous process.

BIBLIOGRAPHY.—Detailed summaries of South American archaeology together with comprehensive references to published sources may be found throughout the six volumes edited by J. H. Steward, Handbook of South American Indians, Bureau of American Ethnology, bulletin 143 (1946–50). Vol. ii of the Handbook also contains an article on the Incas by J. H. Rowe. T. A. Joyce, South American Archaeology (1912), covers the whole continent. General coverage as well as detailed treatment of the central Andes is found in W. C. Bennett and J. B. Bird, Andean Culture History (1949). A comprehensive treatment of Andean archaeology and history, as well as an excellent bibliography of early Spanish sources, may be found in P. A. Means, Ancient Civilizations of the Andes (1931). The bulk of archaeological literature has been published in the form of monographs and articles. Some of the important journals are: Journal de la Société des Américanistes de Paris; Revista del Musco Nacional (Lima); Journal of the Royal Anthropological Institute; American Antiquity. Current bibliography is reported annually in the Handbook of Latin American Studies. The Reports of the International Congress of Americanists contain many pertinent contributions. Carbon 14 dating techniques are described by W. F. Libby, Radiocarbon Dating (1942); L. L. Locke, The Ancient Quipu (1932), analyzes the Inca knotted string records; and special textile studies are found in M. D. C. Crawford, American Museum of Natural History, Anthropological Papers, vol. xii, Lila M. O'Neale, Field Museum of Natural History, 1937) and Raoul d'Harcourt, Les textiles anciens du Pérou et leurs techniques (1934). Detailed mention of the many monographs is not possible here, but the field reports of such authors as the following may be found in the bibliographical sources cited above: W. C. Bennett, J. B. Bird, S. Debendedti, H. U. Doering, I. Jijón y Caamaño, A. Kidder II, A. L. Kroeber, R. Larco (M. D., C. Tallo, W. Uhle, L. E. Valcárcel and G. R. Willey.

## **ETHNOLOGY**

South American types of culture, which extend throughout most of Central America and the Antilles, have been divided by different authors into a varying number of areas. The present description uses the fourfold classification of the *Handbook of South American Indians:* (1) Andean civilizations; (2) circum-Caribbean peoples; (3) tropical forest tribes; and (4) marginal, hunting and gathering or prefarming tribes.

The development and differentiation of South American cultures into these four principal types and innumerable subtypes was largely autochthonous. The biological characteristics of the Indians of North and South America are very similar, and there is little doubt that South America was originally populated by migrations from North America via Mexico and Central America. Evidence of transpacific influence in native American culture is slight and cannot account for the principal cultural developments of the latter. Carbon 14 dates show that man had reached southern Chile by about 7000 B.C., when the extinct ground sloth still survived. A similar antiquity of man in North America is proved by carbon 14 dates. Both continents, however, may well have been inhabited much earlier. The diversity of South American Indian languages also proves a long separation of the groups not only from one another but from their Middle American and North American relatives.

Racial Type.—Variation in head form, stature, and other features has been regarded by some scholars as evidence of admixture of Australian, Negroid and other old world races with the basic Mongoloid race, but this theory has been questioned because substantial transpacific migrations are improbable.

Linguistic Groups.—J. Alden Mason's linguistic classification in the Handbook of South American Indians lists 66 major independent groups and 22 other groups which are unclassifiable on the basis of present information. Future analysis will undoubtedly greatly reduce this number, but the position of many extinct

groups can never be known. No South American languages have been proved to be related to any old world languages, nor, with the exception of certain Central American dialects, to any North American languages.

Central American stocks of Mexican and North American affiliation are Subtiaba and Maribichicoa, belonging to Hokan-Siouan; Nahuatl and Aztec, belonging to Utaztecan; Lecan, Jicaquean and Payan, all possibly belonging to Macro-Penutian; and several dialects of Macro-Otomaguean.

The following languages are limited to South America. The phyla, each of which includes several stocks, are Macro-Chibchan, Macro-Ge, Macro-Guaicuruan and Macro-Tupi-Guaranian. The lesser families or stocks are:

Alacalufan Araucanian Arawakan Ataguitan Auakean Bororoan Cahuapanan Calianan Canichanan Carajan Cariban Caririan Catukinan Cayuvavan Chapacuran Charruan Chiquitoan Chonan (Tehuelche-Ona) Comechingon-Savavironan

The Central Andes.—The Indians of Peru and Bolivia achieved the highest native civilization of South America. Their archaeological remains, which are dated with fair accuracy by carbon 14, show prehistoric development in some detail.

Pancararuan

Prior to 3000 B.C., the Andes were sparsely populated by hunters, gatherers and fishermen. The first farmers lived in small, independent villages, growing Canavalab beans, gourds and cotton and making bark cloth, pottery and twined or finger-woven fabrics. Genetics show that the cotton had a south Asian ancestor, which is certain proof of transpacific influence.

Between 1000 B.C. and the time of Christ, the Andean people began to cultivate several indigenous American plant domesticates (mais-quash, Phaseolus beans, peanuts and perhaps manioc), and they domesticated the llama as a source of wool and meat and as a beast of burden. They wove textiles on true looms and invented metallurgy, first in gold and later in copper. Expansion of agricultural production required intervillage co-operation in construction of irrigation works. Religious temples built upon mounds were perhaps the centres of theocratic states, but these states were also militaristic as evidenced by weapons and certain burials which contain warrior-priests

During the millennium after Christ, generally known as the era of regional florescence, a series of localized, theocratic-millitaristic states developed throughout the central Andes. The largest mounds and temples were built, and the finest work in metallurgy, ceramics, weav-

ng, painting, sculpture and other arts was produced.

About a.b. 1000 most of the central Andes may have been brought under a single empire centring at Tiahuanaco in Bolivia, after which local states regained independence until the conquest by the Quichuaspeaking Incas began in the middle of the 15th century. When the Spaniands arrived in 1532, the Incas controlled the Andes from southern Colombia to northern Chile. The empire was highly centralized under the absolute authority of the Inca, the divine ruler and son of the sun-god. Rulers of formerly independent states were kept in power but became subservient to the Inca royal family. Local forms of religion—household and village shrines and state temples—were made secondary to the imperial sun temple, which was served by a large priesthood and to which convents of virgins were dedicated.

Inca (q.v.) society was rigidly class structured. Under the Inca, who was so exalted that he might marry only his sister, were the nobles, which included the royal family and local rulers. Below these were the common people who tilled special plots of land for the sun temple, for the state and for themselves; who provided soldiers for the conscript armies; and who supplied special artisans and servants for the nobility. The commoners were rigidly controlled and had little chance to improve their status.

to improve their status.

Inca economy was based upon irrigation agriculture. Canals watered miles of terraced mountainsides as well as valleys. There were more than 50 domesticated plants including potatoes and quinoa, the high-allitude staples; maize, beans, pumpkins and others in the middle and low altitudes; and sweet potatoes, pineapples and many fruits in the lowlands. Starchy vegetables and fruits were fermented to make

chicha, a beer. Coca and tobacco were cultivated, but these drugs had religious uses.

had religious uses.

The Incas were builders, producers and organizers rather than intellectuals and aesthetes. They built huge mounds, palaces, temples, cities and irrigation works and linked their empire with roads and suspension bridges. They produced superb textiles and ceramics, ceremonial and art objects of gold, silver and copper, and weapons of bionze in quantity and in standardized forms. They organized an empire of more than 6,00,000 people. But they never achieved writing, calendrical systems or aesthetic skills such as those of Meao-America. They never here wirm the wheel more sales in the standardized forms. They never knew iron, the wheel, porcelling glass and many other old world accomplishments. Whatever influence came from the old world—penhaps cotton, calabashes, bark cloth, the blow gun and a few others—were isolated items and did not constitute a basic part of native civilization.

civilization. The Circum-Caribbean Culture.—This culture was distributed through Central America and Colombia, especially among Chibchanspeaking peoples, in Ecuador, among the Timoteans (q v) in western Venezuela and among the Arawakans (q v) in the Greater Antilles. The culture was adapted principally to the highlands Some lowland articulates of this type, but others had a tropical forest culture, constituting enclaves within the cucum-Caribbean area.

This culture resembled that of the tropical forests in its palisaded villages, thatched houses, household furniture and farming pattern (but many tropical fruits were grown in addition to root crops). It was distinctive in its state organization and its possession of many traits derived partly from Meso-America and partly from the Andes: metal-lurgy in gold, copper and several alloys, working of precious stones, monumental stone sculpture, construction of roads and bridges, agri-cultural terracing, temple mounds, human sacrifice and ritual can-

The circum-Caribbean states were based either upon conquest, as in the case of the Chibcha or Muisca of highland Colombia, or upon confederation, as exemplified by the confederacy of the Pancent, Fincent and Centifens of northern lowland Colombia. The supreme and usually hereditary ruler held great power and high status manifest by his many servants and wives or concubines, his travel in a litter, the obeisance accorded him by his subjects and the burial of his body together with accuted film by suggests and the both of his body opening must be followed by the luxury goods and the bodies of his retainers. A class of nobles held hereditary status in some areas but more often achieved status in two ways. First, men with supernatural powers became priests who conducted religious rites and human sacrifice in special temples. Second, successful warriors gained prominence through providing war captives as victims in sacrificial rites, through displaying human trophies (scalps, skulls and whole bodies preserved and stuffed) and through adding captive women to their households as concubines and agricultural These general circum-Caribbean features were found most workers. These general circum-Caribbean features were found most typically in Colombia, Ecuador, parts of Central America and in the Venezuelan Andes. The Arawak of the Greater Antilles had small states based upon religious hierarchies, but they lacked warfare, human sacrifice, temple mounds, monumental stone sculpture and metallurgy except placer gold.

The Tropical Forest Tribes,—The tropical forest culture was

found throughout the low, humid rain forests of the Amazon and Orinoco basins, coastal Venezuela, the Lesser Antilles, coastal Brazil and parts of Central America and Paraguay. It included many linguistic groups, the most widespread of which were Arawakan, Cariban (q.v.)

and Tupi-Guaranian (see Tupian).

Tropical forest tribes characteristically farmed root crops such as manioc, sweet potatoes and species of Diaccorea, but they also grew maize, beans and peanuts. To remove the poison from the bitter species of manioc, the most important native crop, they used a basketry squeezer. Because of soil exhaustion farm plots were cleared anew every few years by the slash and burn method: trees were ringed and burned and the crops planted between the stumps. To supplement the starchy vegetable diet, fish, turtles and manatees were taken in the rivers, and wild game was hunted in the forests with spears, bows and blowguns.

Villages were fairly permanent, usually being located on rivers, and they were often palisaded. Each consisted of one or more large, pole-and-thatch houses. The household typically consisted of a patrilineal lineage (that is, several families related through the male line), but in the Guianas it was matrilineal. Patrilineal clans occurred among the Mundurucu. Community chiefs were often shamans, whose authority was backed by supernatural power. The shaman generally devoted himself to curing sickness, but in some areas he presided over com-munity rites held for such purposes as crop fertility.

munity rites held for such purposes as crop fertility.

Warfare was a major preoccupation among some but not all tropical forest tribes. The Yagus of the upper Amazon did no fighting. Tupinamba warriors took prisoners whom they tortured and ate. Scalps were commonly taken, but headhunting was more limited. The shrunken heads made by the Jivaro of eastern Ecuador gave special powers to the takers. No tribes fought to conquer territory, and few took slaves.

Birth, puberty and death rites were common. Many tribes practised Birth, puberty and death rites where common. Many times practised the couvade, whereby the husband is confined for a certain period after childbirth. Puberty initiations variously included ant ordeals, especially for men, the cutting of hair, whipping and imbibing drugs. Earth burial, turn burial and cremation were practised in different areas. The material adjuncts of tropical forest life included hammocks,

dugout canoes, twilled and checker basketry, loom weaving, ceramics, wooden stools, rubber balls and syringes and bark cloth. Many body

wouden stoods, rudder data stringes and dark rudth. Many body ornaments were worn, but clothing was scant.

The Marginal Cultures—Cultures based on hunting, gathering and fishing occurred in areas unfavourable for digging-stick farming—the grassy pampas, arid Patagonia, the cold Chilean archipelago, the arid eastern Brazilian highlands and certain isolated areas scattered around the headwaters of the Amazon. These areas were sparsely populated, the social groups were small and generally based on kinship ties, the settlements were impermanent and shifted seasonally, the religion was largely shamanistic, and warfare consisted only of personal feuds or defensive fighting. The marginal tribes typically lacked ngon was laigely snamanistic, and warrare consisted only of personal feuds or defensive fighting. The marginal tribes typically lacked farming, domesticated animals (except the dog), pottery, loom weav-ing, metallurgy, permanent houses, religious structures, social classes, political institutions and leadership superceding informal kinship controls, group religious observances, priests and warfare for conquest or tribute

Subdivisions of the marginal tribes include the archipelagic tribes, Subdivisions of the marginal tribes include the archipelagic tribow, which lived in family groups, travelling the coast in bark canoes and subsisting upon shellfish and sea fowl; the Pampean tribes of Tierra del Fuego and Patagonia, which were guanaco hunters, grouped in small, patrilineal, patrilocal, exogamous bands of 50 or 60 persons; the Gespeaking tribes of eastern Brazil, which were small-scale farmers and were notable for their proliferation of moieties or dual groupings within each village for purposes of games and ceremonies, of age-grade so-cieties of men and of men's houses The marginal tribes around the headwaters of the Amazon were isolated groups that had failed to borrow farming, permanent houses, dugout canoes, weaving, ceramics and other features characteristic of the tropical forests.

SOUTH AMERICAN LANGUAGES. The languages of South America are for the most part still very imperfectly known, and the number of linguistic stocks considered independent of and unrelated to any linguistic family in the New or Old World is reckoned at 75.

For many of them we have only vocabularies, often very scanty and of doubtful accuracy. Grammars are rare and nearly all compiled on the model of Latin by missionaries who did not realise that the methods of Latin are totally unsuited for describing languages with essentially different structure and syntax. Finally for most of the languages we have no ancient material. On the Pacific side the main languages are as under:

Chibcha was once spoken almost all over Colombia up to the frontier of Nicaragua and northern Costa Rica, with representatives as far as the latitude of Guayaquil in Ecuador, prior to the Inca invasion, when Chibcha speech was ousted by Kichua

on the Andean Ecuadorian plateau.

Kichua.-The language of the Inca, Kichua or Runa-Simi, is still spoken by Indians on the high plateau of Ecuador and Peru, in Bolivia (Cochabamba, Chuquisaca and Potosí), in the northwest of the Argentine (Jujuy, Santiago del Estero). It is the only language in America which was an element of civilization before the Discovery, when it was the instrument of an invading culture brought by an organized conquering people. Inca imperialism forced it on the vanquished peoples, then the Catholic missionaries completed the work of the overlords of Cuzco.

Aymara. Speakers of Aymara exist in Peru (in two provinces of the department of Puno and in the departments of Arequipa and Moquegua) and in Bolivia. Before the spread of Kichua it was more widely diffused and the builders of the famous monuments of Tiahuanaco almost certainly spoke it.

Araukan .- This language still exists in Chile between the Pacific and the Andes, between the 27th and 43rd degrees of latitude and in the Argentine up to Buenos Ayres.

Choko was spoken on the Pacific side between eight and four degrees North and Esmeralda on the north coast of Ecuador.

On the Atlantic side at the time of the Discovery the people were at a low level of civilization and we find there several large language families and a great number of small independent groups:

Tupi-Guarani.-In the north this language was spoken in Guiana (Oyampi and Emerillon), in the west up to the slopes of the Andes and in the plains west of the Bolivian Grand Chaco (Chiriguano). Southward it is still spoken throughout Paraguay. In the east, tribes of this speech, at the time of the Discovery,

occupied the largest portion of the Brazilian coast up to the mouths of the Amazon.

Old Tupi or Abañeenga had two dialects, that of the south or Guarani, the parent of modern Guarani, as still spoken in Paraguay and adjoining territories, and the northern, Tupi, the forerunner of modern Tupi or Neengatu, the "lingoa geral" used in commerce and missionary work throughout the Amazon basin.

Carib .- A wider area was covered by the Carib, whose place of origin is thought to have been the region between the Upper Xingu and the Tapajoz, whence they spread northwards to the Lesser Antilles and to the southernmost point of Florida. They reached the Andes on the west and small groups entered Colombia (Motilon, Opon and Carare Indians) and Peru in the Jaen area (Patagon). On the east they found the coast at Guiana (Oyana, Rukuyen, Kaliña, Galibi, etc.).

Arawak.-The Arawak area is almost identical with that of the Caribs, and in some cases they seem to have migrated together. Their centre of dispersion was somewhere in the Venezuelan-Brazilian area, about the basins of the Orinoco and the Rio Negro. Arawaks were found in Florida and southwards in Paraguay, in Peru (Uru and Pukina) and in the east at the mouths of the Amazon (Araua). So far this form of speech is the earliest of the forms found in the Peruvian-Bolivian area, being earlier than

Aymera, which was ousted by Kichua.

Pano.-Of the three geographical groups of this family, the most important is found on the south bank of the Amazon, from the Jutahy east to the Huallaga west, on both banks of the Ucayali from its mouth to parallel 10° and the right bank of its tributary, the Urubamba, in the entire basin of the Upper Jurua and the sources of the Purus. The second group covers the basin of the Inambari, while the third group holds the banks of the Mamore, the Beni and the Madre de Dios between qo 15' and 12° 30' latitude and 64° 45' to 67° 30' longitude.

Ge .- This family probably represents one of the oldest elements in South America and extends over the whole of the southern half of the Brazilian plateau reaching Xingu on the west and the Atlantic coast on the east, whence its speakers were expelled by Tupi-Guarani in the 15th century. The classification of Ge speech has yet to be accomplished and is one of the most urgent linguistic

tasks awaiting the Americanist.

Tukano.—The first or eastern of the three geographical groups of the Tukano family covers the basins of the Uaupes, Curicuriary and Apaporis The western group occupies the entire basin of the Napo from its junction with the Amazon up to the mouth of the Aguarico, along the latter river, along the Putumayo from its source to its junction with the Yaguas, along the upper Caqueta to about the 74th degree longitude. The northern group is found at the sources of the Manacacia, a tributary of the Meta.

Katukina .-- An immense area south of the Amazon between 72° 30' and 62° 30' longitude and between 4° and 9° latitude is

occupied more or less continuously by this family.

Puinave.-Like the Ge group the speakers of the Puinave languages are among the most primitive peoples of South America and represent a very ancient element of the population. The Puinave are found in the basin of the Inirida and the nomadic Maku between the Rio Negro and the Yapura, between 69°30' and 61° 45' longitude.

Guaykuru.—The Guaykuru languages are spoken by a series of tribes along the banks of the Paraguay, the Parana and their tributaries and in the Chaco, e.g., Mbaya-Guaykuru, Guachi,

Payagua, Toba, Mokovi, Abipon.

Matako-Mataguayo.-In the lesser Chaco a compact group

Matako-Mataguayo.—In the lesser Chaco a compact group is formed by the following: Mataguayo, Matako, Vejoz, Choroti, Ashluslay, Tanguages.—All over the western portion of South Am and are spread isolated languages, such as Jirajara, Timote, Tanguages, Gugatibo, Saliba, Maku, Shiriana, Auake, Kaliana, Gugatibo, Saliba, Maku, Shiriana, Auake, Kaliana, Gorje, Kofane, Zaparo, Chirino, Kahuapana, Cholona, Amuesha, Tomeri, Leko, Moseten, Yurakare, along the eastern slopes of the Andes and the upper tributaries of the Amazon from acuthern Colombia to Rolivia: Wittor Yur and Mura on the southern Colombia to Bolivia; Witoto, Yuri and Mura on the

upper and middle Amazon; Mobima, Kayuvaya, Kanichana, Itonama, Chapakura, Mashubi, Huari, Nambikuara, Karadja, Trumai, Bororo, Chiquito, Guato, Samuku, Maskoi, Enimaga and Shavante in central and southern Brazil, in eastern Bolivia and in Paraguay; Kariri in eastern Brazil; Charrua formerly spoken in Uruguay; Vilela-Chulupi, Sanaviron, Allentiak, Het and Puelche in the Chaco and in the Argentine Plain.

Australian Affinities .- Of the three southernmost languages of the continent, Alakaluf, Yahgan and Chon, only the last, now spoken by the Patagonians or Tehuelche of the Argentine l'ampa, and by the Ona in Tierra del Fuego, has been identified and is found to belong in respect of vocabulary to Australian languages. The migration of Australians to America must have taken place via the Antarctic during the post-glacial optimum when the climate of those regions was sensibly more favourable than now, a period counted by geologists as not less than 6,000 years distant. (Rivet, Bulletin de la Société de linguisthat de Paris, t. xxvi. 1-2, pp 23-63, 1925; Compte-rendu sommaire des si ances de la Société de bio-géographie, Paris, 3éme année, no. 18, séance Feb. 19, 1926)

Although links have been established with Australia and in the north with Malayo-Polynesian Australasian (e.g., the Hoka group) and with Sino-Tibetan (e.g., the Na-Dene group), linguists have failed to prove any relationship between the languages of North and of South America or with those of Central America. Information is also needed about the dying languages before they have completely disappeared.

SOUTHAMPTON, HENRY WRIOTHESLEY, 3RD EARL OF (1573-1624), one of Shakespeare's patrons, was the second son of Henry Wriothesley, 2nd earl of Southampton, and his wife Mary Browne, daughter of the 1st Viscount Montague. He was born at Cowdray House, near Midhurst, on Oct. 6, 1573, and succeeded to the title in 1581, when he became a royal ward, under the immediate care of Lord Burghley. He entered St. John's College, Cambridge, in 1585, graduating M A. in 1589; and his name was entered at Gray's Inn before he left the university. At seventeen he was presented at court, where he made friends with the earl of Essex, and received extraordinary marks of the queen's favour. He became a munificent patron of poets. Nashe dedicated his romance of Jack Wilton to him, and Gervase Markham his poem on Sir Richard Grenville's last fight. His name is also associated with Barnabe Barnes's Parthenophil and Parthenope, and with the Worlde of Wordes of John Florio, who taught him Italian. But he is best known as a patron of the drama and especially of Shakespeare. Venus and Adonis (1593) is dedicated to Southampton in terms expressing respect, but no special intimacy; but in the dedication of Lucrece (1594) the tone is very different. "The love I dedicate to your lordship is without end ... What I have done is yours; what I have to do is yours; being part in all I have, devoted yours." Nicholas Rowe, on the authority of Sir William Davenant, stated in his Life of Shakespeare that Southampton on one occasion gave Shakespeare a pres-

If the sonnets were addressed to Southampton, the earlier ones urging marriage upon him must have been written before the beginning (1595) of his intrigue with Elizabeth Vernon, cousin of the Earl of Essex, which ended in 1598 with a hasty marriage that brought down Queen Elizabeth's anger on both the contract-

ing parties, who spent some time in the Fleet prison.

ent of £1,000 to complete a purchase.

Meanwhile in 1596 and 1597 Southampton had accompanied Essex on his two expeditions to Cadiz and to the Azores, in the latter of which he distinguished himself by his daring tactics. In 1598 he had a brawl at court with Ambrose Willoughby, and later in the same year he attended Sir Robert Cecil on an embassy to Paris. In 1500 he went to Ireland with Essex, who made him general of his horse, but the queen insisted that the appointment should be cancelled, and Southampton returned to London. He was deeply involved in Essex's conspiracy against the queen, and in February 1601 was sentenced to death. Cecil obtained the commutation of the penalty to imprisonment for life.

On the accession of James I Southampton resumed his place at court and received numerous honours from the new king On the eve of the abortive rebellion of Essex he had induced the players at the Globe theatre to revive Richard II, and on his release from prison in 1603 he resumed his connection with the stage. In 1603 he entertained Queen Anne with a performance of Love's Labour's Lost by Burbage and his company, to which Shakespear belonged, at Southampton House.

Southampton was an active member of the Virginia company's council. He seems to have been a born fighter, and engaged in more than one serious quarrel at court, being imprisoned for a short time in 1603. He was in more serious disgrace in 1621 for his determined opposition to Buckingham. He was a volunteer on the Protestant side in Germany in 1614, and in 1617 he proposed to fit out an expedition against the Barbary pirates. In 1624 to the later of the United Provinces of the Netherlands against Spain. Immediately on landing they were attacked with fever, to which both succumbed, the father surviving until Nov. 10, 1624.

There exist numerous portraits of Southampton, in which he is depicted with dark auburn hair and blue eyes, compatible with Shakespeare's description of a "man right fair." Sir John Beaumont (1583–1627) wrote a well-known elegy in his praise, and Gervase Markham wrote of him a tract entitled Honour in his Perfection (1624).

For further information see "Memoirs of Henry Wriothesley, the third Earl of Southampton," in Boswell's Shakespeare (1821), xx, 427 sqq, where many of the elegies on Southampton are printed

COUTHAMPTON, THOMAS WRIGHTESLEY, IST EARL OF (1505-1550), obtained extensive lands between Southampton and Winchester at the dissolution of the monasteries. He was made one of the king's principal secretaries in 1540, was knighted in the same year, and was created Baron Wriothesley of Titchfield in 1544. Having been lord keeper of the privy seal for a few months, he became lord high chancellor in 1544, in which capacity he beame notorious by his proceedings against Anne Askew. He was one of the executors of Henry VIII's will, and was created earl of Southampton in Feb. 1547. However, he had committed an offense in appointing four persons to relieve him of his duties as lord chancellor and he was deprived of his office in March, when he left privy council. Again in the council, Southampton helped to arrange the fall of Somerset. He died on July 30, 1550.

For the career of the 1st earl see Lord Campbell, Lives of the Lord Chancellors; E. Foss, Judges of England.

SOUTHAMPTON, a seaport and parliamentary, county and municipal borough, in the county Hampshire, England, 76 mi. S.W. of London by road. Pop. (1951) 178,326. Area 17.3 sq.mi. The town stands near the head of Southampton water, an inlet of the English channel, on a peninsula formed by the rivers Test and Itchen. It is the third largest in importance among English ports and the first in regard to passenger traffic. In AD. 43 there was a Roman settlement, Clausentum, on the east bank of the Itchen, and inscribed stones, coins, pottery, etc. have been found. Southampton (Hamtune, Suhampton) superseded the Saxon Hamtune and was a royal borough before 1086. The earliest town charter was given by Henry II, probably in 1154-55, but the borough was not incorporated until 1445. Henry VI, in 1447, created Southampton a county in itself. A charter which remained in force until 1835 was granted by Charles I in 1640. It was from Southampton that the Mayflower sailed with the Pilgrim Fathers to America. The town has returned two members to parliament since 1295. It is a quarter sessions borough. Southampton gives name to a bishopric suffragan to Winchester. Natives of the town include Isaac Watts (1674-1748), Sir John Millais (1829-96) and Earl Tellicoe (1859-1935).

There are remains of the Norman walls which were strengthened by towers and had six main gates. An old house known as King John's palace is one of the earliest 12th-century domestic buildings in England. The south (God's House gate) and west town gates date from the early 14th century; Bar gate (the north gate), as it stands, is mostly later and retains good Decorated work.

St Michael's church has an 11th-century tower and arches and a font of Tournai marble (c 1150). The spire (1745) was raised a further 9 ft. in 1877 as a mark for mariners. The priory of St. Denys, an Augustinian foundation of 1124, gives its name to a suburb by the Itchen. Netley (q.v.) abbey is 3 mi. southeast.

The old guildhall, long used as a courthouse, is over the archway of the Bar gate. Tudor house, a mediaeval merchant's residence, is the museum. King Edward VI Grammar school was founded in 1550 but now occupies modern buildings near the common. Taunton's school was founded in 1760 and is now in large modern buildings at Highfield. The University College of Southampton, evolved from the former Hartley institute, was removed to Highfield in 1914. It received its charter as a university in 1952. The town suffered severely from air raids in World War II. many houses and three-quarters of the old district in the centre having been devostated and important port installations destroyed. The civic centre, completed in 1939, comprises the new guildhall; municipal offices; police headquarters and law courts; and the public library and art gallery. The tower is a landmark for shipping and contains a clock and bells. There are a large sports ground (268 ac.), a common and several parks

The Port and Its Trade .- The modern importance of the port begins with the creation of a pier and harbour commission in 1803 and the erection of the Royal pier in 1831. The prosperity of the town was enhanced by the opening of railway communication with London in 1840. The harbour is one of the finest natural harbours in the kingdom and has the advantage of a double tide, the tide of the English channel giving it high water first by way of the Solent and two hours later by way of Spithead. In 1892 the docks became the property of the then London and South-Western railway company, now British Railways, but were taken over by the Docks and Inland Waterways executive in 1950. The older docks lie at the confluence of the Test and Itchen rivers; large modern extensions lie to the northwest of these alongside the Test river. The old docks cover more than 200 ac. and in addition to the river quays there are three large tidal basins, the Ocean dock, Empress dock and the Outer dock, leading to the Inner dock The Ocean dock accommodates the largest liners on the North Atlantic route; a modern terminal building adjoins it. The new docks, with 12 mi, of deepwater quay facing the Test river, include the King George V dry dock, one of the largest in the world.

Dock or quay	Year opened or completed	Area	Nominal dredged depth below chart datum	Length of quays	Width of en- trance
Outer Dock Inner Dock Itchen Quays Empress Dock	1842 1851 1876-95	16 ac 16 ac 18½ ac	Open at high tide only 20-31 ft. 26 ft.	2,621 ft 2,575 ft 3,346 ft 3,880 ft	150 ft. 50 ft. 165 ft.
Test Quays and South Quay Ocean Dock New Docks	1890-1902 1911 1934		307,32 ft. 40 ft 40 ft.	4,679 ft 3,807 ft 8,014 ft	400 ft.

Southampton is England's chief port for express transatlantic services and is also used by ships bound for South America, East Africa, Australia, New Zealand and the far east. There are cross-channel services by British Railways ships and a ferry to the Isle of Wight. Southampton airport is at Eastleigh, 5 mi. northeast. Flying boat services operate from the marine air terminal.

Principal industries are shipbuilding and ship repairing, building and contracting, dock and harbour services, distribution services and marine engineering. There is also a wide range of light industries. A large new oil refinery was opened at Fawley on Southampton water in 1951.

**SOUTH AUSTRALIA**, a state of the commonwealth of Australia, occupying 380,070 sq.mi. (12.78%) in the central southern portion of the continent.

# PHYSICAL FEATURES

Natural Regions.—Situated athwart the junction line of the great western plateau and the great central plains of Australia, South Australia can be divided into a number of different physical areas. Its relief is nowhere so marked as that of the eastern states, and there is relatively little land above 2,000 ft. The northwest

quarter is occupied by the southwestern extension of the western plateau. The northeastern quarter is occupied by the Lake Eyre depression, with its horseshoe of mud and the marsh-filled depressions—"Lakes" Frome, Callabonna, Blanche, Gregory, Eyre (3,700 sq.mi.) and Torrens—surrounding the northern Flinders ranges. Southward from these lies an area where recent (Pliocene) cross-patterned warping and faulting, elevation and submergence have provided the most decisive features of the state: the Mt. Lofty-Flinders ranges, the northern part of Yorke peninsula, the Spencer gulf-Lake Torrens (semidrowned) valley; the Flinders Barrier spur or ridge, the extremities of the peninsulas, Kangaroo Island and perhaps also—though it is older—the Gawler range. South and east of this lie the Murtay river and the southeastern lowland plain, the western fringe of the great Murray (Tertiary sea basin) lowland and the counterpart of the Lake Eyre basin in the north.

The northeastern corner of the state (118,000 sq.mi.) forms part of the Great Artesian basin, the water-bearing beds lying at average depths of 4,000-5,000 ft. in the northeast but shallowing until, along the edge of the west Australian platform, the waters well up in a line of remarkable "mound springs." The soft strata of the lower Murray basin also yield plentiful supplies, often of good quality, from depths of 50-350 ft. and, toward the extreme southeast (Penola, Millicent) the underground water table intersects burface and has resulted in extensive swamps and coastal lagoons.

Climate.—The state may be roughly divided into two climatic regions, a northern warm, dry region with high summer temperatures and less than 10 in, of rainfall per annum, much of which is erratic and unreliable, and a southern region which is typically Mediterranean with moist winters and hot dry summers. Very few areas in this latter region receive more than 35 in. of rain each year. The settled part of the state averages between 15 and 25 in. Adelaide, for example, has a mean annual rainfall of just over 21 in. and is the driest state capital in the commonwealth. North of the 32nd parallel and in the eastern part of the state north of the Murray river, the mean annual rainfall is less than 10 in. but, as in most dry areas, distribution is very erratic. The driest known part of the whole continent occurs around Lake Evre. There the annual average rainfall is only 5 in., and it is rare for more than 10 in. to be recorded in any 12-month period. Generally the lake itself is dry and covered with salt.

South Australia is warm and sunny. The range of average temperature is greater in the summer than in the winter. In June, July and August most of the state experiences mean monthly temperatures between 50° F. and 60° F., whereas in the summer the southern part of the state has mean monthly temperatures around 50° F., while in the northern part of the state the monthly average is between 80° F. and 85° F. It is not uncommon at Oodnadatta for the thermometer to register 120° F. in the shade. Adelaide, on the average, has 13 days per annum when the temperature is more than 10° F.

Vegetation.—The natural vegetation consists mainly of five major types. Eucalypt woodland and forest is on the higher and wetter parts of the Mt. Lofty and Flinders ranges and in the southeastern part of the state. Mallee (dwarf eucalypt), she-cak and tea-tree used to cover the remainder of the southern portion of the state but large areas of mallee have been cleared for agriculture. In the drier north, the mallee gives way to mulga scrub (acacia) and on the fringe of the Nullarbor plain in the west, saltbush is dominant. In the northwest and northeast spinifex grass is the chief plant of the very dry areas, but in places there is no vegetation at all, but only sandy ridges or rough gibber (stony) plains.

One of the greatest changes in the vegetation pattern of the state has been the establishment of pine forests in the southeast. Pinus radiata was expected to cover 90,000 ac. by 1961. By the 1950s the forests already produced raw material for a cellulose factory, timber for packing cases as well as for buildings, and the Victorian match industry depended upon a supply of veneers produced at the government peeling plant at Mt. Burr and at a private plant at Nangwarry, 20 mi. N. of Mt. Gambier.

Soils.—The distribution of the different types of soils is naturally closely related to the climate and vegetation patterns. The podsols, or ash gray soil, are found in the wetter parts of the state where iron oxide and other soluble materials have been leached out leaving the surface soil ash gray in colour and poor in plant nutrients. Where the rainfall is slightly less and the evaporation higher the podsols give way to the red brown earths which extend north of Adelaide beyond Jamestown and in the southeast around Naracoorte and Bordertown and on Eyre peninsula. All these areas are important for agriculture and grazing. The mallee soils. rich in lime but poor in humus and phosphate, are closely associated with the mallee type of vegetation. With the application of superphosphate and some of the important trace elements (copper, zinc and molybdenum) many of these mallee soils, once thought to be of little economic value, are gradually being sown down with subterranean clover and it is expected that they will add considerably to the pasture acreage of the state. Desert-steppe soils and desert sand hills extend over the northern half of the state, and are used for extensive grazing where artesian water : available.

Water Supply.—Climatic conditions made the provision of an adequate water supply an early problem for settlers in South Australia. Throughout the arid areas of the state, settlers were forced to rely on surface catchments and later on artesian supplies. The Murray river water was used for irrigation purposes in isolated settlements along the banks. It was not until 1944 that a double pipe line of 230 mi. was completed from Morgan to Whyalla, being used on the way for boosting several rural reservoirs. An additional pipe line from the Murray was begun in 1951 to supplement the inadequate water supply of Adelaide.

#### HISTORY

The coast line of South Australia was explored by Matthew Flinders and Nicolas Baudin in 1802. Apart from occasional visits by whalers little was done about the settlement of the area until 1830 when preliminary plans were drafted by the National Colonisation society, founded by Anthony Bacon and Edward Gibbon Wakefield. These proposals were submitted to the colonial office in the form of the South Australian Land company, the members of which were philanthropic bankers and Whig politicians. After a year's negotiations, the company's proposal was rejected by Lord Goderich because it was "too republican." With the passing of the Reform bill however, a new society called the South Australian association was formed, the committee being mostly "advanced-liberal" members of parliament. In spite of antagonism from those opposed to the theories of systematic colonization, an act establishing South Australia as a British province was passed in Aug. 1834.

Among other things the Foundation act protected South Australia from becoming a convict colony and fixed a minimum price for land, the revenue from which was to be used entirely for sending emigrant labourers to the new province. It also divided the home administration of the colony between the colonial office and a board of commissioners. A sum of £20,000 was to be raised as a guarantee fund and £35,000 worth of land sold before the province could be gazetted. The fulfilment of these provisions was made possible by the South Australian company, a joint stock venture unconnected with either government or commissioners. This company not only made the first settlement in South Australia, but also, through its banking, mercantile, land and shipping operations, played an active part in forming the policies of early governors.

The surveying party sent out to select the site for settlement was understaffed and ill-equipped and was followed too soon by the main party of settlers. The official proclamation of the province was read at Holdfast bay, by Gov. John Hindmarsh on Dec. 28, 1836. Through the resolution and foresight of Col. William Light a town site was chosen and the survey of Adelaide completed by March 1837.

The division of powers between Governor Hindmarsh and the commissioner's agent rapidly developed into factional strife, but this was greatly diminished by the appointment in 1838 of George Gawler to the dual office of queen's representative and resident commissioner. As a result of administrative difficulties, almost three years passed before the surveys were sufficiently advanced

to permit country settlement. The colonists meanwhile spent their time and substance in speculating on town lands, a process accentuated by the public works program of Governor Gawler Immigrants continued to flow into Adelaide, and because provisions had to be imported, prices soared. The commissioners' resources were exhausted by the end of 1839 in spite of the fact that they had borrowed from the sacrosanct Land and Emigration fund. An appeal to the colonial office for assistance led to an inquiry into South Australian affairs by a select committee of parliament, the report of which was not completed till June 1841. In the meantime, the commissioners were obliged to defer payment on drafts from Adelaide, immigration ceased, and the province suffered a financial collapse. By an act of 1842 South Australia was placed wholly under the control of the colonial office.

Capt. George Grey, appointed as Gawler's successor, embarked on a program of strict economy. Before he arrived the exodus of states to the country had begun, and several large flocks of cattle and sheep had been overlanded from New South Wales. By 1842, the settlers had surplus grain for export. With the development of copper mining in 1845, a second, though more limited, speculation mania broke out. The flow of migrants recommenced, hundreds of Cornish miners and their families receiving free passages to the colony. The prospects of copper production were somewhat dimmed by the discovery of gold in Victoria in 1851—more than 18,000 South Australians proceeded to the diggings. Most of them returned however to the more dependable income from the wheat fields and copper mines of their home colony.

Throughout the foundation and early years of settlement, religious and civil liberty had been given great prominence. Religious freedom found expression in "a fair field for all churches" and, except for a brief period ending in 1850, there was no state aid to religion, the denominations in South Australia being supported entirely by the voluntary principle. Secular education subsidized by the state was also introduced in 1850. Religious equality was used as an additional inducement to prospective migrants, with the result that the proportion of nonconformits sects, especially Methodists, has always been higher in South Australia than in the other Australian states and helps to account for Adelaide's reputation as "a city of churches."

The first goal of civil liberty was self-government, which the Foundation act promised when the population reached 50,000. In 1843, with the population at about 17,000, four nonofficial colonists were admitted to the legislative council, and in 1850, the population being 63,700, the province was granted a chamber of 8 crown nominees and 16 elected representatives. This blended council prepared a constitution in 1853 providing for a legislature composed of a nominated council and an elective assembly. The impatience of the colonists with the nominee system, however, was expressed in a petition to the queen bearing more than 5,000 signatures. The authorities yielded to pressure and the Constitution act of 1856 gave South Australia two elective chambers. Although a small property qualification was retained for electors to the council, adult manhood suffrage was adopted for the assembly. Other principles of civil liberty which placed South Australia in the van of empire in 1856 were vote by ballot, one man one vote and triennial parliaments. A few years later, Robert Torrens introduced a simplified system for the transfer of land titles which was later copied in many countries. In 1887 payment of members was introduced, and votes for women followed in 1894. Though the colonists maintained a scrupulous loyalty to the crown, their resentment of interference in local affairs found expression in prolonged legal disputes such as those which led to the Colonial Laws Validity act of 1865. This act gave validity to the laws passed by all colonial legislatures provided that they were not repugnant to British statutes. It remained as the legal keystone of the empire until the Statute of Westminster, 1931.

The control of crown land revenue, secured in 1856, enabled the colonial legislature to begin a more systematic exploitation of natural resources. By a vigorous immigration policy, an average of 3,000 persons a year were brought to the colony between 1860 and 1880. A number of Germans were sent out by George Fife Angas and others in the early years of settlement but the great

majority of South Australians are of British stock.

By 1860 most of the colony had been explored and pioneer pastoralists had spread as far as water supplies would permit. Behind them agriculturists speedily extended the areas of crop. A severe drought in 1865 checked the expansion temporarily, and some attention was diverted to the settlement of the Northern Territory. The development of this project proved both costly and cumbersome to the South Australian government, although a few individuals profited through land speculation and mining, and-others by cattle raising round Alice Springs. Few objections were raised when the responsibility for the Territory was taken over by the commonwealth government in 1911.

New copper mines were discovered at Wallaron and Moonta in 1860 and the Murray river shipping trade was developed to reach a peak of over £1,250,000 in 1883, after which it declined through the competition of Victorian and New South Wales railways. Most of the state's capital and labour, however, was directed toward agriculture and wool growing. A network of some 2,000 mi. of railway connected the centres of rural production with easily accessible ports, from which a large proportion of the grain was taken to Europe by sailing vessels, the annual race of these ships heing followed with keen interest. In the year 1880 South Australia through its abundant wheat production earned the title of the "farinaceous state."

Among the many new adaptations made by the early settlers for wheat growing in South Australia, John Ridley's reaping machine deserves special mention as a labour-saving device which came into general use after 1850. Dry-farming techniques and the application of superphosphates were also important factors in bringing new land under cultivation and increasing agricultural production. As the supply of wasteland diminished, however, more attention was given to scientific research, aided both by state grants and generous gifts from private individuals. The instruction given at Roseworthy Agricultural college (established in 1885) and experiments at the Waite institute (1924) have benefited the whole continent. Improved methods of tillage and a ceaseless war against pests and plant diseases have greatly reduced the risks of rural production. The pastoralists, too, have benefited. The development of a large-framed Merino sheep suited for semiarid conditions, experiments with the top-dressing of pastures and the introduction of English breeds have made possible a flourishing export trade in fat lambs.

In the first 40 years of the colony the progress of education was impeded by the wide spread of population and the emphasis on rural production. State subsidies were first granted in 1846, and a Central Board of Education established a few years later but no spectacular advance was made till 1874. In that year the University of Adelaide was founded and a few months later compulsory and secular education was introduced. This was followed by the establishment of the Teachers' Training college in 1876 and the School of Mines ten years later. In the '90s primary education was made free, and attention was given to the creation of secondary schools. Until the introduction of motor transport, however, secondary education was largely confined to the vicinity of Adelaide. The city remained the centre, not only for mercantile interests but also for culture, entertainment and sport.

Whill the federation, South Australia was noted for its frequent changes of government and the independence of its feederd representatives. This was encouraged in part by the attitude of colonists outside parliament, expressed through a profusion of small and short-lived societies for social and political reform, and in part by the extreme difficulty of reshaping electoral divisions to conform with the continual shift of population. From the beginning, care was taken to assure a high proportion of representation to the rural districts counterbalance the indirect influence of urban voters through their counterol after the respective of the parliament in Adelaide. The system of multi-member electorates also encouraged voters to support individual candidates rather than a party program. The emergence of a Labour party after the industrial troubles of the early 1890s, therefore, made but little impression on the tradition of independence, especially after the outstanding leaders transferred their attention to the federal sphere. South Australian politicians played a prominent part in the drafting of the federal constitution, some of them making a strong bid for the retention of state rights. The activity of leading milliers and bankers in establishing commonwealthwide combines after the federal government took over the control of staffs was perhaps the most important single cause of the development of the party system in South Australia. To defeat the schemes of the monopolist conservatives" in 1903, a party of Independent Liberals

was formed, and with this group the Labour party made a compact. The Conservatives were defeated but the Labour-Liberal combination proved unsatisfactory. It was soon realized that the control of fiscal policy by the commonwealth greatly reduced the power and influence of state governments. The Labour party's insistence on adult suffrage for the legislative council and the ultimate abolition of that chamber was too radical for the Liberals but it nevertheless remained the central plank of Labour's platform.

In 1910 the Labour party was returned with a majority of two in the assembly and under the leadership of John Verran formed its first South Australian ministry. This government held office for two years, but its reforms made little headway against the Conservatives in the legislative council. It had, however, become closely identified with the Australian Labour party and had taken a stand on the close unification of states within the commonwealth. Though strongly supported in the urban electorates it came to grief in 1912 on the issue of state rights and did not regain office until the outbreak of World War I when its ranks were again split on the conscription issue, more than half the members going over to the new Nationalist party which then came to terms with the Liberals.

In 1921 four parties contested the state election. There were the in 1921 four parties contested the state election. There were the remnants of Labour, the Nationalists who had parted company with the Liberals, and those who supported the Farmers and Settlers' party. After the Australian Labour party adopted the "socialization of industry, production, distribution and exchange" as its central objective, dustry, production, distribution and exchange as its centar objective, there was increasing combination between the anti-Labour groups. For the next 12 years parliamentary power alternated between Labour and Liberal In 1933 there was a strong reaction to the old tradition of independent members, chiefly because of dissatisfactions caused by the depression. It was soon realized that it was impossible to isolate the state from the parties of federal politics, especially after the creation

of the commonwealth loan council.

In 1941, therefore, fewer Independents were returned and, with the backing of the Liberals and Country party, Thomas Playford became premier. His masterly grasp of the complexities of state-federal finance earned him the leadership of the less influential states in the premiers conferences at Canberra, while at home his vigorous and imaginative developmental policies broke, to a large extent, the almost complete economic dependence of the state on rural production. In 1953 his party was elected to office for the sixth time in succession.

#### POPULATION

The growth of population in South Australia is shown in the following table:

Population of South Australia, 1850-1950

						Population (in thousands)			
Year						Metropolitan	Other	Total	
1850 1870	-			-		32 61	31 123 186	63 184 318 406	
1870						6x	123	184	
1890		:				132	186	318	
1010						199	207	406	
1930						310	207 264 285	574	
1950						415	285	700	

Adelaide, the capital of the state, had a population of 646,073 in 1947; it was estimated to have 739,563 in 1952.

# AGRICULTURE AND INDUSTRY

Agriculture,-South Australia, although third in size of the Australian states, has a relatively small area that can be utilized for agriculture. More than four-fifths of the total area has an average rainfall of less than 10 in. a year and supports fewer than 2,000,000 sheep and 100,000 cattle. The following table showing the percentage of the total sheep population carried outside the roin, rainfall country indicates the trend that has been taking place over the last 50 years.

Distribution of Sheep, 1000-1050

Year								Number of sheep	Percentage outside 10 in. line
1900		-			•	•		5,667,000	28.2
1910								6,432,000	24.9
1930		•						6,186,000	24.9 18.7
1940						• •		9,941,000	20,1
1950		٠	٠	•	•	٠	٠	9,477,000	14.8

Goyder's line of rainfall marking out the southern extent of the 1865 drought was for many years regarded as a line of safety beyond which agriculture could not be carried out. The use of dry-farming which agriculture could not be carried out. The use of dry-larming methods and artificial fertilizes has, however, brought large areas outside the line into cereal production. In the higher rainfall areas sheep rearing and cereal production predominate. Many wheat farmers turned to fat lamb production after the depression of the 1930s and by 1940 the sheep population of the state had increased to 10,000,000. More land is being put under pasture for livestock as the

result of a wider use of subterranean clover, superphosphate and modern mechanical methods of clearing. Land previously considered use-less, or able to carry as little as a quarter of a sheep to the acre, is being converted to two sheep to the acre country or better. The area sown to pasture doubled between 1940 and 1950, and if the trend in the early 1950s of 100,000 ac. a year were to continue, it would have doubled again by 1960.

doubled again by 1960. Wheat for many years has been the dominating cereal in South Australia. A peak of 4,650,000 ac. was sown to cereals in 1930-31. Of this 4,180,000 ac. were sown to wheat, 252,000 ac. to harley and 218,000 ac. to oats. Livestock then began to be more important in areas formerly devoted exclusively to cereals, with the result that by 1951 the wheat acreage had declaned to less than half that of the peak year. The yield, however, increased slightly to an average of 12 bu. per acre for the 1940-50 period, resulting in an average production of about 26,000,000 bu. There has been a considerable increase in the acreage under barley in recent years.

Dairying is carried on mainly on the plains and in the hills within reach of Adelaide where markets and export facilities exist Vines and olives thrive on the lower western slopes (below 500 ft) of the Adelaide hills, while further northeast and north the Angaston, Tarthur and Clare districts are noted for their excellent wines. Oranges, lemons, peaches, apricots and almonds abound on the plains and in the valleys where water, shelter and warmth are available Around Renmark, Loxton, Berri and Barmera on the Murray river, citrus fruits, vine crops and vegetables are grown under irrigation.

The barrage at the mouth of the Murray has maintained satisfactory levels in Lakes Albert and Alexandrina. Around these lakes and along the lower Murray there are areas that could be used for the production of fodder crops for dairy cows or for market gardens to meet the increasing demands of the growing urban population for

fresh milk and vegetables.

Mining .- Although South Australia has never been rich in precious minerals there are a number of mineral resources that are becoming increasingly important not only for the state, but for the commonwealth as well. The discovery of silver lead at Broken hill in the neighbouring colony of New South Wales was exploited by the South neignouring colony of New South Wales was exploited by the South Australians. The mines were connected by rail with Port Pirie where treatment plants were established. Among the metallic minerals iron will be significant for a long time to come. In the dry Middleback ranges west of the northern part of Spencer gulf the ore occurs in Iron Knob, Iron Monarch and several other hills and provides the raw material for the heavy industries at the near-by port of Whyalla as well as for the steel industries at Newcastle and Port Kembla in New South Wales. Conput declined in importance after the Monata New South Wales. Copper declined in importance after the Moonta New South wates. Copper declined in importance after the months mines were closed in 1923, but in the 1950s investigations were being made to discover new workable deposits.

A later nonmetallic substance to be developed is sulphur, an im-

portant raw material for the manufacture of sulphuric acid neede ever increasing quantities for the production of superphosphate. than 30,000,000 tons of pyrites—enough to produce 3,000,000 tons of sulphur—had been discovered at Nairne in the Adelaide hills by 1953. Gypsum, one of the state's mineral products since the 19th century, had become the basis for the manufacture of plaster of paris for the building industry. The state is the main producer of salt in the commonwealth, and besides the deposits on Yorke and Eyre peninsulas, large areas of flat land on the coast north of Adelaide are being used for the production of salt by flooding and evaporation on a large scale. The coal deposits at Leigh Creek, 350 mi. N. of Adelaide, have been developed as a state undertaking, and in 1953 it was hoped that the annual output would soon reach 1,200,000 tons, and so supply the state with a fair percentage of its needs. The field has been proved state with a rain pertensage or its needs. The neith as been provent to contain not less than 380,000,000 tons of subbituminous coal with a moisture content between 30% and 40%. Limestone in all grades and of the purest quality is worked in various parts of the state. Important recent discoveries include high grade cosmetic tale in the north Filinders range and uranium or at Radium hill and Mt. Painter.

Industry—Datil its centenary in 1936, South Australia was essentially a primary producing state. However, after 1936 there was a remarkable development of secondary industry, and employment in manufacturing in 1933 far exceeded that in agriculture. This development received active encouragement from the South Australian government and was stimulated during World War II when munition factories of many kinds were established.

Manufactures of every description are undertaken, ranging from motor bodies to textiles, from consumers' durables to steel tubes. At Whyalla, a modern blast furnace and shipyards have been established, and at Salisbury there is the headquarters of the Long-Range Weapons establishment. The latest developments include industries associated with the processing of uranium ores. All this growth in manufacturing production has been assisted by improved power supplies, made pos-

production has been assisted by improved power supplies, made possible by the use of Leigh Creek coal deposits.

The rapid increase in factory employment between 1938–39 and 7949–50 illustrates the industrialization of the state. Over this period factory employment increased by 84%, as compared with an increase of 17% in the state's population. By the 1947 census 37% of male breadwinners were engaged in secondary production, whereas only 22% were in primary production, the remainder being involved in the service industrics. This emphasizes the remarkable shift in the balance

between primary and secondary production.

BIBLIOGRAPHY.—The most complete work on South Australia is The Centenary History of South Australia, prepared by the Royal Geographical Society of Australiasia, South Australian branch (Adelaide, 1936). The Proceedings of the South Australian Royal Geographical Society (Adelaide, 1838—) contain many valuable studies. See also E. Hodder, The History of South Australia from Its Foundation to the Year of Its Jubilee, 2 vol. (London, 1804); A. Grenfell Price, The Foundation and Settlement of South Australia, 1829–1845 (Adelaide, 1924); C. E. Fenner, South Australia, Geographical Study (Melbourne, 1931). (P. H. K.; G. H. LN., D. H. PE.)

SOUTH BEND, a city of northern Indiana, U.S., county
seat of St. Joseph county; 86 mi. E. by S. of Chicago, Ill., at the "south bend" of the St. Joseph river, where it turns northward to Lake Michigan. It is on federal highways 20, 31 and 33 and is served by the Grand Trunk, the New Jersey, Indiana and Illinois, the New York Central, the Pennsylvania, the Chicago, South Shore and South Bend (electric) railways, and by major air lines. The production was 115,698 in 1950 and 101,268 in 1940 by the federal census. The city has an area of 19.7 sq.mi. Industries include automobiles and accessories, aviation products, agricultural implements, toys, paints and varnishes, sewing machines, lathes, baits and fishing rods, steel ranges, home laundry machines, folding cartons and boxes, men's and women's wear, bearings, special machinery and tools, wallpaper, wastepaper baskets, metal furniture, elastic and surgical goods, electrical equipment, brass, iron and semisteel castings and dress patterns. South Bend is surrounded by rich peppermint-growing muck, which also produces potatoes, celery and onions, besides various truck produce. Dairying is important. The water supply comes from about 115 wells, and electric energy is supplied by steam and hydroelectric plants. La Salle and Father Marquette were the principal figures in South Bend's early history. South Bend's best-known educational institutions, the University of Notre Dame and St. Mary's college and academy, were both founded by the Congregation of the Holy Cross. A trading post for the American Fur company was established in 1820 and settlers came in 1823. In 1831, when the population was 128, a town was laid out. It was incorporated in 1835 and chartered as a city in 1865. The population was 1,652 in 1850, after which it grew steadily and substantially.

SOUTH BOSTON, a city of Halifax county, Va., U.S., on the Dan river, 30 mi. N.E. of Danville. It is served by the Norfolk and Western and the Southern railways.

The population was 6,079 in 1950 and 5,252 in 1940 by the federal census. Tobacco, corn and wheat are grown in the area, and the city has condensed milk plants, a bottling works, a foundry, flour mills and tobacco processing plants.

Under the city's council-manager form of government, the mayor and the six members of the council are directly elected for terms of two years. The city owns and operates a water works.

South Boston has the Carrington Memorial Public library, and two weekly newspapers are published there. The South Boston Hospital, Inc., was established in 1943.

SOUTHBRIDGE, a town of Massachusetts, U.S., on the Quinebaug river. Pop. (1950) 17,511; (1940) 16,825 by the federal census. The river falls 165 ft. at this point, furnishing abundant water power. Optical goods are its most distinctive product. In 1801 a poll parish (popularly called Honest Town) was formed from parts of Charlton, Dudley and Sturbridge; and in 1816 it was incorporated.

SOUTH CAROLINA, popularly called the "Palmetto state," is an Atlantic coast state of the U.S., and one of the original thirteen. Its area is 31,955 sq.mi., of which 461 sq.mi. are water. It lies between the extremes of approximately 32° 4′ and 35° 12′ N. and 78° 31′ and 83° 32′ W.

Physical Features.—South Carolina is mainly in the coastal plain and Piedmont plateau regions, but in the northwest it extends slightly into the Appalachian mountain region. Locally the coastal plain region is known as the low country, and the Piedmont plateau and Appalachian mountain regions are known as the upcountry. The coast is low, and islands increase in size and number toward the Georgia border. For about ro mi. inland the coastal plain is occupied largely by salt marshes. Then, although continuing flat, the surface rises at the rate of about 2 ft. per mile for

50 mi. or more. Parts of the Blue Ridge rise abruptly from the foothills to 3,436 ft in Mt. Pinnacle, 3,218 ft. in Caesar's Head and 3,124 ft. in Table Rock. The highest point in the state is Sassafras mountain (3,560 ft.) in the Blue Ridge and on the North Carolina state line. The mean elevation of the state is about 350 ft.

The principal rivers rise in the Appalachian mountains and flow southeast into the Atlantic ocean. Santee river is formed by the confluence of the Wateree (known above Wateree creek north of Camden as the Catawba) and the Congaree, which is in turn formed by the Broad and the Saluda. The basin of this system embraces about half the area of the state. In the northeast the Waccamaw and the Pee Dee and its tributaries—the Little Pee Dee and Lynches—are wholly within the coastal plain, but the main stream of the Pee Dee is a continuation below the fall line of the Yadkin river which rises in the mountains of North Carolina. The Edisto is the principal stream in the southeast.

In the Piedmont plateau there are rapids, but in the coastal plain the current becomes sluggish, and in time of high water the rivers spread over wide areas

Flora.—Palmettos grow on the coast but only artificially inland. For some distance from the coast there are magnolias, live oaks draped with long gray moss, and reed-covered marshes. In the swamps are cypress, gum and bay trees.

In most of the uplands of the coastal plain the longleaf rine is predominant, but large water oaks and undergrowths of several other oaks and of hickories are not uncommon. On the Piedmont plateau and in some of the more hilly sections below the fall line there is some shortleaf pine, but most of the trees in these areas are hardwoods. Deciduous oaks are most common, but beech, birch, ash, maple, black walnut, chestnut, sycamore and yellow poplar also abound. On the mountains are oaks, chestnut, laurel, white pine and hemlock. Among indigenous trees, shrubs and vines are the blackberry, grape, persimmon, plum, crah apple, hickory, chestnut and hazelnut.

CHmate.—Along the coast the climate is mild and equable. At Charleston, the mean winter temperature is 51°, the mean aumer temperature 80°, the mean annual temperature 66° and the range of extremes from 104° to 7°. For the state the mean temperature is about 63°. In nearly all sections January is the coldest month and July the warmest. Aiken, near Augusta, Ga., has a very mild winter season and is a popular resort. The mean annual rainfall for the state is about 47.75 in and its distribution is excellent. Seventeen inches fall during the summer. Snow is uncommon in the southeast but elsewhere there may be several inches, occasionally more than a foot.

The frost-free season ranges from 245 days on the coast to 204 days on the uplands. Tornadoes sometimes occur in the west and the coast suffers from hurricanes.

Soils.—In general the soils of the Piedmont plateau are such as have been formed by the disintegration of the underlying rocks. These consist mostly of granite and gneiss, but in the north central section there is traprock and in the southeast section some slate. On the Piedmont plateau the subsoil is a reddish or yellowish clay. In the upper section of the coastal plain the soil is for the most part a loose sand, but near the coast it becomes more fertile, much being underlain by marl.

History.—The history of South Carolina may be divided into the periods of discovery and exploration (1521-1670), proprietary rule (1670-1719), royal rule (1720-75) and statehood (from 1776). The first Europeans to visit the coast were a party of Spaniards from Santo Domingo in 1521. The first settlement was made by Spaniards under Lucas Vásquez de Ayllón in 1526, but after a few months it was abandoned. The Spaniards, again settling in 1566, maintained a fort on Parris Island for about 20 years. In the meantime (1562) French Protestants under Jean Ribaut made an unsuccessful attempt to establish a colony on Parris Island (see Port Royal). In 1629 Charles I granted to his attorney general, Sir Robert Heath, all the territory lying between the 31st and the 36th parallels and extending through from sea to sea, but no settlement was made, and in 1663 the same territory was granted to the earl of Clarendon (1609-74) and seven other favourites of Charles II. A second charter in 1665 extended the limits to 29° and 36° 30′. The proprietors were to legislate for the province "by and with the advice, assent and approbation of the freemen." They were empowered, though not required, to grant religious freedom to dissenters. Circulars were issued in 1663 and 1665 offering most liberal terms to prospective colonists. In the fundamental constitutions adopted by the proprietary board in 1669, John Locke and Lord Ashley (1621–83) prepared for the province an elaborate reducal system of government which would have been obsolete even in Europe. The colonial assembly refused (as the charter gave it the right to do) to adopt them. They were, nevertheless, an element in arousing the feeling of discontent among the colonists which culminated in the overthrow of proprietary rule, and they encouraged the large-plantation system which constituted the foundation of the slaveholding aristocracy.

The first permanent English settlement was made in April 1670 at Albemarle point on the west bank of the Ashley river, but as the situation proved unfavourable the government and most of the people moved over in 1680 to the point between the Ashley and Cooper rivers, the site of the present city of Charleston. The area of settlement was gradually extended along the coast in both directions, but did not penetrate far into the interior. There were many English from Barbados and French Protestants, both of whem strongly influenced the history of the province.

South Carolina's political history during the colonial era is the story of a struggle between popular and prerogative interests, first between the people and the lords proprietors, later between the people and the crown. From 1670 to 1700 the principal questions at issue were the refusal of the settlers to subscribe to the numerous editions of the fundamental constitutions and disputes over the collection of quit rents. Concessions were finally made which brought the government more directly under popular control. In 1693 the commons house, elected by the people, secured the privilege of initiating legislation. The truce was followed by a controversy between churchmen and dissenters. A test act requiring members of the assembly to conform to the Church of England and to take the sacrament of the Eucharist according to the rites and usages of that church (1704) was defeated only through the intervention of the Whig house of lords in England. By an act of Nov. 30, 1706, which remained in force until 1778, the Church of England was made the established religion. After a few years of peace and prosperity, the proprietors, acting on the advice of Chief Justice Nicholas Trott (1663-1740), adopted a reactionary policy, vetoed several popular laws and could not give aid in the desperate 1715 Indian war. In 1719 the people rebelled, overthrew the existing government and elected their leader, James Moore, governor. The result of the revolution was accepted in England, and the province at once came under royal control, although the rights of the proprietors were not extinguished by purchase until 1729. Theoretically South Carolina and North Carolina constituted a single province, but, as the settlements were far apart, their governments were always separate. Until 1691 each had its own governor. From 1691 to 1712 there was usually a governor at Charleston and a deputy for the northern settlements, and after 1712 there were again separate governors. The first attempt to define the boundary was made in 1730, but the work was not completed until 1815.

The period 1725-75 was a period of great prosperity, based upon the trade in pelts (mainly deer skins) and more permanently on the rapidly expanding rice and indigo culture. The southern colonies' Indian trade centred mainly in Charleston. This, and a rich agriculture and the large commercial business to serve them, supplied the economic basis of a coast country society of notable intelligence and culture. One of the earliest theatres in America, musical culture, libraries and the education of a large number of youths in England gave the society around Charleston a tone and finish at that time rare in the new world.

Passing under the royal government did not check the encroachments upon the governor and council by the commons house of assembly, which defiantly announced the powers of the British commons as its model. By 1760 the council had almost ceased to exercise any real control over legislation. It rarely initiated or

amended a bill and never attempted to change a money bill without incurring violent denunciation from the popular house and paralyzing legislative action, once for years.

The province was unconsciously preparing for independence. Though measures of the British government after 1763 were not especially oppressive to the province, the people were too long accustomed to having their own way, and had, especially in the bitter dispute over the Wilkes fund (1769–75) involving the right of the commons alone to control finance, developed too fully a sense of general American and even British freedom to submit to measures which they regarded as subversive of the principles of liberty. Delegates were sent to the Stamp Act congress (1765) and to the continental congresses (1774 and 1775). A council of safety appointed by an extralegal provincial congress virtually took over the government in June 1775. Royal administration ended when, on Sept. 15, the governor dissolved the assembly and field.

Wars with the Spanish in 1686, 1702-04 and 1740, with the Spanish and French in 1706, with pirates in 1718, with the Yemassee Indians in 1715 and the Cherokees in 1760-61, with aid only in 1760-61 from British troops, and a slave rising in 1739 had accustomed the people to arms. The state suffered severely during the Revolution both from British troops and from the presence of numerous loyalists. A British fleet attempting to capture Charleston was repulsed by Fort Moultrie, June 28, 1776. Calm prevailed until Gen. Sir Henry Clinton returned in 1780 with an overwhelming force and Gen. Benjamin Lincoln surrendered the city May 12.

Completely overrun, there followed two years of fighting involving more battles, though most of them small, than occurred in any other state. A continental army under Gen. Nathanael Greene, assisted by state troops under Thomas Sumter, Francis Marion and Andrew Pickens, slowly drove the British back into Charleston and wrecked the plan of British troops from the south to join those from the north to crush Washington. The chief battles fought in the state were Fort Moultrie (June 28, 1776), the siege of Charleston (March 12-May 12, 1780), Camden (Aug. 16, 1780), King's mountain (Oct. 7, 1780, Cowpens (Jan. 17, 1781), Hobkirk's hill (April 25, 1781) and Eutaw Springs (Sept. 8, 1781).

The generation following the Revolution witnessed an ambitious program of transportation development. The Santee canal, connecting Charleston with the whole Santee-Waterce-Broad-Saluda river system, was opened in 1800. Highway building followed. The latter was dropped and the canal was ruined by railroad development. The South Carolina railroad, 133 mi. from Charleston to Hamburg opposite Augusta, when completed in 1833 was the longest railroad in the world.

The early state period was characterized by a bitter struggle between the older low country and the newer upcountry, the latter settled largely by Scotch-Irish coming down the Piedmont belt from Pennsylvania, Virginia and North Carolina. In 1786 it was necessary, to allay discontent, to consent to the removal of the capital to a newly located site to be called Columbia. Although removal took place in 1790, state officers until 1865 kept offices both in Columbia and Charleston and the supreme court met in each city to hear appeals from the two sections respectively. The upcountry (then comprising a larger area than now thus designated), containing four-fifths of the white population and one-fifth of the wealth, in 1808, with the help of a liberal low country minority led by Joseph Alston, secured a constitutional amendment apportioning one senator to each county and representatives to each county in proportion equally to white population and wealth. This left the control of the upper house to the low country and that of the lower house to the upcountry. Manhood suffrage followed in 1810. The low country's fear for its slave interests was allayed as slavery, fostered by cotton culture, spread up the state.

The South Carolina college was chartered in 1801 largely to allay sectional enmity. Only the necessity of standing unitedly against antislavery and reconstruction agitation from the north prevented the more numerous element from forcing its democratic changes until late in the 10th century.

Northern antislayery agitation and the adoption of a tariff harm-

ful to southern agriculture united both sections in the passage of and South Carolina were the only states voting against the repeal the ordinance of nullification, Nov. 24, 1832, forbidding the execution of the tariff in South Carolina. The readiness of a powerful minority to assist President Jackson, combined with a reduction of the tariff, operated to deter the majority from forcing the issue to armed conflict, but left a bitterness within the state that disappeared only toward 1850 in the face of graver danger from outside.

Following the slave conspiracy of 1822 and northern abolitionism the slave code was severely revised (1840-44), even to forbidding the sending of a slave to freedom anywhere in the world. The years 1850-52 saw most of the people deterred from secession only from lack of the co-operation of other states. After 1828 Virginia's southern leadership was superseded by the more uncompromising leadership of South Carolina under John C. Calhoun. South Carolina was the first state to secede, its ordinance of Dec. 20, 1860, being almost unanimously approved by With a white population of 291,300, the state put into the field 62,838 effectives, with a total enrolment, including reserves, of 71,083, of whom 22% were killed or died in prison Gen. W. T. Sherman's march across the state. February to March 1865, was accompanied by enormous destruction, including the burning of Columbia.

The misfortunes of war were more easily borne than the humiliation of reconstruction. Under President Johnson's guidance, the white population elected officers who were soon ejected under the congressional plan of reconstruction, disfranchising many whites and transferring power to the Negroes, northern adventurers ("carpetbaggers") and native whites ("scalawags") joining them. In the spring of 1868 the state was "readmitted" to the union under the control of these elements, and entered upon a period of eight years of crime and corruption, accompanied by arrogance on the part of the Negroes that the whites found galling. Much legislation was by bribery. Stealing extended from large blocks of state property to the price of a politician's whisky. Two hundred trial justices were said to be unable to read. Daniel H. Chamberlain. able carpetbagger and would-be reformer of his own party (governor 1874-76), declared in 1901 that if he had been re-elected in 1876 his party, even with white assistance, could not have given government "fit to be endured." The most urgent pleas on a nonpartisan basis failing to draw the least sympathy in Washington, the whites in 1876, by combined fraud, intimidation and persuasion of Negroes, elected Gen. Wade Hampton (1818-1002) governor by a narrow majority. President Hayes's withdrawal of troops in March 1877 marked the collapse of "radical" rule.

In 1878-80, under the leadership of M. W. Gary (1831-81), the old conflict between uncountry and low country became a fight mainly between the poorer masses and the propertied classes.

The triumph under Benjamin R. Tillman (governor 1890-94; U.S. senator 1895 to his death in 1918), prominent "farmers' movement" leader, was facilitated by acute agricultural distress. Col. A. C. Haskell's appeal to the Negro against Tillman, with proviso that there should be only white officials, was generally condemned even by his own class, drew almost no Negroes and served only to embitter feeling among the whites. The farmers', or more broadly "reform," movement was marked by the establishment of Clemson Agricultural and Mechanical college (1889), the dispensary system of state liquor monopoly (abandoned because of corruption and failure to restrain intemperance) and the work of the constitutional convention of 1895 disfranchising so far as possible the Negro. Direct primary elections, long in use in most of the counties, beginning in some in 1878, were adopted in 1896 for naming U.S. senators, governor and state officers. State politics after 1890 presented a strange combination of rancorous personal politics, mass conservatism and dislike for "aristocratic" influence. Class feeling was strongly manifested in the campaigns of Coleman L. Blease (governor 1911-15). R. I. Manning's administrations (1915-19) were notable for progressive legislation. Factionalism subsiding, Blease was in 1924 elected senator, after having been badly defeated in 1918 on a platform condemning U.S. participation in World War I.

Agriculture and banking suffered severely in the deflation of 1920-21, and all business still more from 1929 to 1937. North

of national prohibition in 1933. In 1935 Gov. O. D. Johnston climaxed his long hostility to the highway department and its chief commissioner, Ben M. Sawyer, by military seizure of the department until condemned by both legislature and supreme court. Public esteem for the construction by the department seemed justified by the failure to discover any wrong. Extensive violent strikes in 1935-36 caused a conservative reaction. President Roosevelt's attempt to defeat Sen. E. D. Smith resulted in Smith's overwhelming re-election, 1938, although the state supported Roosevelt's general policies.

From 1876 almost the entire white population was Democratic, partly from historical reasons and partly because of the conviction that union under the only national party that had defended them against Negro rule in the past was necessary for the maintenance of white supremacy. Only in 1948 did the state bolt the Democratic party, casting its eight electoral votes for Gov. J. Strom Thurmond, of the dissident States' Rights party.

Population .- The population of South Carolina in 1790 was 249,073; in 1840 it was 594,398; in 1880, 995,577; in 1910, 1,515,-400; in 1940, 1,899,804; and in 1950, 2,117,027. This last figure represents an increase of 11.4% over the population in 1940. The population per square mile in 1950 was 69.9, as compared with 62.1 in 1940 and with 50.7 for the U.S in 1950.

Of the 1950 population, 609,225 or 28 8% lived in incorporated places of 2,500 or more, as compared with 24.5% in 1940, when these places constituted the urban area. The entire urban population, under a new definition set up for 1950, which included also the thickly settled suburban area, or "urban fringe," adjacent to the city of Columbia, and 22 unincorporated places of 2,500 or more outside this fringe, amounted to 777,921, or 36.7% of the state total

The number of households in 1950 was 514,660, as compared with 434,968 in 1940.

The average population per household had declined from 4.4 in 1040 to 4.1 in 1050.

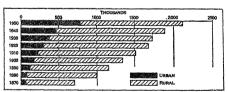

The population of the state was distributed by colour and nativ-

Table I .- Population of South Carolina and Its Principal Cities

<sup>\*</sup>Final figures for 1950 based on new definition. See comment in text.

ity in 1950 as follows: 60.7% native white; 0.4% foreign-born white; and 38.9% nonwhite, practically all Negro. There were 99.1 males per 100 females in the native white population and 93.0 in the Negro population; 5.4% of the population was 65 years old or over; and 56.2% of the population 14 years old and over was in the labour force.

BY COURFREY OF THE U.S. BUREAU OF THE CENSUS

URBAN AND RURAL POPULATION OF SOUTH CAROLINA: 1870 TO 1950 The crosshatched part of the 1950 bar represents the population of the additional areas counted as urban under the new 1950 definition

Of the total number of employed males, 31.1% were engaged in agriculture, 7.9% in construction, 27.7% in manufacturing and 17.3% in transportation and trade,

Government.—South Carolina was governed from 1670 to 1719 under the provincial charter of 1665, from 1719 to 1775 under commissions and instructions from the crown, and from 1776 under constitutions of 1776, 1778, 1790, 1865, 1868 and 1895. An amendment to the constitution may be proposed in either house of the legislature. If approved by two-thirds of the members elected to each it must be submitted to the people at the next election for members of the house of representatives. If it is approved by a majority of those voting upon it and subsequently by a majority vote in each house of the general assembly chosen at that election, it becomes a part of the constitution. A convention to revise the constitution may be called by a two-thirds vote in each house ratified by a majority of those voting for representatives at the next election.

A voter must be 21 years old, a resident of the state two years, of the county one year and of the voting precinct four months and must obtain a certificate of registration conditioned on showing that he or she is able to read and write the constitution or the past year paid taxes on property assessed at \$300 or more. (Assessments are usually at about one-fourth value.) Paupers, idiots, the insane, prisoners and persons ever convicted of certain crimes, unless bardoned, are disfranchised.

The Democratic nonvnation is equivalent to election. Voting in the Democratic primary was confined to whites without other qualification than age and residence until federal courts in 1948 ordered Negroes admitted to party membership (few joined immediately). Qualifications became the same as for the general election.

Constitutional amendments changed the terms of the governor and other state officers from two to four years, beginning with those elected in 1926. The governor is ineligible for immediate re-election. He may veto "any one or more of the items or sections contained in any bill," but may be overruled by a two-thirds majority of those voting in each house. In practice the item veto has been used only for appropriation bills. The governor cannot grant pardons except on the recommendation of the pardon board, but he may reduce a death sentence to life imprisonment.

The general assembly, meeting annually, is composed of the senate (one member from each of the 46 counties elected for four years) and the house of representatives (124 members elected for two years from the counties in proportion to population). The state elects six congressmen.

The 5 supreme court judges and the 14 circuit court judges are elected by the legislature for ten and four years respectively. Magistrates (justices of the peace) are appointed by the governor with senate confirmation, although the recommendation of the senator from the county or of the primary election practically determines the selection.

In a few counties a county court with an elected judge disposes of a large part of the lesser civil and criminal cases elsewhere burdening the circuit courts. The probate judge in each county (elected) has also the duties of a juvenile court. The state is divided into two federal court districts.

Local Government.—The unit of local government is the county. Counties are divided into townships, which have no governments and exist largely for the assessment of taxes and the care of local roads. Although the forms of municipal government are prescribed under general statutes and enjoy certain constitutional rights, they are considerably subject to state legislative authority. They may exempt new industries from taxes for five years, except for school purposes, provided a majority in a popular election approves.

The county is administered by a commission, almost always popularly elected. Road or hospital commissions, etc., are frequently appointed by the governor, usually on recommendation of the county legislative delegation. Most of the county officers are elected, except the auditor and treasurer, who are appointed by the governor with senate confirmation; however, the governor almost always names the successful primary election candidates

without question. Since only Charleston has a county council the state legislature is oppressed with a mass of local legislation. It enacts usually without question whatever the senator and representatives of the county concerned agree upon. The latter thus form in effect a county legislature. The senator, by controlling action in the senate, exercises an enormous extralegal power.

Miscellaneous Laws.—Any officer negligently permitting a more to be lynched forfeits his office and becomes ineligible to any office unless pardoned. The county, without regard to the conduct of the officers, is liable to damages of not less than \$2,000 to the heirs of the deceased. In 1949 divorce became allowed for adultery, drunkenness, physical cruelty or desertion.

Finances.—The state tax commission, created in 1915, supervises all tax administration and directly administrates those taxes from which most of the state revenue is derived, such as taxes on incomes, gasoline, retail sales, drinks, electric power, corporations and business. There exists in practice a considerable control of state and local tax sources, the local governments depending mainly on the general property tax; however, the counties receive a share of state gasoline and income taxes, and both county and municipality share the state tax on beverages. The state debt, mainly for roads, on June 30, 1950, was \$68,995,598. The general appropriations bill for the year ending June 30, 1951, totalled \$108,538,717.

Education .- As early as 1710 public-school education was provided for indigent children. The modern free school system was established in 1868. The educational system is under the supervision of a state superintendent of education, with the assistance of a board composed of the governor, the superintendent of education and seven other persons appointed by the governor. State support and regulation of high schools were greatly increased in 1907. South Carolina maintains a dual school system: one for white and one for Negro children. Enrolment in the public elementary schools for the year 1949-50 was 377,356, of whom 190,-465 were white and 186,891 Negro; in the high schools there were 116,829, including 81,840 white and 34,989 Negro. There are adult night schools, enlarged facilities for agricultural, vocational and home economics training, state standard certification of teachers and effective state supervision. By the 1919 law, four months' school attendance became compulsory, but enforcement remained lax despite improvement after 1937.

Agriculture.—South Carolina's farm products are normally valued at much less than its factory output. Thus in 1950, when the gross income from agriculture for the state was \$284,780,000, the value of manufactures was \$1,708,383,629. A notable change in the period 1930–50 was the great increase in the production of peaches. In several years the crop was second only to that of California.

The total farm acreage in 1940 was 11,238,697, or 57.4% of the whole area of the state, a slight increase over the figures for 1930, which were, respectively, 10,39,300 and 53.3%. The total harvested acreage in 1950 was 4,097,000, being 13% below the average for the period 1939-48. Of the 137,558 farmers in 1940, more than half, or 76,251, were white. White owners were 42,783, Negro 17,084; white tenants were 32,990, Negro 44,194; white managers were 478, Negro 29. The percentage of tenancy was 56.1.

The valuation of all farm land and buildings in 1940 was \$338,-494,517; of the average farm, \$2,461. The average value per acre of land alone was \$30.12. The farm population decreased during the ten-year period 1930-40 only slightly, from 914,098 to 913,312. Cotton, though no longer heading the list in acreage, still held

TABLE II .- Principal Crops of South Carolina, 1950

Crop				Acreage	Product	Value
Cotton (bales) Cottonseed (tons) Tobacco (lb) Corn (bu.) Cost (bu.) Hay (tons) Sweet potatoes (bu.) Wheat (bu) Peanuts (lb.) Cowpeas (bu.)	:	:	:	870,000 870,000 114,000 1,446,000 678,000 422,000 156,000 21,000 65,000	400,000 162,000 150,480,000 33,258,000 18,984,000 3,44,000 5,671,000 2,184,000 15,750,000 3,58,000	\$79,800,000 12,442,000 82,463,000 46,551,000 17,086,000 10,064,000 9,641,000 4,805,000 1,922,000 1,700,000

first place in total crop value at mid-20th century. The state has two great cash crops, cotton and tobacco; five grain crops, corn, wheat, oats, rye and barley; four legumes that yield both hay and grain, cowpeas, soybeans, velvet beans and peanuts; two for syrup, sorghum and sugar cane. Potatoes, both white and sweet, fruit and vegetables also add to the wealth of the state.

The coastal region, with a mild climate and a soil responding quickly to intensive cultivation, is especially suited to commercial truck farming. The chief products, exclusive of potatoes and cane grown for syrup, are watermelons, cabbages, cucumbers, snap beans, beets, asparagus, tomatoes and lettuce. Strawberries, dewberries, blackberries, figs and grapes add to the fruit wealth

Dairying and the livestock industry as a whole were capable of much further development at mid-century. The state produced only about one-third of the creamery butter it consumed, there being little more than one cow to the farm on an average. In 1950 there were reported 172,000 milch cows in the state; in 1949 the total milk production was 615,000,000 lb. The total value of the principal classes of livestock was \$77,047,000.

Forests and Fisheries.-The total stand of saw timber on South Carolina commercial forest land in 1947 was estimated at 25,696,200,000 bd.ft., of which 14,991,400,000 bd.ft. were in softwoods and 10,704,800,000 bd ft. in hardwoods. The annual growth was estimated at 1,457,100,000 bd.ft. In 1946 lumber production in the state was 1,520,198,000 bd.ft., or about 2.5% of the nation's total. Small quantities of turpentine and rosin are produced from the slash pine forests of the coastal plain.

The commercial fisheries are located in the five coastal counties -Beaufort, Colleton, Charleston, Georgetown and Horry. Oysters are canned in quantity, but several other kinds of fish are

also taken.

Minerals.—South Carolina's mining output is small, amounting in 1950 to less than .01% of the total mineral value of the United States. The principal mineral products were clay products, stone, sand and gravel. The stone quarried is chiefly granite and granite-gneiss. High-grade granite, the "Winnsboro Blue," is quarried in Fairfield county near Rion.

Manufactures.-In 1949 there were 1,783 manufacturing establishments in South Carolina, employing 173,926 wage earners and producing \$1,701,839,000 worth of goods. Activity had somewhat recovered from the depression by 1933, was nearly normal by 1940 and increased substantially during World War II and after. Of the total value of product, cotton goods constituted about 70%. The number of textile manufacturing plants in 1949 was 278, the number of producing spindles 5,741,916 and the number of operatives 124,379. The amount of raw cotton consumed was 1,799,404 bales, and the value of the output was \$1,175,337,-135. Almost every grade of cotton cloth is produced. Factors contributing to the rapid development of the cotton textile industry in South Carolina were the abundance of cheap hydroelectric power from the numerous streams, a suitable climate and dependable native labour. The Piedmont section led in the textile industry. The values of the output in 1949 for the chief producing counties were as follows: Greenville, \$221,429,249; Spartanburg, \$219,112,346; Anderson, \$201,571,602; York, \$79,724,-489; and Greenwood, \$73,552,669. Laurens, Lancaster and Chester are also large manufacturers of textiles. Charleston and Richland counties are important for diversified industry.

During 1949 paper and pulp were valued at \$77,679,802; clothing, \$62,760; electric current, \$42,594,385; fertilizers, \$35,921,-923; meat packing and abattoirs, \$26,813,226; barrels, boxes, baskets and veneering, \$25,013,178; cottonseed oil, meal and cake, \$22,985,863; foundry and machine shops, \$19,469,471.

Hydroelectric development greatly aided industry and improved living conditions. Of the numberous hydroelectric installations the greatest is the publicly owned Santee-Cooper project. Its two reservoirs (Lakes Marion and Moultrie) have a combined area of 160,000 ac. and develop approximately 133,000 kw. Lake Murray dam, about 10 mi, above Columbia on the Saluda river, 208 ft. high and 7,000 ft. long (one of the largest -earth dams), forms a lake about 50,000 ac. in area and develops

130,000 kw. The state's total hydroelectric capacity in 1950 was about 673,000 kw. The average residential consumer in 1948 was using about three times as much electricity as in 1932. On June 30 1948, 27,460 mi. of rural electric lines were serving 152,-275 customers.

Transportation and Commerce.-The chief railway systems of South Carolina are the Southern, the Atlantic Coast Line and the Seaboard Air Line. Steam railway mileage was gradually reduced from 3,780 mi. on Dec. 31, 1930, to 3,563 mi. in 1950, not including second tracks or sidings. During the same period there was a steady increase in the mileage of paved roads built by the state government. The mileage of state highways on June 30, 1950, was 21,036, of which 12,083 mi. were hard-surfaced. Mileage under county systems was 27,376. Automobile registration was 231,274 in 1929, 324,290 in 1940 and 571,840 in 1950.

Inland water communication is possible on a number of the larger navigable rivers, but is not greatly developed. South Carolina in the year ending June 30, 1950, carried on foreign trade to the value of \$94,200,000, of which \$34,600,000 represented imports and \$59,600,000 exports. Duties collected totalled \$2,522,-

050. Coastwise tonnage is greater than foreign.

o50. Coastwise tonnage is greater than foreign.

U.S., on the south bank of the Kanawha river, 4 mi. W. of Charleston. It is on U.S. highway 60 and is served by the Chesapeake and

The population was 16,686 in 1950 and 10,377 in 1940 by the federal census. South Charleston is a chemical manufacturing centre; its plants produce alcohols, resins, ethers, acids and chlorinated hydrocarbons. Antifreeze liquids, thermoplastics and dentures are also manufactured there.

Under a mayor-council form of government the city's mayor and eight councilmen are directly elected for terms of four years. The South Charleston seaplane base is located on the south bank of the Kanawha river 1 mi. W. of South Charleston. Facilities at the base include mooring equipment, floats, a marine railway and hangar.

Hospitals in South Charleston are the Dunn hospital, established in 1915, the Kanawha Valley Medical centre, established in 1944, and the Herbert J. Thomas Memorial hospital, established in 1946.

There is a conical Indian burial mound 175 ft. in circumference at the base and 30 ft. high in Staunton park, a triangular park near the western end of the city. The federal government opened the mound in 1883 and found ornaments, stone weapons, fragments of pottery and a number of human skeletons.

SOUTHCOTT, JOANNA (1750-1814), English religious fanatic, was born at Gittisham in Devonshire. Her father was a farmer and she herself was for a considerable time a domestic servant. She was originally a Methodist, but about 1792, becoming persuaded that she possessed supernatural gifts, she wrote and dictated prophecies in rhyme, and then announced herself as the woman spoken of in Revelation xii. Coming to London at the request of William Sharp (1749-1824), the engraver, she began to "seal" the 144,000 elect at a charge varying from 12s. to a guinea.

When over 60 she affirmed that she would be delivered of Shiloh on Oct. 19, 1814, but Shiloh failed to appear, and it was given out that she was in a trance. She died of brain disease on Oct. 29, 1814. Her followers are said to have numbered more

than 100,000, and are not yet extinct.

Among her 60 publications, all equally incoherent in thought and grammar, may be mentioned: Strange Effects of Faith (1801-02); Free Exposition of the Bible (1804); The Book of Wonders (1813-14); and Prophecies Announcing the Birth of the Prince of Peace (1814).

A lady named Essam left large sums of money for printing the Sacred Writings of Joanna Southcott.

See D. Roberts, Observations on the Divine Mission of Joanna Southcott (1807); R. Reece, Correct Statement of the Circumstances attending the Death of Joanna Southcott (1815).

SOUTH DAKOTA, the "Coyote" or "Sunshine" state, is one of the north-central states of the United States. It is about 380 mi. (east-west) by 200 mi., with an area of 77,047 84,mi., of which 511 sq.mi. are covered by rivers or lakes. Its extreme points are approximately 42° 29′ and 45° 57′ N. and 96° 26′ and 104° 3′ W. It is a state of great variety of natural features and of production. Dakota territory, named for the Dakota or Sioux Indians, originally also included Montana and Wyoming, but when North and South Dakota, the only twin states in the union (simultaneously created), were admitted on Nov. 2, 1889, the territory so divided consisted of the states as they now exist.

Physiography.—The eastern part of the state to the Missouri river, which originally flowed in the valley of the modern James river, was covered by the advancing great glacier and is largely flat prairie. In the northeastern section are many lakes lying in the glacier-created hills known as Coteaus. The James river has scant fall across the state. The Missouri river, formed by the glacier, is, down to the mouth of the James river, a deep narrow river plain, being seldom more than 2 mi. in width and often

ROCK NEEDLES IN BLACK HILLS, SOUTH DAKOTA

constricted to a river plain less than I mi. wide. East of the Missouri there is little wasteland; most of the land is tillable and with sufficient moisture. West of the Missouri the land is largely rolling grassland, cut by a number of streams of considerable size. chief of which are the Grand, Moreau, Cheyenne, Bad and White rivers. South of the White river the soil is sandy and most of the creeks flow water at all times. On either side of the White river, and particularly north of it, in the area between it and the South Fork of the Cheyenne, is an area known as the Bad Lands, the Mauvaises Terres of the early French. This area is prolific in fossil finds. The ground forms are grotesque and picturesque and interspersed therein are numerous well-grassed flat-topped tablelands. The Black hills are in fact mountains, the highest of which. Harney Peak (7,240 ft.), is the highest point in the United States east of the Rocky mountains. This great upthrust stands out from a surrounding prairie region. Its granite-topped peaks are verdure-clad nearly to their summits and, combined with pine forests, mountain streams and a large number of man-made lakes, create a picturesque and pleasing prospect. The Rushmore National memorial is located near the centre of this area, adjacent to the South Dakota State park, largest state park in the nation. There are several large caves in the Black hills, the largest and most beautiful being Wind cave, a national memorial in the southern hills, and Crystal cave, north of Rapid City. North from the Black hills are the Cave hills and the Slim buttes, great masses of land rising from surrounding prairies. The Slim buttes are particularly weird and beautiful.

With the exception of a small area in the extreme northeastern part of the state adjacent to Lake Traverse, the entire state is drained to the Missouri river by north-and-south streams, the Sioux, Vermilion and James rivers east of the Missouri, and, in the west river area, by the east-and-west rivers named above. There are a large number of lakes in the northeastern area and on the high ground between the Sioux and James rivers.

The woodland area of South Dakota is almost exclusively in the Black hills, consisting of an estimated 2,500 sq.mi. &f 3.25% of the entire land area. Except for tree claims (1870–90) planted east of the James river, other woodlands are found only surrounding lakes or along streams. There is a wide diversity of trees including the elm, oak, box elder, cottonwood and hackberry native in the eastern section, and the ponderosa pine, spruce, aspen, white birch and cedar native to the Black hills. Small cedars are found in much of the rough country west of the Missouri, particularly along the White and Little White rivers. There are three national forests in the Black hills, the Harney, Custer and Black Hills forests, composing in all more than 1,000,000 ac.

Climate.—There is considerable variety in the climate because of the state's distance from great bodies of water and its rather large variation of altitude (from 1,000 to 6,000 ft. above sea level). Rainfall varies, except in the Black hills area where it compares with that of the southeastern section, from the southeast across the state to the northwest. Yankton (28.15 in.), Pierre (16.11 in.) and Camp Crook (13.89 in.) have typical averages. The growing season is limited by the periods between frosts-110 to 120 days in the northern part of the state and 140 to 160 days in the south and southeastern portions. Winters vary greatly, some including from 90 to 150 days of cold and snow and many having little snow. Temperatures vary from an average of 42° in the northeast to 48° in the southwest. Summer temperatures frequently reach 110° but because of the dryness are not oppressive, and the nights ordinarily are cool. There are recurrent years of drought with none very extensive except in the 1930s, when seven of the ten years were extremely dry.

History.—Archaeologists discovered from the contents of mounds and village sites a people who lived in the area prior to the Aricara Indians, whose history antedates A.D. 1500. White men knew considerable about South Dakota prior to 1700, if not by actual penetration into the area. The first certain penetration was made in 1742 by the Vérendrye brothers, who came into northwestern South Dakota via the Mandan villages of North Dakota and who on March 30, 1743, planted a leaden plate at Fort Pierre where they gave up their search for a western sea.

In 1780 or thereabouts Pierre Dorion settled near Yankton and during the next two decades many traders arrived. Some, notably Jacques d'Eglise, crossed the state on the Missouri to trade with the Mandans. The first building certainly constructed by white men in South Dakota was by Jean Baptiste Truteau, on the river to mi. S. of Lake Andes in 1794. John Valle had been near to if not to the Black hills prior to 1804 and traders from the upper Mississippi had been in the northeastern part of the state. That year Meriwether Lewis and William Clark ascended the river on their notable trip to the Pacific. France first claimed the area. then in 1762 secretly deeded it to Spain, which returned it to Napoleon; the latter sold it to the United States in 1803. The Lewis and Clark report was so glowing that the area promptly became a mecca for the fur seekers, Manuel Lisa, Pierre Choteau, Registre Loisel and many others, who sought to open posts in the area. The War of 1812 seriously impeded trade but by 1817 Teach LaFramboise had started a post at Fort Pierre, the site of the first permanent settlement in the state. The fur trade prospered greatly In 1823 the Aricara Indians barred the ascent of the Missouri to traders and a bloody battle ensued When this was reported to Col. Henry Leavenworth at Fort Atkinson 600 mi. downstream, he led a small group of U.S. soldiers and a motley array of trappers and traders with some highly uncertain Indian allies up the Missouri in record time to the mouth of Grand river, where he broke the power of the Aricaras. Fort Pierre was the fur capital of a trade territory of 250,000 sq.mi. In 1831 the first steamboat, the "Yellowstone," mounted the Missouri to that point and the steamboat, with its ease of travel and transport was mainly responsible for the decimation of the buffalo, which by 1855 no longer roamed in countless numbers. Fort Pierre was then sold to the government as a military post.

No attempt at settlement by other than traders was made until 1856 when pioneers from Iowa and Minnesota, drawn by the power prospects at the falls of the Sioux river, located there and at Medary farther north. These settlements persisted until the War of the Indian Outbreak in 1862. Meanwhile some settlers were moving into the bottoms of the Missouri adjacent to the present Sioux City and a permanent settlement was effected at Yankton in 1859. In 1862, when Dakota became a territory, Yankton was made its capital. In the next decade, however, only 11,915 people had made the area their home; the settlements were largely on the Missouri and its tributaries, the Sioux, Vermilion and James rivers. The railroad from Sioux City to Yankton was completed in 1872, to Sioux Falls in 1878 and to Watertown in 1873 (abandoned, but again completed in 1878). The discovery of gold in the Black hills in Aug. 1874 by Gen. George A. Custer had started a great inrush into that area, which provoked the Indian activities of 1876 culminating in the Custer massacre in Montana. The first gold was discovered in French creek near Custer, which in the winter of 1875-76 boomed to a town of 6,000. But the deposits there played out and a rush to the discoveries at Deadwood began. In the Deadwood area the deposits were of greater value. The Dakota boom of the 1880s was soon in progress. There were 327.21 mi. of railway prior to 1880. In the next decade 1,800.65 mi. had been added, and the population had more than tripled to 328,808. Free homesteads were to be had for the occupancy and "tree claims" could be planted and added to the free land available. The area east of the Missouri and the Black hills was pretty well settled by 1800.

In 1883 and again in 1885 constitutional conventions met. Finally in July 1889 an omnibus bill was passed, granting statehood to the two Dakotas, Wyoming, Idaho, Montana and Washington. The Dakotas qualified first, and Pres. Benjamin Harrison signed the proclamations and published them simultaneously, the only "twin" states in the union, as of Nov. 2, 1889. The advent of the new states was inauspicious; 1889 and the following eight years saw much drought; many homesteaders went bankrupt and left the area. In the first five years the population was static, a gain of only 2,167 being recorded until 1895. Better rainfall, a political change and a war boom raised the state population to 401,570 by 1900. The early settlement had largely been by people of native stock, but in the 1870s and 1880s large numbers of north-

ern Europeans came into the country, staying for the most part during the depression of the 1890s. The country west of the Missouri except for the Black hills area was largely Indian reservation. The area between the White and Cheyenne rivers and west of Pierre to Rapid City had been opened in 1889 but with very few homesteaders. By 1903 there was a movement into that area. Meanwhile the effort to open the reservations to settlement persisted; in 1905 the eastern Rosebud was opened, and in 1909 the areas in Tripp and Mellette counties in the Rosebud and in Dewey, Corson and Ziebach counties in the Rosebud and Standing Rock reservations were opened. Railroads were built into the areas and general prosperity resulted in a large population increase, to 583,888 by 1910.

South Dakota had been created by a strongly Republican congress elected in 1888 and for its first 25 years was a Republican state with the exception of the years 1897 to 1901 when a Democratic administration, the result of the Populist movement of the 1890s, came into power. The state suffered three periods of depression and drought: the early 1890s, the years 1910-12 and 1931-39. In the election of 1906 the Republican party was split into two groups, the Standpatters and the Progressives, who were successful for a long time. This faction was responsible for the constitutional amendments that permitted the state to enter into a variety of business affairs, including rural credits, state bonding, state coal mining, state hail insurance, state cement plant and state guarantee of bank deposits. These various projects involved the state in about \$60,000,000 of indebtedness. With the exception of the state cement plant, all had been liquidated by mid-20th century and the indebtedness largely paid off. Some financial scandals growing out of these business affairs resulted in the election of a Democratic administration in 1927. The Standpat faction of the Republican party elected a governor in 1931, but the commencement of the drought and the low prices of 1032 ousted him for a Democratic administration from 1033 to 1937, after which date the state was solidly Republican and antisocialistic. World War I and the postwar prosperity of 1919-20, together with unjustifiably high land and cattle prices, saddled the farmers with debt, and the deflation of the early 1920s resulted in liquidation of many banks and the elimination of the state bank guaranty fund. High farm prices created by World War II and bumper crops placed the financial affairs of the state and its citizens in a favourable condition in 1950.

Government.-The state constitution adopted on admission to statehood in 1889 has been amended many times. The state legislature, consisting of a senate of 35 and a house of 75 members, makes laws subject to the people's right to refer its laws and to initiate laws of their choosing: South Dakota was the first state to adopt such measures (1808). Either can be invoked by a petition of 5% of the voters. All state officers are elected for two years. The governor has the usual right of veto, except for initiated measures; the veto can be overridden by a two-thirds vote. He has the customary power to pardon and reprieve. The courts consist of a supreme court, 12 circuit courts, county courts and municipal and justice courts. Supreme court judges are chosen from given districts for six-year terms, circuit judges serve for four years and all others for two years or as may be fixed by municipal ordinance. In 1950 there were 20 circuit judges for the 12 circuits.

Population.—The area which now forms South Dakota had 11,776 inhabitants in 1870 and 348,600 in 1890. The population of the state in 1910 was 583,888; in 1940, 642,961; and in 1930, 652,740. This last figure represented an increase of 1.5% over the population in 1940. The population per square mile in 1950 was 8.5, as compared with 8.4 in 1940 and with 50.7 for the U.S. in 1950.

Of the 1950 population, 216,151, or 33.1%, lived in incorporated places of 2,500 or more, as compared with 24.6% in 1940. South Dakota had neither cities of 50,000 or more nor unincorporated places of 2,500 or more, but its urban area in 1950 included a part of the urban fringe of Sioux City, Ia., making a total of 216,710, or 33.2% of the total. The population of the state and its principal cities is summarized for recent censuses in the table,

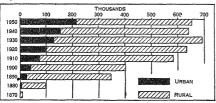

The number of occupied dwelling units (or households) in 1950 was approximately 180,000, as compared with 165,000 in 1940.

Area			Population	Per cent of increase		
		1950	1940	1930	1940-20	1930-40

\*Final figures for 1950 based on new definition. See comment in text

The average population per household had declined from 3.9 in 1940 to 3.6 in 1950.

The population of the state was distributed by colour and nativity in 1940 as follows: 89.4% native white; 6.9% foreignborn white; and 3.7% nonwhite, practically all Indians. Of the foreign-born white population 38.1% were born in Scandinavian countries (19.8% in Norway, 9.9% in Sweden and 8.4% in Denmark), 18.9% in Germany and 14.7% in Russia. There were 105.4 males per 100 females in the native white population, and

BY COURTESY OF THE U.S. BUREAU OF THE CENSUS

URBAN AND RURAL POPULATION OF SOUTH DAKOTA: 1870 TO 1950

132.0 in the foreign-born white; 6.8% of the population were 65 years old or over; and 50.3% of the population 14 years old and over were in the labour force. Of the total number of employed males, 57.5% were engaged in agriculture, 3.7% in construction, 48% in manufacturing and 17.7% in transportation and trade.

Education .- The public- and secondary-school system of South Dakota is under the supervision of the state superintendent of education, a constitutional officer. There were on June 15, 1950, 156,372 persons of school age in the state. Of this total, 117,675 were in public elementary and high schools and 10,243 in parochial schools. The total cost of public-school education in 1949-50 was \$25,984,238, or \$221 per pupil. The state's educational institutions with 1950 school enrolments were as follows: University of South Dakota, Vermilion, 1,622; South Dakota State College of Agriculture and Mechanic Arts, Brookings, 1,732; South Dakota School of Mines, Rapid City, 473; Northern State Teachers college, Aberdeen, 643; Southern State Teachers college, Springfield, 177; General Beadle State Teachers college, Madison, 150; Black Hills Teachers college, 412; School for Deaf, Sioux Falls, 89; School for Blind, Gary, 37. There were in addition five privately endowed colleges as follows: Huron college, 289; Yankton college, 290; Dakota Wesleyan university, Mitchell, 281; Augustana college, Sioux Falls, 774; and Sioux Falls college, 243.

Charities and Corrections.—The state maintains a penitentiary at Sioux Falls with a constantly fluctuating number of inmates (46 in 1950); a training school for boys and girls at Plankington (117 in 1950); a hospital for the insane at Yankton (1,732 immates in 1950); and a home for the feeble-minded at Redfield, with about 800 immates.

Finance.—The state originally had a constitutional limitation of indebtedness of \$100,000. By a series of amendments in 1916 and 1918, however, this limitation was removed for specific purposes and in 1920 the gross debt, largely for rural credits, had increased to about \$60,000,000. As of 1950, the debt had been

reduced to \$19,730.994, sinking funds considered. This sum included a balance of \$12,324,520 still due on a \$21,000,000 bond issue of 1949 to pay a veterans' bonus. The state general fund, much of which could be applied on state debt, with legislative sanction, was on Oct. 1, 1950, \$16,915,568. The 1950 total assessed valuation was \$1,320,257,692, of which real estate was 62,43%. Total local and state revenues from all sources in 1949–50 amounted to \$88,182,234,38. Federal taxes paid the same fiscal year amounted to \$57,995,865, op a total burden of taxes and excises of \$146,178,199,45—a per capita burden of \$224,90.

Purely state receipts from all sources were \$59,441,588.88 for the fiscal year 1948-49, of which \$2,010,661.56 came from moneys and credits, maintenance of insane, inheritance taxes and game and fish funds derived from county treasurer receipts; \$38,263,232.29 from motor fuel, sales tax, cigarette stamps, beer tax and licences and similar sources; \$13,534,316.32 from federal aid to highways, state college, health, public instruction, game fish and possible social security and like agencies; \$2,170,223.11 from local endowments and fees, tuitions and sales of endowment lands; \$2,462,955 60 from sales of school and public lands, rentals and interest. Of this sum, \$57,346,940.49 was disbursed for the following purposes educational institutions \$4,464,715.33; motor fuel refund (to farmers for nonhighway purposes) \$3,380,474.31; veterans' bonus \$2,052,321.75; cement plant \$2,638,627.37; highways \$18,777,018.44; appointive offices \$1,595,950; constitutional offices \$779,803.75: penal and charitable institutions \$2,137,687; rural credits (debt) \$2,771,000; social security \$8,416,825.17; common school aid \$3,240,711.05; game-fish parks \$1,260,301.13; buildings and improvements \$902,040.53; all other \$4,928,969.66. Federal aid items amounted to 23.3% of federal taxes paid. National banks as of April 24, 1950, had assets of \$262,120,000, with loans and discounts of \$74,241,000 or 28%; state banks had assets of \$227,241,341.73 and loans and discounts of \$65,748,962.32 or 29%. Total bank assets amounted to \$489,361,341 or \$753 per

Agriculture and Livestock .- The growing of crops and livestock for market is South Dakota's chief resource. The average production for principal crops during 1938-47 was: corn, 79,028,-000 bu.; wheat (all), 37,530,000 bu.; oats, 77,963,000 bu.; barley, 33,186,000 bu.; rye, 6,464,000 bu; flaxseed, 3,069 bu.; buckwheat, 42,000 bu.; potatoes, 2,390,000 bu.; soybeans, 209,300 bu.; sorghum (all), 1,957,000 bu.; hay (all), 2,638,000 tons; alfalfa seed, 29,000 bu.; sweetclover seed, 38,800 bu. Value of production over this decade averaged \$246,315,000 annually. The 1948 production alone amounted to \$485,954,000. Much of South Dakota production is marketed in the form of animals. The 1939-48 averages were as follows: all cattle and calves, 2,176,000, worth \$154,261,000; horses, 314,000, worth \$14,546,000; mules, 4,000, worth \$279,000; hogs and pigs, 1,628,000, worth \$43,038,-000; sheep and lambs, 1,829,000, worth \$16,980,000; chickens, 9,278,000, worth \$8,754,000; turkeys, 206,000, worth \$607,000. This represents an average annual total value of \$238,465,000. The 1949 value of farm animals was \$472,942,000. In 1949 there were 334,000 cows producing 1,369,000 lb. of milk and 52,000,000 lb. of butterfat. There were 8,083,000 hens producing 1,060,000 eggs for a cash income of \$28,586,000; at the same time the gross income from sales of chickens was \$10,647,000 and of turkeys \$1,403,000. In 1949, 715,000 sheep were shorn, producing 5,928-000 lb. of wool valued at \$2,786,000. In the same year 2.286,971 hogs, 892,570 cattle and 579,517 sheep were marketed. The 1949 farm income from all sources was: crops and livestock \$527,389,-000, government payments \$4,241,000; total \$531,630,000.

Manufactures and Mining.—South Dakota has few industries. In 1947, 494 establishments with 8,662 workers added \$51,398,000 in value to materials processed. Food processing plants accounted for 5,359 or 64% of the workers, lumber products 903 and printing and publishing 712. The rest were engaged in the fabrication of machinery, metal products, stone, clay and chemicals.

In 1949 the value of mineral production in South Dakota exceeded \$23,000,000, the chief item being 464,613 oz. of gold with a value of \$16,221,699. The chief source of gold was the giant

Homestake low-grade deep mine situated at Lead. Silver production was 109,150 oz. valued at only \$98,777. The production of other metals was as follows (in tons): iron ore \$1,50; beryl 63; feldspar 37,930; lithium ore \$1,27; mica 944; quartz 32. These totalled \$65,059 in value. Baser production included bentonite 17,81,38 tons, \$1,603,424; brick and tile 17,000 tons, \$60,200; cement 687,331 lb., \$1,787,060; granite 264,469 cu.ft., \$2,150,250; gypsum 7,081 tons; lime 1,513 tons. The production of galena ore was at a standstill because of the low prices of silver and lead. South Dakota annually ranks first or second in gold production. The Homestake mine at mid-20th century had produced more than \$450,000,000 in gold. The Black hills area has deposits of almost every known precious mineral but frequently not in paying quantities. In 1914–18 tungsten to the value of \$1,106,740 was produced.

Transportation.—Railways operating in 1950 had 4,665.27

10.0 Markekage serving 492 communities; 3.972 mi. of track were
main line. There is only one transcontinental railroad, the Chicago, Milwakee, St. Paul and Pacific, operating nearly 1,800 mi.
The Chicago and North Western operates about 1,200 mi. Gross

freight earnings for 1949 were \$27,907,770.

The highways of South Dakota in 1950 included 426.1 mi. of concrete; 3,131.9 mi. of oiled surface; 27,455.6 mi. of gravel; and 62,994.7 mi. of made road. During the fiscal year 1949–50 the state highway commission spent \$16,552,620.87 on road building and maintenance.

SOUTHEND-ON-SEA, a county and parliamentary borough and watering place in Essex Eng. A2 mi, from London

SOUTHEND-ON-SEA, a county and parliamentary borough and watering place in Essex, Eng., 43 mi. from London by road. Pop. (1951) 351,830. Area 16.7 sq.mi. It was visited by Queen Caroline in 1804 and is the nearest seaside resort to London. The bathing is good, but the tide recedes rapidly for nearly a mile. The pier, which is more than 14 mi. in length, permits the approach of steamers at all tides. Westcliff-on-Sea is a favestern suburb. To the westward again is Leigh-on-Sea; its lofty Perpendicular church tower is visible from afar. The castle was built in the 13th century, and two ruined towers remain. Canvey Island, 10 mi. W. of Southend, is a holiday resort. Southend was incorporated in 1892, became a county borough in 1914 and a parliameters because in 1818.

parliamentary borough in 1918. It returns one member.

SOUTHERNE, THOMAS (1660-1746), English dramatist,
was born at Oxmantown, near Dublin, in 1660, and entered Trinity
college in 1676. Two years later he was entered at the Middle
femple, London. His first play, The Persian Prince, or the Loyal
Brother (1682), contained a flattering portrait of James II as the
"loyal brother." The poet received a commission in Princess
Anne's regiment, but his military career came to an end at the
Revolution. He then gave himself up entirely to dramatic writing. In 1692 he revised and completed Cleomenes for John Dryden; and two years later he scored a great success in the sentimental drama of The Ratal Marriage, or the Innocent Adultery
(1694). The piece is based on Aphra Behn's The Nun, with the
addition of a comic underplot. It was frequently revived, and
in 1757 was altered by David Garrick and produced at Drury
Lane. It was known later as Isabella, or the Fatal Marriage.

The general spirit of his comedies is well exemplified by a line from Sir Anthony Love (1691): "Every day a new mistress and a new quarrel." This comedy was his best.

Southerne scored another conspicuous success in Oroonoko, or the Royal Slave (1696). He died on May 22, 1746.

His other plays were The Disappointment, or the Mother in Fashion (1684), founded in part on the Curioso Impertinente in Don Quixote; The Wives' Excuse, or Cuckolds Make Themselves (1692); The Maid's Last Prayer, or Any, Rather Than Fail (1692); The Fate of Capua (1700); The Spartan Dame (1719), 21-D

taken from Plutarch's life of Aegis; and Money the Mistress

SOUTHERN OCEAN. By Southern ocean is understood the oceanic areas from the antarctic continent to about lat. 40° S. This region is often dealt with as an entity because the climatological features, water masses and currents are similar all around the continent. In geography, however, it has been the established practice to consider the Atlantic, Pacific and Indian oceans (qq.v.) as extending to the antarctic continent. (H. U. S.)

SOUTHERN OVERLAND MAIL. In 1850 monthly mail services were established by the federal government from Independence, Mo., to Santa Fe, N.M., and to Salt Lake City, Utah. A one-way trip on each route took approximately 30 days. A similar service was inaugurated in 1851 between Salt Lake City and Sacramento, Calif. There were no stations along the routes, and it was usually necessary to use one team for the entire trip. Since these facilities proved inadequate, most of the mail to the west was sent via Panamá by steamship.

In 1857 the Overland California Mail bill was passed by congress. Provisions of the act set the itinerary of the proposed route from St. Louis, Mo., to Little Rock, Ark., and then through

El Paso, Tex., and Yuma, Ariz., to California.

Under this act, the semiweekly Southern or Butterfield Overland route began in 1858 on a 25-day schedule. The choice of the Southern route was opposed by advocates of a central route through Salt Lake City.

The postmaster held that unfavourable northern weather would make the central route impractical. To prove that the central route should be developed, the operators of the semimonthly stagecoach on that road began the celebrated pony express (q.v.) in April 1866.

During the Civil War, the Southern Overland Mail was removed to the central route, which was in union territory. Ben Holladay, an entrepreneur who became known as "the Napoleon of the plains," purchased the line in 1862 and extended it to Oregon and Montana.

Wells, Fargo and company purchased it in 1886. After the establishment of the first transcontinental railroad, it continued to operate for many years in local areas which were not served by a railroad.

SOUTHERN PACIFIC COMPANY, a U.S. transportation system, comprising, with its affiliated companies, railway and water lines, motor-truck routes and bus routes. It serves directly a large part of the United States west of the Mississippi river (at New Orleans, La.) through to the Pacific coast. It established steamship service between New York city and the ports of New Orleans, Galveston, Houston, Boston, New Bedford, Baltimore and Norfolk. Its lines were extended into Mexico as far south as Guadalajara. Its first unit, the Central Pacific main line, completed in 1869, was the link from California across the Sierra Nevada to Ogden, Utah, now 778 mi. from San Francisco, which completed the first through rail line across the North American continent. In 1883 the Sunset route was opened between New Orleans and San Francisco via El Paso and Los Angeles, distance now 2,472 mi. In 1887 the Shasta route was completed. giving a rail line between San Francisco and Portland, Ore., distance now 725 mi. Southern Pacific is also part of the Golden State route from Los Angeles to Chicago, its line, Los Angeles to Tucumcari, N.M., 1,145 mi., being about half the distance to Chicago.

The construction of Central Pacific and Southern Pacific and the merged operation of both was under the inspiration of four citizens of Sacramento: Leland Stanford, Collis P. Huntington, Mark Hopkins and Charles Crocker. Stanford, prior to his death, founded and endowed Stanford university. After the fleath of these men E. H. Harriman secured control and carried to conclusion projects previously planned, including the straight and level 102-ml. line from Lucin to Ogden, of which 31½ ml. were built across Great Salt lake.

In 1952 the Southern Pacific operated 15,055 mi. of road.
(A. D. McD.)

SOUTHEY, CAROLINE ANNE (1786-1854), second

wife of Robert Southey  $(q\ v.)$  and the daughter of an East Indian captain, Charles Bowles, was born at Lymington, Hants. on Oct. 7, 1786. After her mother died in 1816 she was left in dire financial straits through the fraudulence of a guardian. In order to support herself, she determined to turn her talents to account in literature. She sent anonymously to Southey a narrative poem called "Ellen Fitzarthur," which may be taken as typical, in its prosy simplicity, of the rest of the author's work.

Southey became interested in her, and their acquaintanceship and long friendship developed through a correspondence that lasted 20 years. Southey was visited by her at Keswick, and, while there, she was shown the surrounding countryside by Wordsworth.

A combination of prose and verse in eight volumes, Solitary Hours, was published in 1826. This was succeeded by her work Chapters on Churchyards, a group of stories first published in Blackwood's Magazine and later in complete form in 1829. Her writing was simple yet had power and a strong element of pathos.

She was at her best in prose or blank verse rather than in lyric, since her main gift was as a teller of stories. On the appearance in 1836 of her longest poem, "The Birthday," Henry Nelson Coleridge called her "the Cowper of our modern poetesses."

Öther prose writings which were published included Tales of the Moors (1828) and Selwyn in Search of a Daughter (1835). Besides the works already mentioned, Mrs. Southey wrote The Widow's Tale, and Other Poems (1822) and Robin Hood in conjunction with Southey, at whose death the poem was incomplete.

In 1839 she was married to Southey. Soon after the marriage, however, her husband's mental state became hopeless. From that time till his death in 1843, and indeed till her own, her life was a sad one. She was not on good terms with her stepchildren, and her share in Southey's life was hardly noticed in Charles Cuthbert Southey's Life and Correspondence of his father. But with Edith Southey, who was the wife of J. W. Warter, she was always in friendly relations, and she supplied the valuable additions to Southey's correspondence published by Warter.

Her correspondence with Southey, neglected in the official biography, was edited by Edward Dowden in 1831. Mrs. Southey died at Buckland cottage, Lymington, on July 20, 1854, two years after Queen Victoria had granted her an annual pension of £200.

**SOUTHEY, ROBERT** (1774–1843), English poet and man of letters, was born at Bristol on Aug. 12, 1774. His father, Robert Southey, an unsuccessful linendraper, married Margaret Hill in 1772.

1772.
When he was three, Southey passed into the care of Elizabeth Tyler, his mother's half-sister, at Bath, where most of his child-hood was spent. Miss Tyler was a whimsical and despotic person, of whose household he left an amusing account in the fragment of autobiography written in a series of letters to his friend John May. Before Southey was eight years old he had read Shakespeare and Beaumont and Fletcher, while his love of romance was fostered by the reading of Hoole's translations of Tasso and Ariosto, and of the Faerie Queene.

In 1788 he was entered at Westminster school. After four years there he was privately expelled by William Vincent (1730-1815) for an essay against flogging called "The Flagellant," written for a school magazine. At Westminster he made two friends who proved faithful and helpful to him through life—Charles Watkyn Williams Wynn and Grosvenor Bedford. His uncle, Herbert Hill, chaplain of the British factory at Lisbon, who had paid for his education at Westminster, determined to send him to Oxford with a view to his taking holy orders, but the news of his escapade at Westminster had preceded him, and he was refused at Christ Church. Finally he was admitted at Balliol, where he matriculated on Nov. 3, 1792, and took up his residence in the following January. His father dide soon after his matriculation. At Oxford he lived a life apart and gained little or nothing from the university except a liking for swimming and a knowledge of Epictetus.

Revolutionary Youth.—In the vacation of 1793 Southey's enthusiasm for the French Revolution found vent in writing an epic poem, Joan of Arc, published in 1796 by Joseph Cottle, the Bristol bookseller. In 1794 Coleridge, then on a visit to Oxford,

was introduced to Southey, and filled his head with dreams of an American Utopia on the banks of the Susquehanna. The members of the "pantisocracy" were to earn their living by tilling the soil, while their wives cared for the house and children. Coleridge and Southey soon met again at Bristol, and with Robert Lovell developed the emigration scheme. Lovell had married Mary Fricker, whose sister Sara married Coleridge, and Southey became engaged to a third sister, Edith. Miss Tyler, however, would have none of "pantisocracy" and "aspheterism," and drove Southey from her house. To raise the necessary funds for the enterprise Coleridge and he turned to lecturing and journalism. Cottle generously gave Southey £50 for Joan of Arc; and, with Coleridge and Lovell, Southey dashed off the drama, printed as the work of Coleridge, The Fall of Robespierre. A volume of Poems by R. Southey and R. Lovell was also published by Cottle in 1795.

Southey's uncle, Hill, desired him to go with him to Fortugal. Before he started for Corunna he was married secretly (Now-1795) to Edith Fricker. On his return to England his marriage was acknowledged, and he and his wife had lodgings for some time at Bristol. He was urged to undertake a profession, but the church was closed to him by the Unitarian views he then held, and medicine was distasteful to him. He was entered at Gray's Inn in Feb. 1797 and made a serious attempt at legal study, but with small results. At the end of 1797 his friend Wynn began an allowance of £160 a year, which was continued until 1806, when Southey relinquished it on Wynn's marriage. His Letters Written During a Short Residence in Spain and Portugal was printed by Cottle in 1797, and in 1797-09 appeared two volumes of Minor Poems from the same press.

In 1798 he paid a visit to Norwich, where he met Frank Sayers and William Taylor, with whose translations from the German he was already acquainted. He then took a cottage for himself and his wife at Westbury near Bristol, and afterward at Burton in Hampshire. At Burton he was seized with an illness which had been threatening for some time. He moved to Bristol, and after preparing for the press his edition of the works of Thômas Chatterton, undertaken for the relief of the poet's sister and her child, he sailed in 1800 for Portugal, where he began to accumulate meterials for his history of Portugal. He also had taken with him the first six books of Thôlaba the Destroyer (1801), and the remaining six were completed at Cintra. The unrhymed, irregular metre of the poem was borrowed from Sayers.

Life at Greta Hall.-In 1801 the Southeys returned to England, and at the invitation of Coleridge, who held out as an inducement the society of Wordsworth, they visited Keswick. After a short experience as private secretary to Isaac Corry, chancellor of the exchequer for Ireland, Southey in 1803 settled at Greta hall, Keswick, which he and his family shared thenceforward with the Coleridges and Mrs. Lovell. There he accumulated a library of more than 14,000 volumes, including valuable manuscripts and a collection of Portuguese authorities probably unique in England. After 1809, when Coleridge left his family, the whole household was dependent on Southey's exertions. His nervous temperament suffered under the strain, and he found relief in keeping different kinds of work on hand at the same time, in turning from the History of Portugal to poetry. Madoc and Metrical Tales and Other Poems appeared in 1805, The Curse of Kehama in 1810, Roderick, the Last of the Goths, in 1814.

This constant application was lightened by a happy family life. Southey was devoted to his children and was hospitable to the many friends and even strangers who found their way to Keswick. His friendship for Coleridge was qualified by a natural appreciation of his failings, the results of which fell heavily on his own shoulders, and he had a great admiration for Wordsworth. He met Walter Savage Landor in 1808, and their friendship lasted until Southey's death.

From the establishment of the Tory Quarterly Review Southey, whose revolutionary opinions had changed, was one of its most regular and useful writers. He supported church and state, opposed parliamentary reform, Roman Catholic emancipation and free trade. He did not cease, however, to advocate measures for the immediate amelioration of the condition of the poor,

With William Gifford, his editor, he was never on very good terms, and would have nothing to do with his harsh criticisms on living authors. His relations with Gifford's successors, Sir J. T. Coleridge and Lockhart, were not much better. In 1813 the laureateship became vacant on the death of Pye. The post was offered to Scott, who refused it and secured it for Southey. A government pension of some £160 had been secured for him, through Wynn, in 1807, increased to £300 in 1835. In 1817 the unauthorized publication of an early poem on Wat Tyler, full of his youthful republican enthusiasm, brought many attacks on Southey. He was also engaged in a bitter controversy with Byron, whose first attack on the "ballad-monger" Southey in English Bards and Scotch Reviewers nevertheless did not prevent them from meeting on friendly terms. Southey makes little reference to Byron in his letters, but Byron asserts (Letters and Journals, ed. Prothero, iv. 271) that he was responsible for scandal spread the self and Shelley. In this frame of mind, due as much to personal anger as to natural antipathy to Southey's principles, Byron dedicated Don Juan to the laureate, in what he himself called "good, simple, savage verse." In the introduction to his Vision of Judgment (1821) Southey inserted a homily on the "Satanic School" of poetry, unmistakably directed at Byron, who replied in the satire of the same name. The unfortunate controversy was renewed even after Byron's death, in consequence of a passage in Medwin's Conversations of Lord Byron.

Meanwhile the household at Greta Hall was growing smaller. Southey's eldest son, Herbert, died in 1816, and a favourite daughter in 1826; Sara Coleridge married in 1829; in 1834 his eldest daughter, Edith, also married; and in the same year Mrs. Southey, whose health had long given cause for anxiety, became insane. She died in 1837, and Southey went abroad the next year with Henry Crabb Robinson and others. In 1839 he married his friend Caroline Bowles. (See Southey, Caroline.) But his memory was failing, and his mental powers gradually left him. He died on March 21, 1843, and was buried in Crosthwaite churchyard. A monument to his memory was erected in the

church, with an inscription by Wordsworth.

Works.-The amount of Southey's work in literature is enormous. His collected verse, with its explanatory notes, fills ten volumes, his prose occupies about forty. But his greatest enterprises, his history of Portugal and his account of the monastic orders, were left uncompleted, and this, in some sense, is typical of Southey's whole achievement in the world of letters; there is always something unsatisfying, disappointing, about him. This is most true of his efforts in verse. Some of Southey's subjects, "The Poet's Pilgrimage" for instance, he would have treated delightfully in prose; others, like the "Botany Bay Eclogues," "Songs to American Indians," "The Pig," "The Dancing Bear," should never have been written. Of his ballads and metrical tales

If we turn from his verse to his prose we are in a different world; there Southey is a master in his art, who works at ease with grace and skill. "Southey's prose is perfect," said Byron, truly. His interest and his curiosity are unbounded as his Common-Place Book will prove; his stores of learning are at his readers' service, as in The Doctor, a rambling miscellany, valued by many readers beyond his other work. For biography he had a real genius. The Life of Nelson (2 vols., 1813), which has become a model of the short life, arose out of an article contributed to the Quarterly Review; he contributed another excellent biography to his edition of the Works of William Cowper (15 vols., 1833-1837), and his Life of Wesley; and the Rise and Progress of Methodism (2 vols., 1820) is only less famous than his Life of Nelson. But the truest Southey is in his Letters: the loyal, gallant, tender-hearted, faithful man is revealed.

A collected edition of his Poetical Works (10 vols., 1837-38) was followed by a one volume edition in 1847. Southey's letters were edited by his son Charles Cuthbert Southey as The Life and Correspondence by ms son charges Cutinert, Souther as I he Lage and Correspondence of the late Robert Southey (6 vols., 1849-50); further selections were published in Selections from the Letters of Robert Southey (4 vols., 1856), edited by J. W. Warter; and The Correspondence of Robert

Southey with Caroline Bowles. To which are added: Correspondence with Shelley, and Southey's Dreams (1881), was edited, with an introduction, by Professor E. Dowden. An excellent selection from his whole correspondence, edited by Mr. John Dennis, as Robert Southey, the story of his life written in his letters (Boston, Massachusetts, 1887), was reprinted in Bohn's Standard Library (1894). See also Southey (1879) in the English Men of Letters Series, by Professor E. Dowden, who also made the selection of Poems by Robert Southey (1893) in the Golden Treasury Series. W. Haller, Early Life of Robert Southey (1774-7803) (Columbia, 1917). A full account of his relations with Byton is given in The Letters and Journals of Lord Byron (vol. vi. 1901, edited "Quarrel between In the Letter's that Southest of the Southest of Lorentz of Lorent Southey and Porson, and two between Southey and Landor.

SOUTH GEORGIA, an island in the South Atlantic Ocean, 800 mi. E. of the Falkland Islands, of which it is a dependency. Length is 100 mi., maximum breadth 20 mi., and area 1,450 sq.mi.; est. pop. (1941) 360. Chief settlement is Grytviken, in Cumberland bay, on the N. coast; it has a wireless station and is served by a vessel of the Falkland Islands company. Whaling is the sole industry. Captain Cook claimed the island for Great Britain in 1775. "Discovery II" made coastal surveys during 1926-30.

See L. H. Matthews, South Georgia (1931); D. Ommaney, South Latitude (1938), in the U.S. titled Below the Roaring Forties (1938).

SOUTH HADLEY, a town of Hampshire county, Massachusetts, U.S.A., occupying 18.5 sq.mi. on the Connecticut river, 12 mi. N. of Springfield, directly opposite Mt. Tom. It is served by connections with the Boston and Maine railway at Holyoke, across the river. The population was 10,145 in 1950; (1940) 6,856; (1930) 6,773 by the federal census. Mount Holyoke college (established 1837) is at South Hadley.

SOUTH HOLLAND, the most crowded province of the Netherlands; area, 1,133 sq.mi.; pop. 2,382,898 (1950). The province has strips of dunes, geest lands, low fen and clay but the southwest area consists of ramifications of the Lek, Mads and Waal producing a mozaic of islands such as Dordrecht, Voorne-Putten, etc.; Goeree-Over Flakkee is wholly detached. Traffic from East Britain converges on the coastal Hook of Holland harbour (built 1866-1872) en route by water or rail for the Rotterdam (q.v.), Schiedam (72,630) industrial area with Dordrecht (70,793) farther southeast on the Rotterdam-Antwerp route. Many old sites along the "dune-foot" line have decayedthe famed Teilengen castle (near Sassenheim) where Jacqueline of Bavaria died (1433) has almost disappeared-but The Hague (q.v.) remains the capital of both province and kingdom. Eastward is the triangle of towns: Leyden (86,914), university, and Delft (64,876), pottery, with Gouda (37,283), cheese and earthenware. East and south on the borders are the historic rivers sites of Vianen (Lek), the reputed Fanum Dianae of Ptolemy and Gorichem (Waal),-taken by the "Sea Beggars" from the Spaniards (1572). South Holland suffered perhaps more than any many have passed into familiar use as poems for the young.

Among these are "The Inchcape Rock," "Lord William," "The subjected to widespread destruction by aerial bombing on May Battle of Blenheim," and the ballad on Bishop Hatto.

In 1949, South Hohand suffered perhaps in the thair any subjected to widespread destruction by aerial bombing on May Battle of Blenheim," and the ballad on Bishop Hatto. 14, 1940; the whole business centre was wiped out and at least 25,000-30,000 persons were killed. During the winter of 1942-43 the Germans tore down at least 20,000 homes and the famous 17th century wood, Haagsche Bosch, in The Hague, in order to build defense works. The sea resort of Scheveningen was also razed to a large extent.

SOUTH KINGSTOWN, a town of Rhode Island, U.S.A. Pop. (1950) 10.145. It is an old tree-shaded town, on an arm of Point Judith salt pond, and has colonial houses. In Great Swamp on Dec. 19, 1675 the Narragansett Indians made their last stand in King Philip's War, and were defeated by the forces of the Massachusetts, Plymouth and Connecticut Colonies under Governor Josiah Winslow (of the Plymouth Colony).

SOUTH METROPOLITAN GAS COMPANY. This undertaking in London possesses by statute the sole right to supply gas to nearly the whole of the county of London south of the Thames, with nearly two million people. It is an amalgamation of supply companies, completed in 1885.

In 1938 the South Metropolitan company had behind it a history of 114 years of enterprise. It was in 1802 that William Murdock, the friend and assistant of Matthew Bolton and James Watt, lit with coal gas the famous engine works at Soho, near Birmingham, and gas lighting was used in London for the first time when the Carlton Palace Gardens were illuminated by an enterprising German named Winsor. The company began work very soon after the first experiments were made. (L.C.M.)

SOUTH MILWAUKEE, a city of Milwaukee county, Wis., U.S., on Lake Michigan, 10 mi. S. of Milwaukee; served by the Chicago and North Western railroad. Pop. (1950) 12,855; (1940) II.134 by federal census. The city was founded in 1892 and in-

corporated in 1897

SOUTH MOLTON, a municipal borough in Devonshire, Eng., 12 mi, S.E. of Barnstaple by road, on the river Mole. Pop. (1951) 3,125. Area 9.24 sq.mi. There are flour mills and factories for shirts and collars. It is a tourist centre for Exmoor with a Perpendicular church. The weekly market and one fair date from 1246, and the fair held on St. John the Baptist's day dates from

SOUTHOLD, a township of Suffolk county, N.Y., occupying the peninsula at the northeast of Long Island, and including the islands east-northeast of this peninsula; Plum Island, on which defenses protect the eastern entrance to Long Island sound. Little Gull Island, Great Gull Island and Fisher's Island. Pop. (1950) 11,632. The mainland area is about 25 mi. long and its average width is 2 mi. A permanent settlement was made in 1640.

A meeting house was built in 1642, and biblical laws were enforced Southold was originally one of the six towns under the New Haven jurisdiction, but in 1662 was placed under Connecticut; in 1664 it objected strongly to the transfer of Long Island to the duke of York; in 1670 refused to pay taxes imposed by Gov. Francis Lovelace of New York; in 1672 petitioned the king to be under Connecticut or to be a free corporation; in 1673, when the Dutch got control of New York, withstood the Dutch commissioners, with the help of Connecticut; and, in 1674, after English supremacy was again established in New York, still hoped to be governed from Connecticut. The township was chartered by Gov. Edmund Andros in 1676.

See Epher Whitaker, History of Southold, L.I.: Its First Century (1887); Southold Town Records, 2 vol. (1882-84); Peter Ross, A History of Long Island (1902); Ella B. Hallock, The Story of the 275th Anniversary Celebration of the Founding of Southold Town (1918); B. F. Thompson, History of Long Island (1918); Ann Currie-Bell, Old Southold Town's Tercentenary (1940).

SOUTH ORANGE, Essex county, N.J., only chartered village in the state, between Orange and Maplewood. Pop. (1950) 15,230 by federal census. It is a residential community, 300 ft. above sea level. Among the landmarks are an old stone house mentioned in documents as early as 1680, the Baldwin house (c. 1717) and the Timothy Ball house (1743).

SOUTH PASADENA, a suburban city of Los Angeles county, Calif., U.S. Pop. (1950) 16,935. It is located on the Arroyo Seco parkway, nine minutes from downtown Los Angeles. It is noted for its fine climate, beautiful homes and good schools.

SOUTHPORT, a municipal, county and parliamentary borough, Lancashire, Eng. Pop. (1951) 84,057. Area 15 sq.mi. Extending 8 mi, along the coast between Liverpool and Preston, it is a very popular holiday resort with a large residential population. The present town was built on wind-blown sand and reclaimed land during the 19th century. Southward the coast is bordered by high sand dunes while inland the ground is marshy. Southport was known as Meols (Scandinavian "sand dunes") until the early 19th century. Liberal planning, with emphasis on gardens and flowers, produced handsome thoroughfares such as Lord street and several parks. The annual flower show is famous. Engineering is the most important industry. Southport returns one member to parliament,

SOUTH PORTLAND, a city of Maine, U.S., opposite Portland, with which it is connected by four bridges. Pop. (1950) 21,866. The state reform school for boys is there. Until 1895 South Portland was part of the town of Cape Elizabeth.

SOUTH RIVER, a borough of New Jersey, U.S., served by the Raritan River railroad. Pop. (1950) 11,308. There are operated by the borough meets the costs of government. A settlement was established there in 1720 by Samuel Willett. The bor-

ough was incorporated in 1896. SOUTHSEA: see PORTSMOUTH.

SOUTH SEA BUBBLE, the name given to a series of financial projects which originated with the incorporation of the South Sea Company. In 1711 the South Sea Company was formed, and was granted a monopoly of the British trade with South America and the Pacific islands. It was highly successful, and early in 1718 the king became its governor. Towards the end of 1710 the directors of the company put before the Government, the head of which was Charles Spencer, 31d earl of Sunderland, a more anibitious scheme. In return for further concessions the company offered to take over the whole of the national debt (£51.300.000) and to pay £3,500,000 for this privilege. The aim of the directors was to persuade the annuitants of the State (the bulk of the debt was thus held) to exchange their annuities for South Sea stock:

the stock would be issued at a high premium and thus a large amount of annuities would be purchased and extinguished by the issue of a comparatively small amount of stock. Moreover, when this process had been carried out the company would still receive from the Government a sum of something like £1,500,000 a year in interest. The offer was accepted in 1720, the company having

raised its bid to £7,567,000 in competition with the directors of

the Bank of England.

In a few weeks the company had persuaded over one-half of the Government annuitants to become shareholders in the company. Meanwhile the stock of the company had been appreciating steadily in value, and when the new scheme was launched the public began to purchase it eagerly. From 1284 at the beginning of the year the price had risen by June to 800, and in July it touched 1,000. At this tremendous premium the directors sold five millions of stock. The extraordinary success of the company produced a crowd of imitations-many of them audacious hoaxesand the wild speculation which followed involved the numerous honest companies in disaster. In August the fall in the price of South Sea stock began. By November it had fallen to 135, and in four months the stock of the Bank of England fell from 263 to 145. Thousands were ruined, and many who were committed to heavy payments fled from the country. A committee of secrecy of the House of Commons reported in February 1721. company's books contained fictitious entries, and it was shown that favours secured from the State had been purchased by gifts to ministers, some of whom had also made large sums of money by speculating in the stock. The chief persons implicated were John Aislabie (1670-1742), chancellor of the exchequer; James Craggs, joint postmaster-general; his son James Craggs, secretary of state; and to a lesser degree the earl of Sunderland and Charles Stanhope, a commissioner of the Treasury. Aislable resigned his office in January, and being found guilty of the "most notorious, dangerous and infamous corruption," was expelled from the house and imprisoned. Both the elder and the younger Craggs died in March, while, owing to the efforts of Walpole, both Sunderland and Stanhope were acquitted, the latter by the narrow majority of three. By act of Parliament the estates of the directors were confiscated; these were valued at £2,014,123, of which £354,600 was returned to them, the balance being devoted to the relief of the sufferers. The company continued to exist until the 19th century.

SOUTH SHETLANDS, a chain of islands in the South Atlantic ocean, with Graham's Land constituting a group of dependencies of the Falkland Islands (q.v.). The northern point of the South Shetlands is about 500 mi. S. of the Falklands. While there is no permanent population, the group is visited periodically by whalers, whose base is Port Foster, on Deception Island. Instances of volcanic activity have been numerous since the first definite record of an earthquake in 1923. The water in the harbour of Port Foster frequently becomes agitated by the subterranean heat, the shores in places being obscured by the dense vapour emitted. The South Shetlands were sighted and taken possession of for Great Britain by Captain Cook in 1775. William Smith, of the brig "Williams," landed on King George I Island in brick and tile works. Profit from the public utilities owned and 1819, and in 1820 Captain Bransfield examined the group. Coastal surveys were made by "Discovery II" during 1925-33.

See A. G. Bennett, Whaling in the Antarctic (1931); E. R. Gun-

ther, Notes and Sketches Made during Two Years on the Discovery Expedition, 1925-27 (1928).

SOUTHWARK, a central borough of London on the south bank of the River Thames. Pop. (1951) 97,191. Area 1.8 sq mi. It is connected with the City of London by Blackfriars, London and Southwark bridges. The convergence of roads to cross London bridge gave Southwark its mediaeval importance, and its inns became famous (e.g., the Tabard of the Canterbury Tales and the George, the last surviving galleried inn in London, now owned by the national trust). In 1337 Edward III granted Southwark to the citizens of London forever and its title of "The Borough" still survives; the charter was renewed by Edward IV and Edward VI, when the ward of Bridge Without was constituted (1550), the alderman of which is not elected but is the senior alderman of the time. The authority of the City over the borough is now merely nominal.

The name Southwark is taken from the southward works, or fortifications, of London. Numerous Roman remains have been found. The hospital of St. Thomas, founded in 1213, was removed to Lambeth in 1868; its chapel became the chapter house of the cathedral. Opposite is Guy's hospital, founded by Thomas Guy in 1722. Various bishops had town houses in Southwark; the grandest was Winchester house, used for five centuries from 1107. Paris garden was a centre of amusement in the 16th and 17th centuries, and in it were bear gardens and the Swan theatre (1595, burned down 1633). The Globe theatre, where many of Shakespeare's plays were produced, was built in Bankside in 1599 and was burned down in 1613.

The Augustinian priory of St. Mary Overie (over rie=over the water), founded in 1106, became the parish church of St. Saviour in 1540. In 1905, when the diocese of Southwark was created, it became the cathedral church and in 1937 was renamed the Cathedral and Collegiate Church of St. Saviour and St. Mary Overie. It lies well below the level of the streets at the southern end of London bridge. Built in the 13th and 14th centuries (the original having been burned down), it was restored in the 19th century. The choir and Lady chapel are Early English, the transepts are Decorated and Perpendicular and the nave is 19th century. The Harvard memorial chapel was restored in 1907 in memory of John Harvard, the founder of Harvard university. There is also a Roman Catholic cathedral.

SOUTHWELL, ROBERT (c. 1561–1595), English Jesuit and poet, son of Richard Southwell of Horsham St. Faith's, Norfolk, was born in 1560/61. He was educated at Douai and at Paris, joining the Society of Jesus. In 1584 an act was passed forbidding any English-born subject of the queen who had taken priest's orders in the Roman Catholic Church since her accession to remain in England longer than 40 days on pain of death. But Southwell at his own request was sent to England in 1586 as a Lesuit missionary with Henry Garnett. He went from one Catholic family to another, administering the rites of his church, and in 1589 became domestic chaplain to Ann Howard, whose husband, the first earl of Arundel, was in prison convicted of treason. It was to him that Southwell addressed his Epistle of Comfort. This and other of his religious tracts, A Short Rule of Good Life, Triumphs over Death, Mary Magdalen's Tears and a Humble Supplication to Queen Elisabeth, were widely circulated in manu-

script. That they found favour outside Catholic circles is proved by Thomas Nashe's imitation of Mary Magdalen's Tears in Christ's Tears over Jerusalem.

After six years of successful labour Southwell was arrested (1592). He was imprisoned at first in Richard Topcliffe's house, where he was repeatedly put to the torture in the vain hope of extracting evidence about other priests. Transferred to the gate-house at Westminster, he was so abominably treated that his father petitioned Elizabeth that he might either be brought to trial and put to death, if found guilty, or removed in any case from "that fifthy hole." Southwell was then lodged in the Tower, but he was not brought to trial until Feb. 1595. Much of his poetry, none of which was published during his lifetime, was probably written in prison. On Feb. 20, 1595, he was tried before the court of King's Bench on the charge of treason, and was hanged at Tyburn on the 21st. In 1920 he was beatified.

St Peter's Complaint with other Poems, published anonymously in 1595, was reprinted 13 times during the next 40 years. A supplementary volume entitled Maconiae appeared later in 1595, and A Foure fould Meditation of the foure last things in 1606. This, which is not included in Grosart's reprint (1872) in the Fuller Worthies Library, was published by Charles Edmonds in his Isham Reprints (1895). A Hundred Meditations of the Love of God, in prose, was first printed from a manuscript at Stonyhurst College in 1872.

See Sidney Lee's account in the Dict. Nat. Biog.; Alexis Possoz, Vie du Père R. Southwell (1866); and a life in Henry Foley's Records of the English Province of the Society of Jesus, i, 307–367 (1877). Foley's narrative includes copies of the most important documents connected with his trial, and gives full information of the sources.

SOUTHWELL, a town and rural district of Nottinghamshire, England, 14 mi, N.E. of Nottingham by road. The rural district of 55 parishes had a population (1951) of 39,705; area 185 sq.mi. It has hosiery works, a flour mill and an interest in the neighbouring market-garden area (Bramley seedling apples are said to come from Southwell), but is chiefly known for its minister, a successor of a 7th-century church generally attributed to Paulinus; certainly there was a church there in the 8th century. The present building was begun in the 12th century and has a Norman nave, transepts and towers, an Early English choir and a Decorated octagonal chapter house. It is cruciform and is 306 ft. long. There are no cloisters. Particularly noteworthy are the magnificent 14th-century stone rood screen, intricately carved, and the carved animals and foliage on the doors of (and within) the chapter house.

In 958 land at Southwell was granted to the archbishop of York by Edwy and a detailed description of the manor appears in Domesday Book. Southwell was a collegiate establishment and remained under the lordship of the see of York until it was taken over by the ecclesiastical commissioners. Remains of the archbishop's place (15th-century; "great chamber" restored 1880) are incorporated in the bishop's palace. The episcopal see founded in 1884 included the counties of Nottingham and Derby, but the latter was detached in 1926 when the see of Derby was established.

SOUTH-WEST AFRICA. Formerly a German colony, after 1920 this territory was administered under a League of Nations C-type mandate by the Union of South Africa. Its area is 317,725 sq.mi., excluding the Walvis Bay territory (374 sq.mi.), which is an integral part of the Union Cape province. The territory of South-West Africa lies between the lower Cunene and middle Okavango (Okovango, Cubango) rivers and the parallel of 17° 23'S, in the north, and the lower Orange river in the south, and between the Atlantic coast and the meridians of 20° and 21° E., the Caprivi corridor extending from the northeast corner about 275 mi. east to the Zambezi river.

Physical Features.—The territory falls into two distinct physiographic regions: the plateau, which extends eastward to the Kalahari desert, and the western marginal area, which includes the Namib coastal desert and the slopes ascending to the plateau edge. The highest part of the plateau is to the southwest, south and northeast of Windhoek where the Khomas, Auas and Onyati highlands have average altitudes of between 6,000 and 7,000 ft., the highest point being Molkteblick, 8,750 ft. The highest point in

the territory, however, is the isolated mass of the Brandberg, 8,550 ft., in the northern Namib. Large numbers of pans occur in the territory, the largest being the Etosha pan in the north which covers an area of about 1,404 sq.mi. Most of the pans are dry in the winter and contain water after the summer rains.

The climate is very dry in the south, becoming gradually moister northeastward; owing to the effect of the Benguela current the coastal area is cool, temperatures generally rising toward the interior. The rainfall of the Namib coastal belt is about one inch or less a year; inland the rainfall increases to about 12 in. in the centre and 22 in. in the north. Except for the Cunene and Okavango rivers in the north, the Zambezi and Linyanti (Cuando) in the northeast, and the Orange in the south, there are no perennial streams. Fresh water can generally be obtained from shallow wells in the beds of the intermittent streams.

Vegetation.—The Namib is almost devoid of vegetation near the coast except for such plants as can exist on account of the fogs, e.g., Sarcocaula, Aloe dichotoma and the Welwitschia bainesii About 25 mi. inland cacti and euphorbias appear, and in the river channels thorn trees (Acacia spp.) occur. On the plateau, in the south, semidesert conditions prevail, low shrubs and scant grass being the chief plants, with trees along the river beds. The commonest plants there are Salsola aphylla (the Ganna bush), Rhigolum trichotomum (the three thorn bush), Acacia girafue (Kameeldoorn) and species of aloes and euphorbias. Northward, as far as Rehoboth, karroo (dry tableland) conditions are characteristic. Then a parklike grass country studded with thorn trees is reached. From about Windhoek the country northward is covered with bush, mostly thorn trees. Toward the north the bush becomes thicker and includes belts of Mopane forest; about the Okavango the vegetation becomes more tropical. (J. H. WN.)

#### HISTORY

The first European to set foot in the territory was the Portuguese navigator Diogo Cão who planted a pillar at Cape Cross in his voyage of 1485-86. At the end of 1487 his compatriot Bartolomeu Diaz (Dias) touched at the modern Walvis Bay and at Diaz point, where he erected a pillar near Angra Pequena. It was not until 1670 that any serious effort to explore these shores was made. In that year the Dutch East India company's ship "Grundel" sailed up the coast and was followed by the same company's "Bode" in 1677. Though the interior still remained unknown, the coastal waters were not neglected; sealing and whaling attracted ships of various nationalities. Then, more than a century after the cruise of the "Bode," in 1793, Capt. F. R. Duminy, of the Dutch ship "Meermin," proclaimed certain areas to be the property of the Dutch government. In 1795, Capt. Alexander of H.M.S. "Star" hoisted the British flag at various points on the coast but his action was later disowned by his government. Meanwhile, in 1760, Jacobus Coetzee found a way into Great Namaqualand by the overland route from the Cape. He was followed in 1761-62 by Hendrik Hop and thereafter by a fairly steady stream of explorers of whom the most famous, and possibly the most successful among the later ones, was C. J. Andersson, a Swede, who in 1853 crossed from Walvis bay to Lake Ngami in Bechuanaland. The London Missionary society was represented on the Orange river as early as 1802 and in 1807 established a station at Warmbad. This society withdrew and was succeeded by the Wesleyans. In the 1840s, the German connection with the territory began with the arrival of the Rhenish Missionary society.

In 1868 tribal wars prompted the missionaries to appeal for British protection. In this they were actually supported by the German government, but the British government turned the proposal down. In 1876 the Cape colony sent a special commissioner, W. C. Palgrave, who made treaties with chiefs anxious to secure British protection. This placed the whole territory up to the Portuguese colony of Angola under British control. The British high commissioner in South Africa approved Palgrave's action but the British government was unwilling to assume these new responsibilities and was only with difficulty persuaded to consent to the annexation of Walvis Bay and some adjacent territory (1878). The guano islands off the coast had been annexed in 1867. In 1880

tribal war again broke out and the German government itself asked Great Britain to protect the life and property of its subjects but the British reply was negative.

Deutsch-Südwestafrika.—In 1883 Heinrich Vogelsang, agent of F. A. E. Luderitz, a merchant of Bremen, obtained from the Hottentot chief, Joseph Frederick of Bethany, a cession of land at Angra Pequena, later known as Lüderitz Bay. Bismarck, still unconverted to a colonial policy, caused the British government to be informed beforehand of the project in words that were almost an invitation to Great Britain to assume sovereignty over the territory and to act as protecting power. This opportunity, like the previous one, was allowed to slip away and in April 1884 Bismarck took the initiative and assured Lüderitz and his establishments of German protection. Belated attempts by the British and Cape governments to retrieve the situation were unavailing, and in due course protection over German traders developed into full-fledged German annexation of the whole territory. British anxiety—man designs in the territory and the lear that the Germans might join across the continent with the Boers of the Transval was one of the reasons that prompted the British government to declare a protectorate over Bechuanaland in 1884–85.

The first German representative, sent to the territory in 1885, was H. E. Göring. He was succeeded by Kurt von François, who transferred the capital from Otjimbingue to Windhoek. It was there that the first German farmers settled in 1893. In 1893 there was trouble with Hendrik Witbool, the Hottentot chief. The Germans statcked Witbool's village and 150 of his subjects, including women and children, were killed. Von François was succeeded in 1896 by Theodot Leutwein who tried to treat the natives with consideration. The latter found much cause for dissatisfaction, and it required only a spark to set the country ablaze. The Bondelswaartz Hottentots rose in 1903. This rising was suppressed, but early in 1904 the Herero revolted and killed a number of German (but not British or Boer) settlers. The rebellion was speedily quelled but in the "Cleaning up" operations the Herero were ferociously harried by Gen. Lothar von Trotha, Leutwein's successor from 1904, and were in the end reduced from a tribe of 80,000 people to 15,000 starving refugees, many of whom found sanctuary in Bechuanaland. Von Trotha was recalled toward the end of 1905 and his successor, Friedrich von Lindequist, a diplomat, extended an amnesty to the Herero. Various groups of Hottentots wfo had joined in the rebellion still held out, and it was not until early in 1907 that the war could be declared at an end.

In the years that followed these troubles the depopulation resulting from the methods used in suppressing the rebellion caused a labour shortage which hampered the development of the territory. The discovery of diamonds in 1908 near Lüderitz Bay led to a considerable increase in the European population which rose to nearly 15,000 by 1913. The government did much to encourage European enterprise, and though the territory never paid its way, there were, up to the outbreak of World War I, some hopes of future prosperity.

and though the territory never paid its way, there were, up to the outbreak of World War I, some hopes of future prosperity.

On Aug. 6, 1934, the government of the Union of South Africa undertook to assume all obligations resting upon the British regular garrison
in South Africa and on Aug. 10 to send a military expedition of its own
to German South-West Africa. Soon after the preliminary occupation of Lüderitz Bay the Boer rebellion interrupted operations but
once this was overcome the campaign against the Germans developed
rapidly and successfully. In Jan. 1915 South African forces advanced
into the country from different points and after a campaign of swift
movement in semidesert and waterless country forced the surrender of
the Germans on July 9, 1915.

The Union government treated the conquered Germans with much leniency. At the end of the campaign the German troops were interned and later (in 1979) repartiated with about 600 undesirables. German civilians, on the other hand, were allowed to return to their homes in the territory and to continue their ordinary pursuits.

Under the South African Mandate.—Under the treaty of Ver-

Under the South African Mandate.—Under the treaty of Versailles, Germany ceded its colonies to the principal Allied and associated powers. South-West Africa was designated as a C mandate and was conferred on "his Britannic majesty for and on behalf of the government of South Africa." The newly created League of Nations was charged, inter alia, with the supervision of mandates. Subject to the mandate South Africa was given full powers of legislation and administration over the territory as an integral part of the Union. The exercise of these powers was vested by the house of assembly in the governor-general (Union act 49 of 1970) who later delegated them to a resident administrator. The S.W.A. Naturalization of Allien act of 1924 provided for the automatic naturalization of all German adult males domicilled in the territory on Jan. 1, 1924, unless they specifically objected. Less than 300 Germans did object and 3,228 became British subjects.

During the first few years of the mandate the territory was administered somewhat after the fashion of a crown colony, with an administrator assisted by an advisory council. In 1926 a legislative assembly of 12 elected and 6 nominated members, with an executive committee was set up to legislate for subjects like roads and bridges, works, agri-

culture and taxation, while the rest of the administrative functions remained in the hands of the administrator

In general the natives accepted Union rule without difficulty In 1917 it became necessary to send a military force to Ovamboland where for it became necessary to send a minutary note to ovanious answers. German authority had been slight, but thereafter relations with the Ovambo were excellent. In 1922 the Bondelswaartz Hottentots, moved by various grievances, rose in revolt. The rising was suppressed in a manner that gave lise to criticism and provoked an inquity. In 1925 the Bastaards of Rehoboth, a group of mixed descent, defied the the Bastaards of Rehoboth, a group of mixed descent, defied the authority of the government but the matter was settled without bloodshed.

Until the rise of Hitler the Germans in the territory had been reasonably co-operative. By 1933 they changed their attitude and were gradually almost all absorbed in the Nazi complex. By 1939 the grip of the National Socialist party on all Germans in the territory was practically complete. At the outbreak of World War II the Union government acted with dispatch. By Dec. 1939 about 150 Nazi leaders were arrested and the organizations themselves proscribed. By Oct. 1040 the number of persons interned was 1,200 or one-third of the German adult male population. By the Naturalization and Status of 

Germans reverted to their former German status.

Trusteeship or Incorporation?—At the end of World War II, South Africa became involved in an international controversy on two South Africa decade involved in an international controvery on two questions affecting the territory. The first was that of trusteeship, the second of incorporation of South-West Africa in the Union. With the demise of the League of Nations the Union government held that there was nothing in the covenant that empowered it to

transfer or delegate its powers as regards mandates to any organization In this contention South Africa was supported in 1950 by an opinion of the International Court of Justice, which held that the Union was under no obligation to place the territory under a United Nations trusteeship, but that on the other hand an obligation rested on South Africa to submit reports on the administration of the territory to the UN. In spite of pressure South Africa firmly refused to agree to the inclusion of the territory in the international trusteeship system, but was willing to submit reports to Great Britain, the United

States and France as a matter of courtesy.

The proposal that South-West Africa should be incorporated in or should become a fifth province of the Union arose in 1946 when the subject was referred to a series of tribal meetings and it was reported that the majority of natives was in favour of the proposal, the Herero being the only substantial body against it. Later in the same year Gen. J. C. Smuts asked the United Nations that the territory should be incorporated in accordance with the wish of its people but the request was refused. The South African government did not press the demand but declared its intention, and this applied both to trusteeship and to incorporation, to continue to administer South-West Africa in the spirit of the mandate. However, the association of the two countries, already close, was made much closer by the South-West African Affairs (Amendment) act of 1949, which gave the territory six elected representatives in the Union house of assembly and four in the senate, of whom two are elected and two nominated by the governor-general. The same act substituted for the 12 elected and 6 nominated members of the legislative assembly a wholly elected body of 18 members. The South African Citizenship act of 1949 made it possible for those who had been "denaturalized" in (Ay. Sy.) 1942 to apply once more for naturalization.

# POPULATION, ADMINISTRATION AND ECONOMY

In 1951 the population, exclusive of Walvis Bay, numbered 414,601, including 48,588 Europeans, 3 Asiatics and 366,010 natives (including coloured). Among the native inhabitants are Bushmen, Nama or Hotcoloured). Ämong the native inhabitants are Bushmen, Nama or Hotientots, Ovambo and Herero or Damara. The administrative capital, Windhoek, had in 1951 a population of 11,000 Europeans and 9,500 non-Europeans. Other towns with a European population of 800 or more were (1946): Ketemanshoop (1,673), the centre of a small mining industry; Swakopmund (1,569), the former German port serving Windhoek; Lüderitz (834), the southern seaport. Walvis Bay in 1946 had 646 Europeans and 1,778 non-Europeans.

Education—Primary education is free but fees are charged for secondary education. Native and coloured education is largely under the supervision of missions, though the state pays the teachers, supplies free furniture and equipment, and subsidizes the sale of books and stationary. There were, in 1051, 26 coloured schools with 2,336

and stationery. There were, in 1951, 26 coloured schools with 2,336 pupils and 229 native schools with 21,000 pupils.

The usual medical services were provided, and there were hospitals

in most centres.

Administration.—The territory is divided into a "police zone" to the south of the Eleoha pan and the Kaokoveld, in which the European population resides, and the northern native area which includes mainly the Kaokoveld, Ovamboland and the Okavango native territory, including the Captivi strip. There are r6 magisterial districts under magistrates who have both judicial and administrative functions. In the native areas the system of rule is "indirect"; that is to say, the people are ruled as far as possible through their own thefs, whose traditional powers and duties are preserved in so far as a far as Administration. -The territory is divided into a "police zone" these do not conflict with justice and humanity. All civil disputes between natives and all crimes committed by natives, except capital

offenses, are tried by the native authorities according to native law and custom.

Agriculture and Trade.-In the moister northern area, maize, potatoes, pumpkins and beans are grown, and farther south are several good artesian wells which offer opportunities for irrigation and the growth of wheat, but the country is in general better suited to pas-toralism. Sheep, goats and cattle are raised, the Karakul sheep industry being particularly noteworthy Karakul pelts head the list of agricul-tural exports overseas, mainly to the United States Pelts to the number of 2,398,863 were exported in 1949. The numbers of the principal animals returned at the livestock census of 1946 were: cattle 1,340,950, karakuls (grade) 2,488,837, goats 7,54,807, horses 37,120, donkeys 73,707. In addition to these there were in the natives' reserves 395,945 large stock and 548,441 small stock.

large stock and \$48,441 small stock.

Among the minerals exported in 1949 were (in short tons); lead and copper concentrates 79,445 (value \$2,80,000), lead and vanadium concentrates 9,242 (\$2,66,000), zinc concentrates 25,830 (\$2,58,3000); 252 carats of diamonds were sold for \$5,200,000. Other less important minerals exported included tin concentrates and salt, with phosphates (guano), beryl, lithium, graphite and tungsten in small amounts.

Transport and Communications.—There are 1,470 mi. of rail-way linking up the chief towns and joining the South African railway system (from Upington in the Cape province) at the southeastern

system (from Upington in the Cape province) at the southeastern border of the territory.

A system of main roads links Windhoek with Otavi, Walvis Bay, and Lüderitz via Keetmanshoop. Near Keetmanshoop another road takes off to the southeastern border where it joins the Union system.

The postal service, which provides the usual facilities for letters, telegrams and telephones, also includes such business as saving bank accounts, money orders and postal orders. It extends to every district, and in addition there are wireless transmitting and receiving sets at remote stations which are not served by land telegraph and telephones.

There are commercial airports at Windhoek, Keetmanshoop and

There are commercial airports at windhoek, Keetmanshoop and Alexander Bay.

SOUTH-WESTERN ISLANDS or SERWATTI ISLANDS, the

name of two chains of islands in the Banda sea, of the Malay Archipelago. Wetar, the largest island, is 70 mi, by 20 mi. They are a part of the Netherlands Indies.

Administratively the islands form part of the division Tual, residency of the Moluccas. The estimated population of all the islands is about 40,000, Wetar having 7,500. Kisar has as settlers the descendants of European soldiers of the time of the old Dutch East India company.

SOUZA-BOTELHO, ADÉLAIDE FILLEUL, MARQUISE DE (1761-1836), French writer, was born in Paris on May 14, 1761. Her mother, Marie Irène Catherine de Buisson, daughter of the seigneur of Longpré, near Falaise, married a bourgeois of that town named Filleul. It was reported, though no proof is forthcoming, that Mme. Filleul had been the mistress of Louis XV. Her husband became one of the king's secretaries, and Mme. Filleul made many friends, among them Marmontel. Their eldest daughter, Julie, married the marquis de Marigny (1727-1781); Adélaide married in 1779 Alexandre de Flahaut de la Billarderie, comte de Flahaut, who was many years her senior. In Paris she soon gathered round her a salon, in which the principal figure was Talleyrand. There are many allusions to their liaison in the diary of Gouverneur Morris. In 1785 was born her son Auguste Charles Joseph de Flahaut (q.v.), who was generally known to be Talleyrand's son. Mme. de Flahaut fled from Paris in 1792 and joined the society of émigrés at Mickleham, Surrey, described in Mme, d'Arblay's Memoirs. Her husband remained at Boulogne, where he was arrested on Jan. 29, 1793, and guillotined. Mme. de Flahaut now supported berself by writing novels, of which the first, Adèle de Sénange (London, 1794), which is partly autobiographical, was the most famous. She presently left London for Switzerland, where she met Louis Philippe, duke of Orleans. She travelled in his company to Hamburg, where she lived for two years, earning her living as a milliner. She returned to Paris in 1798, and in 1802 she married José Maria de Souza-Botelho Mourão e Vasconcellos (1758-1825), Portuguese minister plenipotentiary in Paris. Mme. de Souza lost her social power after the fall of the First Empire. She died on

SOVA, ANTONIN (1864-1928), Czech poet, began his literary career early in the '90s with verse, describing Prague and his native region of Southern Bohemia. His introspective poems, in Lyrics of Love and Life, Mastered Sorrows and Once Again Shall We Return, include good lyrics, and he has been compared with Verlaine. Disillusionment drove him to seek escape in visionary poems which reveal symbolism. In 1913 appeared Harvests, a volume in which reconciliation predominates. In some Sova is the spokesman of Czech aspirations. He also wrote novels and short stories.

SOVEREIGN: see Numismatics: British Coins; Pound STERLING.

SOVEREIGNTY. While society is in a rude state or only tribally organized there is no distinct sovereignty, no power which all persons habitually obey. Thus there is no sovereignty among wandering groups of Australian savages: each family is isolated, each horde is a loose and unstable collection. When the horde has become a tribe there may exist no definite sovereign. Distinct in time of war, the power of the chief may be fluctuating and faint in time of peace; even in time of war it may be subject to the authority of a council. Tribes of the same ethnic stock may form a sort of federation, permanent or temporary. "With the council of the confederacy," it has been said, "and, more generally, in the confederacy, sovereignty arises and the true political tradition is evolved" (F. H. Giddings, Principles of Sociology, p. 285). When the city and the State are conterminous the seat of sovereignty becomes defined. Such was the condition of things in Greece, as considered by Aristotle in his Politics. He discusses the question what is the supreme power in the State (3. 10), which he defines as an aggregate of citizens (3. i.), and he recognizes that it may be lodged in one, a few, or many. In his view the distinctive mark of the State is not so much sovereignty (7.4) as self-sufficiency; a State is not a mere aggregate of persons; it is a union of them sufficient for the purposes of life (7.8). The early Roman jurists speak little of sovereignty. But later, with the belief in the existence of an empire entitled to universal sway, an absolutist theory of sovereignty was developed in the writings of jurists.

Among the theories prevalent in the middle ages was one that mankind formed a unity, with the pope and the emperor at the head of it: the universal church and the universal emperor ruled the world. (Rehm, Geschichte der Rechtswissenschaft, p. 198). When the power of the emperor was weakened, and the idea of a universal ruler was gone, a new test of sovereignty was applied -that of external independence; the true sovereign States were universitates superiorem non recognoscentes. There were times and countries in the middle ages in which the collective power of the community was small: many of the great corporations were virtually autonomous; the central authority was weak; the matters as to which it could count upon universal obedience were few. In such circumstances the conception of sovereignty was imperfect. The modern theory is first clearly stated in Jean Bodin's book On the Commonwealth (French ed., 1576; Latin version, 1586). He writes thus: "Respublica est familiarum rerumque inter ipsas communium, summa potestate ac ratione moderata multitudo." His theory, which corresponded to the France of Louis XI., was a theory of despotism.

One favourite theory was that sovereignty originated in a social contract. Hobbes, in his Leviathan expounded his notion of an agreement by which absolute power was irrevocably transferred to the ruler. Rousseau assumes his famous pacte social, the terms of which are: "Chacun de nous met en commun sa personne et toute sa puissance sous la suprême direction de la volonté générale; et nous reçevons encore chaque membre comme partie indivisible de tout" (Du Contrat social, r. c. 6).

Among the different senses in which "sovereign" has been used are the following:-

a. "Sovereign" may be titular—the king in Great Britain.

b. The legal sovereign: the person or persons who, according to the law of the land, legislate or administer the government.

c. The political or constitutional sovereign: the body of per-

April 19, 1836. She brought up her grandson, Charles, duc de sons in whom the actual power at any moment or ultimately Morny, her son's natural son by Queen Hortense. sometimes this is designated "the collective sovereignty."

d. Sovereignty is also used in a wider sense, as the equivalent of the power of the whole nation or society (Gierke, 3. 568).

The distinction between real and nominal sovereignty was familiar to mediaeval writers, who recognized a double sovereignty, and distinguished between (1) the real or practical sovereignty resident in the people, and (2) the personal sovereignty of the ruler (Adolf Dock, Der Souveranitätsbegriff, etc., p. 13).

Sometimes sovereignty is defined as the organized or general will of the community. "Sovereignty resides in the community"

(Woodrow Wilson).

This was the belief in the French Revolution. "Sachez que vous êtes rois et plus des rois," said a revolutionary orator cited by Taine. It was the language of the founders of the American constitution and contemporary political writers.

The same theory assumes a more subtle form, especially in the writings of Hegelians. Sovereignty is with them a term descriptive of the real will of the community, which is not neces-

sarily that of the majority.

Sovereignty is used in a further sense when Plato and Aristotle speak of the sovereignty of the laws (Laws, 4. 715; Politics, 4. 4; 3. 15). Thus Plato remarks: "I see that the State in which the law is above the rulers, and the rulers are the inferiors of the law, has salvation." (See also Gierke, Genossenschaftsrecht, 3. 8.) Even in mediaeval writers, such as Bracton, is found the notion that the king is subject to the laws (J. N. Figgis, The Divine Right of Kings, p. 13). We find the same expressed by many German jurists (Gierke iii., x.). In Der Souveranitätsbegriff im Bodin, etc., by Adolf Dock [1897] p. 6, and in *La Conception juridique de l'état*, by Combothecra, p. 90. There are many definitions—some ideal-of sovereignty.

Half Sovereign States.—The phrase half sovereign States was invented by J. J. Moser to describe States possessing some of the attributes of sovereignty. Under this class are grouped very

diverse communities.

Feudalism had terms to express the varieties of fiefs which existed under it; modern international law has no generallyaccepted terminology for the still greater variety of States which now exist. These varieties tend to multiply, and it is difficult to reduce them all to a few types. The theory that States are equal, and possess all the attributes of sovereignty, was never true. It is still more at variance with the facts in these days when a few great States predominate, and when the contact of western States with African and Asiatic States or communities gives rise to relations of dependence falling short of conquest. We have:

1. States which have complete independence, complete autonomy, external and internal, and which are recognized in inter-

national law as sovereign States.

2. States which have complete external independence, but are more or less subject permanently to other States as to their internal affairs. Of this class there are now few examples.

States which enjoy complete autonomy as to internal affairs, but which are more or less subject to other States as to

foreign relations. These are some examples:a. Protectorates and Suzerainties (qq.v.).

b. The unions between a superior and inferior State, e.g., the relations of the various States to the old Holy Roman empire; the relations of the Ottoman Porte to its Christian provinces. In the middle ages the question was often mooted whether States subject to feudal superiors, or the States forming the empire, were sovereign. Grotius (1. 1. ch. 3, 23, 2), holds that the nexus feudalis is consistent with summum imperium.

4. States which have, by treaty or otherwise, parted with some portion of their sovereignty and formed new political units: what Herbert Spencer calls "compound political heads." For years one of the burning questions in the politics of the United States was the question whether the individual States of the Union remained

sovereign.

5. Another division includes anomalous cases, such as Egypt, until August 1936, in which one Government administers a country as to which another State retains certain powers.

6. The territories governed or administered by chartered companies form a class by themselves. Nominally such companies are the delegates of some States; in reality they act as if they were true sovereigns.

7. Two other classes may be mentioned: (a) cases of real minon between States, as formerly between Austria and Hungary; (b) personal unions, distinguished from the above-named forms—e.g., the union of Great Britain and Hanover.

8. A small group consists of instances of condominium or arrangements similar thereto; e.g., the arrangements as to the Samoa islands from 1889 to 1899.

According to modern usage the appellation "sovereign State" belongs only to States of considerable size and population exercising without control the usual powers of a State, e.g., able to declare peace or war.

Colonies.—It is sometimes suggested that self-governing colonies are to be regarded as true States. Undoubtedly some of them can no longer be regarded as colonies in the old sense The self-governing colonies forming part of the "multicellular British State," as F. W. Maitland describes it (Political Theories of the Middle Ages, p. x.), have an essentially "state-like character." If Liberia is a State, the same may surely be said of Canada.

With the creation of the League of Nations, however, the theory of sovereignty has become still more academic and impracticable. India and the Dominions are equal members with Great Britain of the League. As a member of the League the sovereignty of Great Britain is limited to the same extent as that of Ireland or any other member. And there are at least a dozen States in Europe members of the League, which enjoy, both in fact and in law, less independence than the dominions. The old distinction between sovereign and non-sovereign States has ceased to exist. A sovereign State is now obsolete. Even the United States is not absolutely sovereign. There is no State more rigorously bound by treaties. Nevertheless a new life has been given to the doctrine by the appeal of the succession States in central Europe to the League in their attempts to coerce their minorities to respect their sovereignty. The only valid sovereignty is that of the rule of law.

Many attempts have been made to enumerate the attributes of sovereignty, i.e., the regalia, prerogatives, etc, as they were called. For example, Bodin gives a list of the properties of majestas or sovereignty: (a) "Legem universis, etc., singulis civibus dare posse; (b) bellum indicere aut pacem inire; (c) to appoint and change magistrates; (d) power of final appeal; (e) power of pardon; (f) raising revenue; (g) coining money" (De republica, vol. i. ch. 10). Bluntschli (Allgemeine Staatslehre, i. 575) enumerates these attributes: (a) right of recognition of majestas; (b) independence; (c) power to determine constitution; (d) right of legislation; (e) action through deposed organs; (f) irresponsibility. These enumerations are open to the objection that they merely describe the action of the State at a particular time or indicate a theory of what an ideal State should be. See PROTECTORATE, SPHERES OF INFLUENCE, SUZERAINTY.

BIBLIOGRAFHY.—The literature of the subject is immense; every book on political science, from the Republic of Plato and the Politics of Aristotle, has dealt with or touched sovereignty. A few of the chief modern works are: J. C. Bluntschil, Allgemeine Staatslehre (Munich, 1832); J. Austin, Lectures on Jurisprindence (3rd ed., 1869); H. Maine, "Minute on the Käthiäwär States," Life and Speeches (1869); H. Maine, "Mistory of Institutions (1875); R. von Mohl, Encyslopädie der Staatswissenschaften (and ed., Tübingen, 1872); P. Laband, Staatercht des deutschen Rieches (Freiburg-im-Breisgau and Tübingen, 1876); G. Meyer, Lehrbuch des deutschen Staatsrechts (Leipzig, 1878); G. Gierke, Johannes Althains (Breslau 1880) and Das deutsche Genossenschaftsrecht (1863–81); K. Gareis, Allgemeines Staatsrecht (1883); G. Jellinek, Die Lehre von den Staatsverbindungen (1882) and Über Staatsfragmente (1896); H. Rosin, Souveranitätstaat (1883); G. Salomon, L'Occupation des Territoires sans Maitres (1889); T. M. Cooley, Constitution (1885, 8th ed. 1915); C. Salomon, L'Occupation des Territoires sans Maitres (1889); T. M. Cooley, Constitution and Limitations (6th ed. 1890); J. B. Westerkamp, Staatenbund und Bundestsaat (Leipzig, 1892); J. R. Green, Works (1892); W. W. Fowler, City State of the Greeks and Romans (1893); I. Clauss, Die Lehre von den Staatsdienstbarkeiten (1894); K. Bornhak, Einsettige Abhängigkeitsverhälbnisse unier den Modernen Staatsen (1896); W. W. Willoughby, The Nature of the State (1890); X. Combothecta, La Conception

juridique de l'état (1899); H. Rehm, Allgemeine Staatslehre (1899); F. H. Giddings, Principles of Sociology (3rd ed., 1899); J. W. Burgess, Political Science and Constitutional Law (Boston, 1899); C. E. Merriam, History of the Theory of Sovereignty Since Rousseau (1000); Bryce, Studies in History and Jurisprudence (2. Essay x. 1901); J. B. Moore, Digest of International Law (1906), vol. i., ch. xviii. seq., and "Notes on Sovereignty, 'American Journal of International Law, vol. I. (1907); W. B. Keith, Responsible Government in the Colonies (1906); T. Batty, International Law (1909); H. H. L. Bellot, "The Rule of Law," in Quarterly Review (April, 1926); H. Goitein, "Some Problems of Sovereignty," in Publications of the Grotius Society, vol. XIII. (1938).

SOWER, CHRISTOPHER (1693-1758), printer and publisher, was born at Laasphe, Ger., and emigrated to Pennsylvania in 1724 with his wife and small son Christopher (1721-84). Sower worked first as a tailor, then took up farming and later bought six acres of land in Germantown, where he settled and built a large house. There, in 1738, he set up a print shop to become the first German printer and publisher in the American colonies. It is not known where he secured his training or the equipment he used-the press, the type, etc. He made his own ink and it is possible that he cast his own type, but the better fonts he used were imported from the Frankfurt foundry of Heinrich Luther. In 1744, it is believed, he also built a paper mill. Most of the Sower publications dealt with religious or educational subjects. The first to bear the Sower imprint swas Eine Ernstliche Ermahnung, an Junge und Alte (1738), followed by the first issue of his almanac (1739). In 1739 he also issued his first complete book, a collection of hymns, and the first number of the newspaper Der Hoch-Deutsch Pensylvanische Geschicht-Schreiber. Like the almanac, the newspaper continued to appear until 1777. The two publications were available in all the colonies and made Sower and his son persons of note in the German communities of Pennsylvania and Maryland. Best known of Sower's publishing efforts was the Biblia; Das ist, Die Heilige Schrift Altes und Neues Testaments, nach der Deutschen Übersetzung D. Martin Luthers (1743), the second edition of the Bible to appear in America. Two later editions were published by his son Christopher, in 1763 and 1776. The first English publication carrying Sower's imprint was Extract from the Laws of William Penn (1740). As a popular journalist Sower was outspoken in his opposition to slavery and war. His practical knowledge of contemporary handicrafts and his social zeal brought him a considerable audience and influence in his time. His son Christopher had been trained very thoroughly, and at Sower's death in 1758 was well qualified to inherit the Sower press.

SOWERBY, JAMES (1757-1832), English natural-history artist, was born in London on March 21, 1757. He became a student at the Royal academy, and subsequently taught drawing, but turned to the illustration of botanical and conchological works; and published English Botany, 36 vol. (1790-1814), and British Mineralogy, 5 vol. (1804-17). He planned and partly carried out The Mineral Conchology of Great Britain, 7 vol. (1812-46), concluded after his death by his sons.

SOWING. The scattering or depositing of seed on or in the ground so that it may grow has been practised from prehistoric to modern times. Broadcasting by hand, the most primitive method, has persisted because machinery cannot be used on newly cleared, rough or stony land or on very small fields. Even sowing requires considerable skill and experience; and, after the seed is cast, it must then be covered. Primitive agriculturists also used a dibbling stick to regulate the spacing and distribution of seed, but the hand labour entailed was still tedious. In the early 17th century, Hugh Plat and Gabriel Plattes described dibblers having metal pins to make holes and a seed-dropping device. Father Francesco Lana-Terzi, a Jesuit of Lombardy, designed a dibbler-type seeding machine in 1670. Although impracticable for sowing, dibblers were part of the average farmer's equipment until 1850.

The next improvement over hand sowing was the development of broadcast seeders. The simplest was a knapsack seeder carried by the operator who turned a hand crank geared to a distributor wheel whose vanes scattered the seed over a wide swath. Another seeder, attached to the end gate of a wagon, was similar in design but used chain drive in place of the hand crank. Primarily de-

signed for grass and clover seed, the wheelbarrow seeder was adapted for distributing grain or commercial fertilizer. Its 10–16 ft. hopper had an oscillating rope or chain in the bottom to control the rate of seeding through the outlets. The modern 2-wheel horse-drawn machine sows all kinds of seed and may be equipped with hoe-type coverers or combined with a cultivator to sow and cover simultaneously.

By contrast the evolution of the grain drill has a long history. The prototype of the modern drill is found on a cylinder seal from Tell Asmar (c. 2,000 B.C.). A later clay tablet (c. 1376 B.C.) clearly shows that the Babylonian drill was merely a rude moldboard plow with a seed pipe inserted behind the plow point. The Assyrians used a similar drill in the 7th century B.C. (Hugo Gressman, Altorientalische Bilden zum Alten Testament, 1927).

The long hiatus in the history of drilling from ancient to modern times ended with the inventon of a revolving seed-dropping mechanism by Tadeo Cavellini of Bologna in 1580 A.D., but no details concerning it are known. A widely publicized drill, invented by Joseph Locatelli of Carinthia, Austria, was demonstrated near Wien in 1662. He used a rotating drum with four rows of brass spoons to catch the seed and drop it into funnels. There were no seed pipes and an ordinary plow served as a furrow opener.

John Worlidge of England described a drill with rudimentary force feed and seed pipes (Systema Agriculturae, 1669), but there is no evidence that it was ever built. He even suggested using a fertilizer attachment. About 1701, Jethro Tull invented the first machine that would open a furrow, sow and cover in one operation. His 1733 model had three hoes, or coulters, with seed cavities behind them, a seeding device and pointed shovels for covering. The practice of drilling spread slowly, however, until 1783 when James Cooke brought out a model embodying spoon feed, seed pipes, drill shoes and spike-shaped shovels that laid the foundation for modern European drills.

In the U.S. Eliakim Spooner patented a seeder in 1799, but not until Moses and Samuel Pennock of Kennett Square, Pa, patented their hoe drill in 1841 were any noteworthy U.S. models produced. Their drill, equipped with seven hoes 9 in. apart, planted all kinds of field crops. The numerous drills patented after 1850 diverged still farther from the English by using the force feed originally proposed by Worlidge and different furrow openers. The opening of the great wheat areas caused drilling to be widely accepted, and, by 1890, disk drills for "stubbling in" directly without preparation of a seedbed were replacing shoe drills.

Current European drills are characterized by fore-steerage, cup feed and coulters; and the U.S., by pole attachment, force feed and disk furrow openers. Combined grain and fertilizer drills hitched on spring-tine cultivators, with harrows trailing behind, prepare and plant about 80-100 ac. per day, a far cry from hand sowing. Special planters have been developed in the U.S. for corn, cotton and potatoes. The check-row corn planter sows a field in a checkerboard pattern to permit cross cultivation between hills. Buttons on a guide wire stretched across the field trip the seeding mechanism as they pass through the machine. Special attachments deposit fertilizer on each side of the seed. Modern cotton planters are similar to corn planters and can be used for most field row crops because they have interchangeable seed plates. Lister planters designed to break furrows, plant and cover are used for both corn and cotton. Semimechanical potato planters still depend on the operator to feed the seed to the cups and to supply misses in the seed plate. Transplanting machines for tobacco, cabbage, tomatoes, celery, sweet potatoes, etc., simultaneously set, water and fertilize the young plants, making it possible to cover 3-4 ac. per day.

SOYBEAN, also known in some countries as the soja bean and the soya bean, is a leguminous plant native to south-

eastern Asia. It has been cultivated in China and Japan since long before written records were kept, and from the standpoint of uses and value is the most important legume now grown in those countries. Although limited acreages are grown in Italy, France, southern Russia, Rumania, Netherlands Indies, South Africa and in a few countries of South America, its culture at present is largely confined to China, Manchuria, Japan, Chosen (Korea) and the United States. It is also more or less important in India, Indo China and the Malayan islands. Although first introduced into the United States in 1804, the soybean has become important only during the last 20 years. Only 8 varieties were grown in 1808. whereas at present more than 100 varieties are handled by growers and seedsmen. Previous to 1917, the soybean acreage was less than 500,000, but by 1939 it had increased to more than 8,000,000. The soybean can be grown in any climate suitable to maize or cotton, and the crop is now grown generally over the eastern half of the United States. Recent increases in acreage have been most marked in the maize belt and some of the Southern States. Introduction and breeding of improved varieties have extended the culture of the crop far beyond what were first considered its limits of profitable production, and it is destined to become a crop of great economic importance in the United States. Its principal uses are hay, pasture, silage, oil and oil meal, and human food (see SOYBEAN OIL). It can be used advantageously, either as a seed crop or a forage crop, in many systems of rotation; also as a catch crop where new seedings of grass or clover have failed. In combinations with other crops, such as corn, cow-peas, Sudan grass or sorghums, it furnishes a well-balanced ration for livestock, a large yield and a great variety of forage,

Cultivation.—The growing of soybeans is easy when ordinary precautions are followed in preparing the soil and selecting suitable varieties. Where they have not been grown previously it is advisable to inoculate the soil with soybean bacteria. The use of fertilizer is recommended in sandy soil or in soils of low fertility. Seeding is usually done with an ordinary grain drill, the rows being spaced far enough apart to allow for cultivation when the crop is grown for seed. Seeding is usually done in the Corn Belt States with the grain drill, the rows in close drills, and the fields cultivated with the harrow, weeder or rotary hoe. In the Southern States the beans are planted in rows 3 to 6 feet apart. Harvesting the seed is accomplished with the combine. (L. S. R.; X.)

SOYBEAN OIL. An oil obtained from the seeds of the leguminous plant, Soja max (L.) Piper, one of the oldest staple crops of the Far East, where for centuries both the oil and expressed cake have been used as food. Introduced about 1919 in Mid-western U.S., its cultivation now requires over 8,000,000 acres. The beans, containing 18% to 20% of oil, yield by expression in American expellers about 15%; somewhat less in hydraulic presses (see Coco-NUT OIL AND CAKE), or Chinese wedge presses. Hydrocarbon solvent extraction, which leaves about 1% of oil in the cake, is preferred in Europe, but is of secondary importance in America. The meal is high in proteins (41% to 50%), which are similar to the proteins of milk. Valuable for livestock, soybean oil meal is also prepared for human food, mostly in sausage and bakery products in the form of flour; in the Orient soy sauce and vegetable cheese are made from whole soybeans. The oil contains 84% to 87% of unsaturated glycerides, and is classed as a drying oil; for paints, lead and manganese driers are used, and for varnishes, cobalt; for salad oil, alkali refining, bleaching by fuller's earth, and steam deodorization are essential. More than half of the refined oil is hydrogenated and consumed in the manufacturing of shortening and margarine (see Hydrogenation). World production of soybeans for 1937 amounted to 12,500,000 long tons. Leading producers of soybean oil were U.S., 143,750 tons (1938); Germany, 115,584 tons (1938); Manchuria, 62,503 tons (M. M. D.)

SÓZOMEN, the name of a famous 5th-century church historian. Hermias Salamanes (Salaminius) Sozomenus (c. 400-443) came of a wealthy family of Palestine. He tells us that he was brought up under monkish influences. After studying law in Beirūt he settled down as an advocate in Constantinople, where hewrote his Ekchnotaarus Toropla about the year 440. The nine

books begin with Constantine (323) and come down to the death of Honorius (423). The work, dedicated to Theodosius II., has reached us only in a mutilated condition, at least half a book being wanting. It is a plagiarism of the ecclesiastical historian Socrates (q.v.), but Sozomen has referred to the principal sources used by Socrates (Rufinus, Eusebius, Athanasius, Sabinus, the collections of epistles, Palladius), and has not unfrequently supplemented Socrates from them. The whole of the ninth book is drawn from Olympiodorus. Sozomen wished to present a picture in which monasticism should be brought into still stronger prominence.

Sozomen also wrote an Epitome of History from the Ascension of Christ to the defeat of Licinius (323) which is not now extant. (See his

History, i. 1.)

For bibliography see the article on the church historian, Socrates. For bibliography see the article on the church historian, Socrares. Most of the editions and discussions named there cover Sozomen as well (the volume of Hussey's edition containing Sozomen appeared in 1860). The latest English translation, revised by Hartranti, is published in the Nicene and Post-Nicene Pathers, and series, vol. it. n addition see Nolte in the Thibing. Quartalschir. (1861), p. 417, spq.; C. de Boor, "Zur Kenntniss der Handschriften der Griech, Kirchenisther." in Zeitschrift fur Krichengeschichte, vi. 478, sqq.; Sarratin, "De Sozomeni historia num integra sit," in the Commentationes philologae jenenses, i. 165 sqq.; Rosenstein, "Krit. Untersuchungen über d. Verhaltnus zwischen Olympiodor, Zosimus und Sozomen" in Karock, z. deutschen Gesch. vol. 1: Bailfeld, "Sozomene" in men," in Forsch. z. deutschen Gesch., vol. i.; Batiffol, "Sozomène et Sabinos," in Byzant. Zeitschr. vii. 265 sqq.

SPA, a town in the province of Liège, Belgium, less than 20 mi. S.E. of Liège, famous for mineral springs first discovered in 1326. The springs have given the common name of "spa" to such resorts. The town is 850 ft. above sea level. In the 18th century it was the most fashionable resort in Europe for the medicinal use of such waters. In 1807 much of the town was burned down, and the principal buildings, the Casino and the Pouhon, are quite modern. Spa in ordinary times attracts about 20,000 visitors

annually. Pop. (1947) 9,002. **SPA, CONFERENCE OF** (July 5-16, 1920). This was the first occasion after the World War of 1914-18 on which the heads of the German and Allied Governments negotiated on a formal footing of equality. The crucial questions at issue were the execution of the disarmament clauses and the coal delivery clauses of the Treaty of Versailles, and in both cases the Germans were compelled to sign protocols dictated by the Allies under threat of military sanctions which were set out in the documents, and included an eventual Allied occupation of the Ruhr basin.

A German proposal for the general settlement of the reparation problem was rejected, but no general Allied counter-proposal was put forward. An inter-Allied agreement was made for the allocation of prospective German payments, an agreement which has since been modified in detail, but which still governs the situation. It was provided that France should receive 52% of sums obtained from Germany, the British Empire 22%, Italy 10% and Belgium 8%, while the remaining 8% was to be divided between the other Allied Powers. By a subsequent agreement among the several members of the British Commonwealth 86.85% of the British Empire's share was allocated to Great Britain. Another article in the Spa Agreement provided for the allocation of reparation payments from Austria, Bulgaria and Hungary, and "cost of liberation" payments from Italy, Czechoslovakia, Rumania and Yugoslavia.

At this conference the Supreme Council also came to an agreement with Germany for the trial of war criminals.

SPACE-TIME. The Theory of Relativity has brought about a fundamental change in the scientific conception of space and time, described in a famous saying of Minkowski-"From henceforth space in itself and time in itself sink to mere shadows, and only a kind of union of the two preserves an independent existence." This union, called "space-time," is the subject of the present article. As the conceptions are of considerable difficulty, most readers will probably find it best to read first the article RELATIVITY for a more elementary introduction to the subject.

All our thoughts and concepts are called up by sense-experiences and have a meaning only in reference to these sense-experiences. On the other hand, however, they are products of the spontaneous activity of our minds; they are thus in no wise logical consequences of the contents of these sense-experiences. If, therefore, we wish to grasp the essence of a complex of abstract notions we must for the one part investigate the mutual relationships between the concepts and the assertions made about them; for the other, we must investigate how they are related to the experiences.

So far as the way is concerned in which concepts are connected with one another and with the experiences there is no difference of principle between the concept-systems of science and those of daily life. The concept-systems of science have grown out of those of daily life and have been modified and completed according to the objects and purposes of the science in question.

The more universal a concept is the more frequently it enters into our thinking; and the more indirect its relation to senseexperience, the more difficult it is for us to comprehend its meaning; this is particularly the case with pre-scientific concepts that we have been accustomed to use since childhood. Consider the concepts referred to in the words "where," "when," "why," "being," to the elucidation of which innumerable volumes of philosophy have been devoted. We fare no better in our speculations than a fish which should strive to become clear as to what

In the present article we are concerned with the meaning of "where," that is, of space. It appears that there is no quality contained in our individual primitive sense-experiences that may be designated as spatial. Rather, what is spatial appears to be a sort of order of the material objects of experience. The concept "material object" must therefore be available if concepts concerning space are to be possible. It is the logically primary concept. This is easily seen if we analyse the spatial concepts for example, "next to," "touch," and so forth, that is, if we strive to become aware of their equivalents in experience. The concept "object" is a means of taking into account the persistence in time or the continuity, respectively, of certain groups of experience-complexes. The existence of objects is thus of a conceptual nature, and the meaning of the concepts of objects depends wholly on their being connected (intuitively) with groups of elementary sense-experiences. This connection is the basis of the illusion which makes primitive experience appear to inform us directly about the relation of material bodies (which exist, after all, only in so far as they are thought).

In the sense thus indicated we have (the indirect) experience of the contact of two bodies. We need do no more than call attention to this, as we gain nothing for our present purpose by singling out the individual experiences to which this assertion alludes. Many bodies can be brought into permanent contact with one another in manifold ways. We speak in this sense of the position-relationships of bodies (Lagenbeziehungen). The general laws of such position-relationships are essentially the concern of geometry. This holds, at least, if we do not wish to restrict ourselves to regarding the propositions that occur in this branch of knowledge merely as relationships between empty words that have been set up according to certain principles.

Pre-scientific Thought .- Now, what is the meaning of the concept "space" which we also encounter in pre-scientific thought? The concept of space in pre-scientific thought is characterized by the sentence: "we can think away things but not the space which they occupy." It is as if, without having had experience of any sort, we had a concept, nay even a presentation, of space and as if we ordered our sense-experiences with the help of this concept. present a priori. On the other hand, space appears as a physical reality, as a thing which exists independently of our thought, like material objects. Under the influence of this view of space the fundamental concepts of geometry: the point, the straight line, the plane, were even regarded as having a self-evident character. The fundamental principles that deal with these configurations were regarded as being necessarily valid and as having at the same time an objective content. No scruples were felt about ascribing an objective meaning to such statements as "three empirically given bodies (practically infinitely small) lie on one straight line," without demanding a physical definition for such an assertion. This blind faith in evidence and in the immediately real meaning of the concepts and propositions of geometry became uncertain only after non-Euclidean geometry had been introduced.

Reference to the Earth,-If we start from the view that all spatial concepts are related to contact-experiences of solid bodies, it is easy to understand how the concept "space" originated, namely, how a thing independent of bodies and yet embodying their position possibilities (Lagerungsmöglichkeiten) was posited. If we have a system of bodies in contact and at rest relatively to one another, some can be replaced by others. This property of allowing substitution is interpreted as "available space." Space denotes the property in virtue of which rigid bodies can occupy different positions. The view that space is something with a unity of its own is perhaps due to the circumstance that in pre-scientific thought all positions of bodies were referred to one body (reference body), namely the earth. In scientific thought the earth is represented by the co-ordinate system. The assertion that it would be possible to place an unlimited number of bodies next to one another denotes that space is infinite. In pre-scientific thought the concepts "space" and "time" and "body of reference" are scarcely differentiated at all. A place of point in space is always taken to mean a material point on a body of reference.

Euclidean Geometry.-If we consider Euclidean geometry we Searly discern that it refers to the laws regulating the positions of rigid bodies. It turns to account the ingenious thought of tracing back all relations concerning bodies and their relative positions to the very simple concept "distance" (Strecke). Distance denotes a rigid body on which two material points (marks) have been specified. The concept of the equality of distances (and angles) refers to experiments involving coincidences; the same remarks apply to the theorems on congruence. Now, Euclidean geometry, in the form in which it has been handed down to us from Euclid, uses the fundamental concepts "straight line" and "plane" which do not appear to correspond, or at any rate, not so directly, with experiences concerning the position of rigid bodies. (On this it must be remarked that the concept of the straight line may be reduced to that of the distance. A hint of this is contained in the theorem; "the straight line is the shortest connection between two points." This theorem served well as a definition of the straight line, although the definition played no part in the logical texture of the deductions.) Moreover, geometricians were less concerned with bringing out the relation of their fundamental concepts to experience than with deducing logically the geometrical propositions from a few axioms enunciated at the outset.

Let us outline briefly how perhaps the basis of Euclidean geometry may be gained from the concepts of distance. We start from the equality of distances (axiom of the equality of distances). Suppose that of two unequal distances one is always greater than the other. The same axioms are to hold for the inequality of distances as hold for the inequality of numbers. Three distances as hold for the inequality of numbers. Three distances  $\overline{AB'}$ ,  $\overline{BC'}$ ,  $\overline{CA'}$  may, if CA' be suitably chosen, have their marks BB', CC', AA' superposed on one another in such a way that a triangle ABC results. The distance CA' has an upper limit for which this construction is still just possible. The points A, (BB') and C then lie in a "straight line" (definition). This leads to the concepts: producing a distance by an amount equal to itself; dividing a distance into equal parts; expressing a distance in terms of a number by means of a measuring-rod (definition of the space-interval between two points).

When the concept of the interval between two points or the length of a distance has been gained in this way we require only the following axiom (Pythagoras' theorem) in order to arrive at Euclidean geometry analytically. To every point of space (body of reference) three numbers (co-ordinates) x, y, z may be assigned—and conversely—in such a way that for each pair of points A  $(x_1, y_1, z_1)$  and B  $(x_2, y_2, z_2)$  the theorem holds:

neasure-number  $AB = \sqrt{(x_2-x_1)^2+(y_2-y_1)^2+(z_2-z_1)^2}$ .

All further concepts and propositions of Euclidean geometry can then be built up purely logically on this basis, in particular also the propositions about the straight line and the plane. These remarks are not, of course, intended to replace the strictly

axiomatic construction of Euclidean geometry. We merely wish to indicate plausibly how all conceptions of geometry may be traced back to that of distance. We might equally well have epitomised the whole basis of Euclidean geometry in the last theorem above. The relation to the foundations of experience would then be furnished by means of a supplementary theorem. The co-ordinate may and must be chosen so that two pairs of points separated by equal intervals, as calculated by the help of Pythagoras' theorem, may be made to coincide with one and the same suitably chosen distance (on a solid). The concepts and propositions of Euclidean geometry may be derived from Pythagoras' proposition without the introduction of rigid bodies; but these concepts and propositions would not then have contents that could be tested. They are not "true" propositions but only logically correct propositions fo purely formal content.

Difficulties.—A serious difficulty is encountered in the above represented interpretation of geometry in that the rigid—body of experience does not correspond exactly with the geometrical body. There are no absolutely definite marks and, moreover, temperature, pressure and other circumstances modify the laws relating to position. It is also to be recollected that the structural constituents of matter (such as atom and electron, q.v.) assumed by physics are not in principle commensurate with rigid bodies, but that nevertheless the concepts of geometry are applied to them and to their parts. For this reason consistent thinkers have been disinclined to allow real contents of facts (reale Taisachenbestände) to correspond to geometry alone. They considered it preferable to allow the content of experience (Erjahrungsbestände) to correspond to geometry and physics conjointly.

This view is certainly less open to attack than the one represented above; as opposed to the atomic theory it is the only one that can be consistently carried through. Nevertheless it would not be advisable to give up the first view, from which geometry derives its origin. This connection is essentially founded on the belief that the ideal rigid body is an abstraction that is well

rooted in the laws of nature.

Foundations of Geometry.—We come now to the question: what is a priori certain or necessary, respectively in geometry (doctrine of space) or its foundations? Formerly we thought everything; nowadays we think—nothing. Already the distance-concept is logically arbitrary; there need be no things that correspond to it, even approximately. Something similar may be said of the concepts straight line, plane, of three-dimensionality and of the validity of Pythagoras' theorem. Even the continuum-doctrine is in no wise given with the nature of human thought, so that from the epistemological point of view no greater authority attaches to the purely topological relations than to the others.

Earlier Physical Concepts.—We have yet to deal with those modifications in the space-concept which have accompanied the advent of the theory of relativity. For this purpose we must consider the space-concept of the earlier physics from a point of view different from that above. If we apply the theorem of Pythagoras to infinitely near points, it reads

 $ds^2 = dx^2 + dy^2 + dz^2$ ,

where ds denotes the measurable interval between them. For an empirically-given ds the co-ordinate system is not yet fully determined for every combination of points by this equation. Besides being translated, a co-ordinate system may also be rotated. This signifies analytically: the relations of Euclidean geometry are covariant with respect to linear orthogonal transformations of the co-ordinates.

In applying Euclidean geometry to pre-relativistic mechanics a further indeterminateness enters through the choice of the coordinate system: the state of motion of the co-ordinate system is arbitrary to a certain degree, namely, in that substitutions of the co-ordinates of the form x'=x-vt

y' = y z' = z

also appear possible. On the other hand, earlier mechanics did

not allow co-ordinate systems to be applied of which the states sum is to be taken over the indices for all combinations 11, 12, of motion were different from those expressed in these equations. In this sense we speak of "inertial systems." In these favouredinertial systems we are confronted with a new property of space so far as geometrical relations are concerned. Regarded more accurately, this is not a property of space alone but of the fourdimensional continuum consisting of time and space conjointly.

Appearance of Time.—At this point time enters explicitly into our discussion for the first time. In their applications space (place) and time always occur together. Every event that happens in the world is determined by the space-co-ordinates x, y, z, and the time-co-ordinate t. Thus the physical description was four-dimensional right from the beginning. But this four-dimensional continuum seemed to resolve itself into the three-dimensional continuum of space and the one-dimensional continuum of time. This apparent resolution owed its origin to the illusion that the meaning of the concept "simultaneity" is self-evident. and this illusion arises from the fact that we receive news of near events almost instantaneously owing to the agency of light.

This faith in the absolute significance of simultaneity was destroyed by the law regulating the propagation of light in empty space or, respectively, by the Maxwell-Lorentz electro-dynamics. Two infinitely near points can be connected by means of a lightsignal if the relation

$$ds^2 = c^2 dt^2 - dx^2 - dy^2 - dz^2 = 0$$

holds for them. It further follows that ds has a value which, for arbitrarily chosen infinitely near space-time points, is independent of the particular inertial system selected. In agreement with this we find that for passing from one inertial system to another, linear equations of transformation hold which do not in general leave the time-values of the events unchanged. It thus became manifest that the four-dimensional continuum of space cannot be split up into a time-continuum and a space-continuum except in an arbitrary way. This invariant quantity ds may be measured by means of measuring-rods and clocks.

Four-dimensional Geometry.—On the invariant ds a fourdimensional geometry may be built up which is in a large measure analogous to Euclidean geometry in three dimensions. In this way physics becomes a sort of statics in a four-dimensional continuum. Apart from the difference in the number of dimensions the latter continuum is distinguished from that of Euclidean geometry in that ds<sup>2</sup> may be greater or less than zero. Corresponding to this we differentiate between time-like and space-like line-elements. The boundary between them is marked out by the element of the "light-cone"  $ds^2=0$  which starts out from every point. If we consider only elements which belong to the same time-value, we have

$$-ds^2 = dx^2 + dv^2 + dz^2$$
.

These elements ds may have real counterparts in distances at rest and, as before, Euclidean geometry holds for these elements. Effect of Relativity, Special and General.-This is the

modification which the doctrine of space and time has undergone through the restricted theory of relativity. The doctrine of space has been still further modified by the general theory of relativity, because this theory denies that the three-dimensional spatial section of the space-time continuum is Euclidean in character. Therefore it asserts that Euclidean geometry does not hold for the relative positions of bodies that are continuously in contact.

For the empirical law of the equality of inertial and gravitational mass led us to interpret the state of the continuum, in so far as it manifests itself with reference to a non-inertial system, as a gravitational field and to treat non-inertial systems as equivalent to inertial systems. Referred to such a system, which is connected with the inertial system by a non-linear transformation of the co-ordinates, the metrical invariant ds2 assumes the general form:

$$ds^2 = \sum g_{\mu\nu} dx_\mu dx_\nu,$$

where the gm 's are functions of the co-ordinates and where the

... 44. The variability of the  $g_{\mu\nu}$ 's is equivalent to the existence of a gravitational field. If the gravitational field is sufficiently general it is not possible at all to find an inertial system, that is, a co-ordinate system with reference to which ds2 may be expressed in the simple form given above:

$$ds^2 = c^2 dt^2 - dx^2 - dy^2 - dz^2$$
;

but in this case, too, there is in the infinitesimal neighbourhood of a soace-time point a local system of reference for which the last-mentioned simple form for ds holds This state of the facts leads to a type of geometry which Riemann's genius created more than half a century before the advent of the general theory of relativity of which Riemann divined the high importance for physics.

Riemann's Geometry.-Riemann's geometry of an n-dimensional space bears the same relation to Euclidean geometry of an n-dimensional space as the general geometry of curved surfaces bears to the geometry of the plane. For the infinitesimal neighbourhood of a point on a curved surface there is a local coordinate system in which the distance ds between two infinitely near points is given by the equation

$$ds^2 = dx^2 + dy^2$$
.

For any arbitrary (Gaussian) co-ordinate-system, however, an expression of the form

## $ds^2 = g_{11}dx^2 + 2g_{12}dx_1dx_2 + g_{22}dx_2^2$

holds in a finite region of the curved surface. If the  $g\mu\nu$ 's are given as functions of  $z_1$  and  $z_2$  the surface is then fully determined geometrically. For from this formula we can calculate for every combination of two infinitely near points on the surface the length ds of the minute rod connecting them; and with the help of this formula all networks that can be constructed on the surface with these little rods can be calculated. In particular, the "curvature" at every point of the surface can be calculated; this is the quantity that expresses to what extent and in what way the laws regulating the positions of the minute rods in the immediate vicinity of the point under consid-

eration deviate from those of the geometry of the plane.

This theory of surfaces by Gauss has been extended by Riemann to continua of any arbitrary number of dimensions and has thus paved the way for the general theory of relativity. For it was shown above that corresponding to two infinitely near space-time points there is that corresponding to two infinitely near space-time points there is a number ds which can be obtained by measurement with rigid measuring-rods and clocks (in the case of time-like elements, indeed, with a clock alone). This quantity occurs in the mathematical theory in place of the length of the minute rods in three-dimensional geometry. The curves for which \( \int d \) as has stationary values determine the paths of material points and rays of light in the gravitational field, and the "curvature" of space is dependent on the matter distributed over space.

Just as in Euclidean geometry the space-concept refers to the position-possibilities of rigid bodies, so in the general theory of relativity the space-time-concept refers to the behaviour of rigid bodies tivity the space-time-concept refers to the behaviour or ngid bodies and clocks. The space-time-continuum however differs from the space-continuum in that the laws regulating the behaviour of these objects (clocks and measuring-rods) depend on where they happen to be. The continuum (or the quantities that describe it) enters explicitly into the laws of nature, and conversely these properties of the continuum are determined by physical factors. The relations that connect space and time can no longer be kept distinct from physics proper. Nothing certain is known of what the properties of the space-time-continuum may be as a whole. Through the general theory of relativity, however, the view that the continuum is infinite in its time-like extent but finite in its space-like extent has gained in probability.

#### TIME

The physical time-concept answers to the time-concept of the extra-scientific mind. Now, the latter has its root in the time-order of the experiences of the individual, and this order we must accept as some-thing primarily given. One experiences the moment "'now," or, exed more accurately, the present sense-experience (Sinnen-Erlebnis) combined with the recollection of (earlier) sense-experiences. combined with the recollection of (earner) sense-experiences. That is why the sense-experiences seem to form a series, namely the time-series indicated by "earlier" and "later." The experience-series is thought of as a one-dimensional continuum. Experience-series can repeat themselves and can then be recognized. They can also be repeated inexactly, wherein some events are replaced by others without the character of the repetition becoming lost for us. In this way we form the time-concept as a one-dimensional frame which can be filled to be arrestored to the repetitions becoming the control of the co in by experiences in various ways. The same series of experiences answer to the same subjective time-intervals.

The transition from this "subjective" time (Ich-Zeit) to the time-concept of pre-scientific thought is connected with the formation of ea that there is a real external world independent of the subject. In this sense the (objective) event is made to correspond with the subjective experience. In the same sense there is attributed to the "subjective" time of the experience a "time" of the corresponding "objective" event. In contrast with experiences external events and their order in time claim validity for all subjects.

This process of objectification would encounter no difficulties were the time-order of the experiences corresponding to a series of external events the same for all individuals. In the case of the immediate visual perceptions of our daily lives, this correspondence is exact. That is why the idea that there is an objective time-order became established to an extraordinary extent. In working out the idea of an objective world of external events in greater detail, it was found necessary to make events and experiences depend on each other in a necessary to make events and experiences depend on earn other in a more complicated way This was at first done by means of rules and modes of thought instinctively gained, in which the conception of space plays a particularly prominent part. This process of refinement leads ultimately to natural science.

The measurement of time is effected by means of clocks. A clock is a thing which automatically passes in succession through a (practically) equal series of events (period). The number of periods (clocktime) elapsed serves as a measure of time. The meaning of this defi-nition is at once clear if the event occurs in the immediate vicinity of intended is a concern the event occurs in the inhibition of the clock in space; for all observers then observe the same clock-time simultaneously with the event (by means of the eye) independently of their position Until the theory of cleativity was propounded it was assumed that the conception of simultaneity had an absolute objective

assumed that the conception of simultaneity had an absolute objective meaning also for events separated in space.

This assumption was demolished by the discovery of the law of propagation of light. For if the velocity of light in empty space is to be a quantity that is independent of the choice (or, respectively, of the state of motion) of the inertial system to which it is referred, no absolute meaning can be assigned to the conception of the simultaneity of events that occur at points separated by a distance in space. Rather, a special time must be allocated to every inertial system. If no co-ordinate system (inertial system) is used as a basis of reference there is no sense in asserting that events at different points in space occur simultaneously. It is in consequence of this that space and time are welded together into a uniform four-dimensional continuum. See RELATIVITY.

Recent Developments.-The concepts of space and time which lie at the basis of the Newtonian natural philosophy, and which have provided a general background for the understanding of the external world during the last three centuries, are now known to be untenable, as a result of the progress of theoretical physics in the present

The concepts in question may be said to have originated with Pierre Gassendi (1592-1655), who, opposing Descartes' representation of space as a plenum, revived the doctrines of the ancient atomists of space as a plentum, revived the doctrines of the ancient atomists regarding the void. This implied making a distinction between matter and extension, asserting that while space has extension, matter has solidity as well, and occupies only a part of space, Gassendi's ideas were adopted by Newton, and thus was evolved the portrayal of space and time which became finally established in classical physics. Its fundamental postulate is that all the phenomena of the external world can be described in terms of the location and motion in space of entities, each of which has some degree of persistence and continof entities, each of which has some degree of persistence and continuous identity in time: so that whatever happens, happens in space: space, the stage on which the drama of physics is to be played, is the dominating conception of the whole system. Thus, with Newton, space is regarded as having a positive, objective existence, which is not attached in any way to subjective necessities of the human mind. "Absolute space," he says, "in its own nature, without regard to anything external, remains always similar and immovable," and "All things are placed in space, as regards order of situation." (Principia, Schol. ad Defin.). It is a real entity, subsisting prior to, and independently of, the bodies which it contains: and all events in nature can be represented by movements within it. Every point of space can be represented by movements within it. Every point of space persists throughout an infinite succession of instants of time, and the notion of public simultaneity is valid, with all the implications which it carries in classical physics. In the Gassendi-Newton scheme it is not considered necessary to account for the existence of entities which are permanent over appreciable durations of time, such as particles of matter: these are postulated, and the aim of science is to explain the changing phenomena of the universe in terms of their motions. Persistence of bodies in time, and their displacement in space are the concepts to which everything in the external world is

It was, however, necessary to account for the fact that gravita-tional, optical and electrical influences could be transmitted across donal, optical and electrical inductions could be transmitted across space which was void of ordinary matter: and for this purpose the ether was invented—an invisible medium filling all space, whose stresses and vibrations constituted the influences in question. The effect of this introduction was to endow space with practically all the qualities of an ordinary solid body, except visibility. A meaning could now be attached to the concept of absolute position in space, since

this was interpreted as position relative to points fixed in the ether. The existence of the ether, the Newtonian idea of public simultaneity, and the possibility of a complete separation of space from time, were all rejected after 1905, as a result of the theory of Special Relativity; and the discovery of General Relativity in 1915 made it necessary to abandon also the doctrine of the homogeneity of spacetime. The theory of the Expanding Universe, which was developed about 1930, destroyed still more of the old framework, by showing that the world contains only a finite number of cubic miles, and that this number varies with the time. Very little was left of the Newtonian ideas now, beyond the general understanding that nature could tonian ideas now, beyond the general understanding that nature could be interpreted by the existence and motion of entities in space and time; and this also was destined to perish. In the latter part of the roth century all the optical phenomena then known had been explained by the undulatory theory, i.e., the hypothesis that light consists essentially of waves. Now waves propagated outwards from a source of disturbance have the property of spreading, so that the energy of the disturbance becomes diffused over a progressively larger water. But could not be the control that the control of the latter and the latter and the control of the latter and the latter region; but early in the 20th century it was found (see LIGHT) that in some types of experiment there is no spreading; the luminous energy travels in a compact bundle, as in the old corpuscular theory of light. It was realized eventually that the undulatory and corpuscular theories are, in a sense, both true—light is both a wave and a particle, but this cannot be understood in terms of the classical idea of space, and is incompatible with it.

This conclusion was confirmed in another way, starting from the exploration given by Niels Bohr in 1913 of the emission of spectra. In Bohr's theory, the electrons in an atom move in orbits around the nucleus, like the orbits of the planets around the sun. Sometimes an electron falls from one orbit into another orbit nearer the nucleus, and the energy so lost is radiated outwards as light. (See Atom; QUANTUM MECHANICS; SPECTROSCOPY.) Bohr was, however, unable to explain how the electron moved from the one orbit to the other. At the time this was regarded as an imperfection in his theory, but ultimately it came to be regarded as one of the most valuable of its features; for it introduced the idea of a change which was later shown to be, even in principle, incapable of description in terms of space and time. The electron, in fact, like light, has two aspects, particle and wave, and the same was found to be true of all the ultimate constituents of the universe. It is not possible to assign to them a definite location in space combined with a definite velocity, and they cannot be represented by any picture which is based on classical ideas. At De represented by any picture which is based on classical ideas. At present there is no known way of expressing them except by mathematical formulae; but, as these formulae enable us to predict future events, they are sufficient for the purposes of science. The hope of forming an intuitive notion of what is going on around us has been

The concept of time has also been the subject of fruitful investigations in recent years, the most striking new ideas being those of Edward A. Milne. The system of time-measurement in common use is based on the principle that the angle through which the earth has 10tated on its axis (measured with reference to the fixed stars, whose small proper motions we can for this purpose neglect) in the interval between two events, measures the time elapsed between the events in question: this angular measure being convertible into the ordinary measure in terms of mean solar hours at the rate of 360° to 24 x 2 man of the convertible into the measure in terms of mean solar hours at the rate of 360° to 24 x 2 man of the convertible into the convertible mamical principles, such as pendulum clocks, give indications in accordance with this system, which Milne calls dynamical time. He points out, however, that it is possible to conceive of a totally different system of time-measurement, based not on molar dynamics, but on atomic phenomena. For instance, atoms of radium are continually disintegrating, by the emission of alpha and beta particles, into atoms disintegrating, by the consistent of applies and occasionate of arother radio-active element known as radon; the number of atoms which disintegrate in a given interval of time is a definite fraction of the number of non-disintegrated atoms which were present at the beginning of the interval. Evidently this property will serve for the construction (in principle) of a radio-active clock. Time as measured by radio-active clocks or by other means depending on changes in the atom (such as emission of light of definite frequency) is called the atom (such as emission of light of definite frequency) is called by Milne kinematic time. For phenomena taking place at the present moment, dynamical time and kinematic time keep pace with each other; but over long stretches of time they differ greatly. Measured in dynamical time, the frequency of atomic vibrations is always increasing, so that light reaching us now from distant nebulae, and emitted a long time ago, has a lower frequency than light emitted by similar atoms here and now: and this is Milne's explanation of the red-shift of the spectral lines of the remotest objects in the cosmos. The mathematical relation between the two kinds of time is

 $\tau = t_0 \log \frac{t}{t_0} + t_0$ 

where  $\tau$  is dynamical time, t is kinematic time, and to is the present value of t, i.e., the age of the universe reckoned in t-time from the Creation. Evidently the zero value of t corresponds to an infinite Creation. Evidently the zero value of r corresponds to an immune negative value of r; so that in Milne's theory, whether we say that the Creation took place a finite number of years ago, or is infinitely remote, depends on the arbitrary choice of our scale of time. (E. Wr.)

SPADEFISH (Chaetodipterus faber), a very deep-bodied, of the earth's surface which is included between latitudes 43° almost circular fish of the family Ephippidae, 2 to 3 ft. long, common in Atlantic waters from Massachusetts to Brazil and much prized for food. It has a small mouth, with brushlike teeth. The lateral line follows the humped curve of the body. In colour it is grayish, with four dark bands running from the top of the back down the body. It is also called angelfish.

SPADE GUINEA, the name by which the guinea coined in the reign of George III came to be known. It was so called because the reverse of the coin was designed with a shield pointed at the base after the fashion of a spade. See GUINEA.

SPADINI, ARMANDO (1883-1925), Italian painter, was born in Florence July 19, 1883. Not until the International exhibition at Venice in 1924 where 48 of his paintings were displayed was he assured of a definite place in modern Italian art. In 1010 he went to Rome where he died on March 31, 1925. He painted a number of notable pastoral scenes and a few portraits but his best subjects are domestic scenes.

SPAGHETTI: see MACARONI.

SPAGNA, LO (d. after 1530), the usual designation (because of his Spanish origin) of the Italian painter Giovanni di Pietro, a pupil and assistant of Perugino. Nothing is known of his early life. The chief of his numerous panel paintings are the "Nativity, in the Vatican, and the "Adoration of the Magi," at Berlin. Lo Spagna's frescoes reach a higher standard of merit than his panel pictures. The museum of the Capitol in Rome possesses a very beautiful series of life-sized fresco figures by him, representing Apollo and the nine muses from la Magliana, formerly ascribed to Raphael.

SPAHIS, originally the holders of fiefs in central Asia who yielded personal military service to their superior chief (in Persian sipari, meaning warriors, and synonymous with sepoy). In time the term came to be applied to the soldiery furnished in their own stead. A similar institution existed in Turkey, and the "Spahis" were the light irregular cavalry which from the time of Sultan Murad I (1362) down to the beginning of the 19th century formed the flower of the Turkish army; at one period they are estimated to have numbered 130,000. "Spahis" is the term now applied to certain native cavalry regiments in Algiers and Tunis, officered by Frenchmen.

SPAHLINGER, HENRY (1882-), Swiss bacteriologist, was born at Geneva, Switz., on Aug. 8, 1882. He produced his first tuberculosis serum in 1912, and in 1913-14 treated a number of patients at London hospitals, with good results. During World War I, being unable to continue the production of his serum, he manufactured large quantities of tetanus serum for the Allied armies. In 1916 he began to reproduce his antituberculous serum. which was in almost complete form in 1919. The Spahlinger treatment was based on two different therapeutic principles, according to the disease: passive immunization, or serum treatment, and active immunization, or vaccine treatment. He later studied the endocrine glands and their relation to disease resistance and longevity.

SPAIN, in its own language España, a state in the southwest of Europe, comprising eleven-thirteenths (190,115 sq.mi.) of the Iberian peninsula and in addition the Balearic Islands (1,936 sq.mi.), the Canary Islands (2,894 sq.mi.) and certain towns on the Mediterranean coast of Morocco (Ceuta, Peñón de Vélez, Alhucemas and Melilla), with the Chafarinas Islands.

The Spanish protectorate of Morocco extends over a northern and a southern zone (see Morocco), with capitals at Tetuán and Cabo Juby (Villa Bens) respectively. The colonial possessions of Spain are: Ifni territory (741 sq.mi.; capital, Sidi Ifni); Spanish Sahara (Río de Oro, 73,362 sq.mi., and Saguia el Hamra, 32,047 sq.mi.; capital, Villa Cisneros); and Spanish Guinea (Río Muni and the islands of Fernando Po, Elobey, Annobón and Corisco, in all 10,852 sq.mi.; capital Santa Isabel, on Fernando Po).

This article is concerned with Spain proper; i.e., with the Spain of the Iberian peninsula.

### PHYSIOGRAPHY

The Iberian peninsula covers the major portion of that section

47' N. (Estaca de Vares) and 36° o' N. (Isleta de Tarifa) and between the meridians of 3° 19' E. (Cape de Creus) and 9° 30' W. (Cape da Roca). Of its area of about 223,000 sq.mi., approximately 85% is Spanish. It has been thought proper, therefore, to treat here of the physical geography and geology of the peninsula as a whole rather than to confine the treatment to Spain.

The peninsula is the least European in appearance of the three great Mediterranean peninsulas. Its massif character, the great central Meseta, the narrow Strait of Gibraltar by which it is separated from Africa and the high barrier of the Pyrenees by which it is separated from the rest of Europe all give it the physical appearance of a disconnected outlier of the Moroccan Meseta rather than that of a part of Europe. Moreover, it is separated from the Mediterranean by coastal ranges which leave between themselves and the sea only narrow and discontinuous strips of coastal plain that alone, of all the peninsula, have a Mediterranean history.

At first glance it would seem that the peninsula should serve to unite Africa and Europe; instead, its ranges of east-and-west mountains serve to separate them. Moreover, the peninsula furnishes no natural traffic routes between the Mediterranean and the Atlantic or between the Mediterranean and northwestern Europe. The closer physical connection with Africa than with the rest of Europe had the consequence of the Islamic invasion and the 500-year struggle with Islam which is accountable in large part for the slow development of Spain along European lines. The physical character of the peninsula likewise resulted in the separation of Portugal from Spain and the 700-year separation of the kingdoms of Castile and Aragon. So sharply defined are the natural regions occupied by these two states that even now their peoples differ sharply in physical type, customs and social organization.

The Coasts.-Seven-eighths of the border of the peninsula are washed by the sea; yet the peninsula as a whole has relatively little access to the sea and comparatively few good harbours. The Portuguese seaboard is 500 mi. long and, as compared with the rest of the peninsula, relatively low. On the southern half of the coast, however, mountain masses and spurs terminate in a number of high rocky headlands like Capes Mondego, Carvoeiro, da Roca, Espichel, de Sines and St. Vincent. The lagoon of Aveiro and the estuaries of the Minho, Douro, Mondego, Tagus, Sado and Guadiana rivers deeply indent the coast and furnish the principal harbours. The high continental mass which forms the greater part of Spain has practically no navigable rivers and a coast line that is for the most part steep and rocky, with relatively few indentations that are easily approached from the interior. The northern coast has numerous indentations that form convenient harbours for small craft, although the current that flows eastward along it frequently builds bars at their mouths. The best harbours are found in the rias or fjordlike indentations of the coast of Galicia. There are the fine natural harbours of Pontevedra, Vigo, Corunna and Ferrol. Bilbao, on the Nervión river, has been since mediaeval times the principal maritime outlet of the Basque provinces. Santander and San Sebastián, likewise on the northern coast, are secondary centres of overseas shipping.

Along the Gulf of Cádiz is the broadest coastal plain of the whole peninsula. Eastward as far as the marshes at the mouth of the Guadalquivir (Las Marismas) it is lined by a series of sand dunes and bordered in part by a line of low, wave-built islands. Eastward from the mouth of the Guadalquivir the coast is more varied and includes the excellent harbour of the Bay of Cádiz.

The Mediterranean coast is bold and rocky from the Strait of Gibraltar almost to Cape Palos but is broken by the British-owned harbour of Gibraltar and the fine harbour of Cartagena. North of Cape Palos the coastal ranges again recede, leaving a narrow coastal plain; but in the northern part of the province of Alicante the mountains again advance to the sea and form the lofty headland of Cape de la Nao. The whole coast of the Bay of Valencia is low and swampy and lined with lagoons, furnishing little in the way of good harbours. All this coast is built of sediments brought down from the Meseta. This sedimentary character IO8 SPAIN

culminates in the great delta of the Ebro river. North of the mouth of the Ebro the coast alternates between playas and rocky headlands. The Liobregat river also forms a considerable delta just south of the harbour of Barcelona From Barcelona a long monotonous sand beach extends to the mouth of the Tordera river. There begins the famous Costa Brava, divided into two sections by the Gulf of Rosas and presenting a rough varied coast line of

deep coves and steep, rocky bluffs.

Inland Configuration .- The surface of the peninsula is noted for its contrasts and its vast expanses of dreary uniformity. There are mountains rising with alpine grandeur above the snow line, but often sheltering rich and beautiful valleys at their base. Naked walls of white limestone tower above dark woods of cork and olive. In other parts, as in the Basque country, in Galicia, in the Serranía de Cuenca (between the headwaters of the Tagus and those of the Júcar), in the Sierra de Albarracín (between the headwaters of the Tagus and those of the Guadalquivir), there are extensive tracts of undulating forest-clad hill country. Almost contiguous to these there are broad plains of level tableland, some almost uninhabitable and some with a network of irrigation canals and richly cultivated like the Requena of Valencia. Continuous mountain ranges and broad tablelands give the prevailing character to the scenery; but there are, in addition, lofty isolated mountain peaks such as Monseny, Montserrat and Mont Sant in Catalonia, the Peña Golosa in Valencia and Moncavo on the border of Aragon and Old Castile, as well as many small secluded valleys such as those of Vich and Olot among the Catalan Pyrenees.

The Meseta and Its Borders.—More than half the peninsula is occupied by the Meseta, an ancient earth block consisting mostly of flat-lying strata. broken and eroded and reduced in large part to a state of peneplanation. The Meseta slopes gradually from north to south and from west to east, its average altitude being about 2,000 ft. On the north it is bordered by the Cantabrian mountains and on the northeast by the Iberian ranges, which separate the Meseta from the deep tectonic depression in which flows the Ebro river and terminate near the Gulf of Valencia. On the south the Meseta is bordered by the Sierra Morena, which is actually only the sceep southern edge of the Meseta along the Baetic depression, and the Sierra de Alcaraz between the headwaters of the Guadalquivir and Segura rivers.

The Cantabrian mountains are divided into two sections-the Cantabro-Asturian section on the northern border of the Meseta and the Galician section which extends into Portugal as far as the Douro river. The Cantabro-Asturian section runs sensibly parallel to the north coast and culminates in the Peña de Cerredo (8,786 ft.), the highest point in the ranges of the Meseta. A characteristic of these mountains is the many parameras or isolated plateaus surrounded by steep mountains or walls of sheer cliff. On account of the diversity of their origin and their many interruptions the Iberian ranges can be characterized better as the upturned northeastern corner of the Meseta than as a true mountain system. This corner reaches its highest point in the Sierra de Moncavo (7,595 ft.). South of the Jalon river it divides into two sections: one, which borders on the Meseta, forms the broken and picturesque Serranía de Cuenca: the other, which lies nearer the Ebro depression, forms the coast ranges that border the low, lagoonstrewn Bay of Valencia.

The Meseta is divided by a central cordillera into northern and southern submesetas, representing the ancient regions of Old Castile and New Castile. This central cordillera consists of a series of crust-block mountains formed by successive fractures and vertical movements and extending en échelon northeastward from the Atlantic coast near Lisbon to the Nudo de Albarracin, where it connects with the Iberian ranges. It divides the basin of the Douro river from that of the Tagus. There are lofty peaks reaching above the line of perpetual snow in the sierras of this central cordillera. The highest peak, the Plaza del Moro Almanzor (8,504 ft.) in the Sierra de Gredos, is only a little lower than the highest of the Cantabrian peaks, while the Pico de Pefialara in the Sierra de Gudarrama reaches 7,972 ft. Even these highest crests are, however, only about 5,000 ft. above the general level

of the Meseta. Between the Sierra de Guadarrama and the Sierra de Gredos and between the latter and the Sierra de Gata are high irregular surfaces filled with hills and paramerus.

Parallel to the western part of the central cordillera between the basins of the Tagus and Guadiana rivers are the Montes de Toledo, a shorter series of sierras that form a denuded highland of relatively low elevation and are separated from the Iberian ranges by the section of the Meseta known as La Mancha. Their highest point is Las Villuercas (4,734 ft.) in the Sierra de Guadalupe. Their westward extension into Portugal is known as the Montanhas do Alentejo. The Sierra Morena is an even less continuous range than the central cordillera or the Montes de Toledo. Its westerly extension into Portugal ends at the rocky headland of Cape St. Vincent.

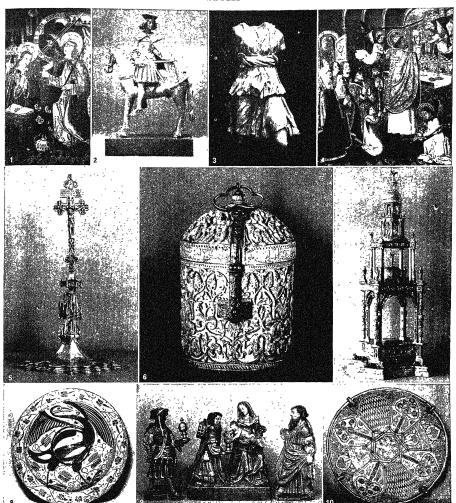

Geologically, geographically and politically the Meseta is the true Spain. On all sides it is in general remarkably isolated from the coast so that the passes on its border and the river valleys that lead from it to the coast and to the Ebro and Guadalquivir depressions have been from earliest time geographical features of the highest importance. On the northwest, communication between León and Galicia is furnished by the Sil river which at an early date was followed by military roads and in modern times became part of the route of the railway to the port of Corunna. In the Cantabrian mountains the passes are fairly numerous and over them lie the routes of several railways connecting the interior with the ports of the Bay of Biscay. The two most remarkable passes in these mountains are the Pass of Pajares, which carries the railway from León to Oviedo and the port of Gijón, and that of Reinosa which leads down to the deep valley of the Besaya and is crossed by the railway from Valladolid to Santander. The eastern part of the range is crossed by railways from Burgos to Bilbao and San Sebastián, the latter following the picturesque gorge of Pancorvo and crossing the range at Idiazabal.

On the northeast the valley of the Jalon affords the most important communication between Madrid and the Ebro,depression. At an early date an important military road followed this depression. It is now traversed by the Madrid-Saragossa railway. Farther south the southerly extension of the Iberian ranges long made direct communication between Madrid and Valencia difficult, and even now, although a branch line connects the Jalon valley with the coastal railway a short distance north of Valencia, the main communications between Madrid and the eastern and southeastern coasts are across the southeastern part of the Meseta and the hill country between the Meseta and the Mediterranean.

The descent from the Meseta to the depression of the Guadalquivir is comparatively gradual; but passes through the eastern part of the Sierra Morena are few, the principal one being the Puerto de Despeñaperros where the Magaña river, a tributary of the Guadalimar, has cut a deep gorge that the railway from Andalusia to Madrid follows in its ascent to the Meseta.

The central cordillera also offers considerable obstruction to easy communication between the northern and southern sumesetas, although the hilly intervals between the sierras afford comparatively easy routes. Carriage roads cross the three main passes in the Sierra de Guadarrama (the passes of Somosierra in the northeast, Novacerrada near the Pico de Peñalara and Guadarrama a few miles south and west), while the railway from Madrid to Segovia passes through a tunnel close to the Guadarrama pass and that from Madrid to Ávila crosses the southwestern portion of the same sierra by a remarkable series of tunnels and cuts. The Sierra de Gredos has a road across it connecting Avila with Talavera de la Reina by way of the Puerto del Pico; but for the most part there are only bridle paths across this sierra and the Sierra de Gata and no railway crosses either.

The Meseta is bordered on the northeast and on the south by two great transverse depressions. That on the south is known as the Baetic depression, now deeply eroded by the bed of the Guadalquivir. It is a gigantic fracture that has cut like a knife across all the strata of the Meseta and stands out with remarkable clearness from Cape St. Vincent to the eastern end of the Sierra Morena. The present Baetic depression is believed to be the remains of a strait which, up to the Tertiary period, connected the Mediter-

ranean with the Atlantic.

Later, on account of movements that produced the Cordillera Penibética by which the present depression is bounded on the south and southeast, this strait was reduced to a gulf opening only to the Atlantic and was in time converted, whether by further uplift or by sedimentation alone, to the present valley. The sedimentary deposits of the Guadalquivir, which flows along the most abrupt border of the depression at the foot of the Meseta, have been built up on the materials worn off from the Meseta during the period of submergence and the sediments of marine origin to form the present fertile valley of Andalusia.

The Ebro depression forms a deep ravine between the northeastern corner of the Meseta and the Pyrenees. Its bordering walls converge to form an angle at the point where the depression is shut off from the Mediterranean by the Catalan coastal range, through which the Ebro river has cut a tortuous gorge. At one time the depression was occupied by the sea, which penetrated by way of the Gulf of Rosas but did not extend to the Bay of Biscay. When the Catalan coastal range emerged the depression was converted into a closed lake. The definition of the Ebro river and the successive terraces which characterize both sides of the depression were brought about by the later uplift from which resulted the present architecture of the Pyrenees.

The Ebro valley is divided into two sections by spurs from the Pyrenees on the one side and from the Sierra del Moncayo of the Ebrian ranges on the other. The uppermost of these, a plateau of between 1,000 and 1,300 ft. above sea level, is only about one-fourth the size of the lower portion. The valley of the Guadalquivir is also divided into an upper and a lower section as indicated by the change in the course of the river from a due west to a more southwest direction. The small upper valley is of considerable elevation while the much larger lower valley is mainly lowland and, from Seville to the sea, is composed of a perfectly level and marshy alluvum (Las Marismas).

Mountains Outside the Meseta Border.—The Pyrenees (q.v.) form a wall between Spain and France with an average altitude higher than that of the Alps. Their snow-capped crests reach their highest point in the Pico de Aneto (11,168 ft.) in the central massif of granitic rocks that forms the range's core. Railroads pierce the Pyrenees over two routes (Jaca-Pau and Ripoll-Foix). The Catalan coastal range that borders the Ebro depression is the youngest range of the pennsula and all evidence indicates that the region suffered movements in the Quaternary period. It represents the upper portions of a land mass now in large part submerged beneath the Mediterranean. The peaks Monseny (5,713 ft.) and Montserrat (4,076 ft.) are the outstanding crests. Erosion has moulded them into picturesque forms. Nearer the coast a series of hills of low elevation borders the Catalan range throughout its whole length.

The Baetic system of the southeastern part of the peninsula has been said to be the result of a series of thrusts that had their focus farther south and forced up against the rigid mass of the Meseta the land mass located in front of it. It is generally accepted that a long longitudinal fault which extends from the lower course of the Segura river to the Genil river divides the system into two groups. The mountains to the south of this fracture are known as the Cordillera Penibética. They lie near the Mediterranean coast and are considered to be prolonged across the Strait of Gibraltar by the mountains of the Rif. The great block of the Sierra Nevada of the Cordillera Penibética contains the highest crests of the peninsula and reaches its greatest altitude in Cerro Mulhacén (11,414 ft.). It is completely alpine in character with glacial cirques, lakes and moraines. The Cordillera Penibética includes at its eastern end the volcanic zone that forms the Cape de Gata. The extension westward from the Sierra Nevada to Point Marroquí appears to be cut by a series of transverse faults. The mountains north of the Penibaetic fault, though not exhibiting the high crests of the Cordillera Penibética, have a much broader area of high altitudes. They close the eastern end of the Baetic depression and extend eastward to form the Cape de la Nao. The dividing line between them and the Iberian ranges is generally placed at the Júcar river.

Rivers and Lakes.-The main water divide of the peninsula follows rather closely, in the north, east and south, the border of the Meseta and the greater part of the drainage is westward by four large rivers, the Tagus (Spanish Tajo, Portuguese Tejo), Douro (Spanish Duero), Guadiana and Guadalquivir. Only a limited part of the northeastern corner of the Meseta is drained by the Ebro on account of the barrier of the Iberian ranges, and all the remaining rivers which drain to the Mediterranean are short as compared with those draining to the Atlantic. All the large rivers of the Atlantic slope rise in Spanish territory. The Tagus and the Douro have their lower reaches in Portugal and the lower Guadiana is partly in Portugal and partly on the boundary. Only the Guadalquivir and the Ebro, of the larger rivers, are entirely in Spanish territory. The longest of the rivers is the Ebro (575 mi.). The rest in order of their length are the Tagus (565 mi.), the Guadiana (510 mi.), the Douro (480 mi.) and the Guadalquivir (350 mi.). The Minho, which divides the Cantabrian from the Galician mountains, and its tributary, the Sil, which rises in the northwestern corner of the Meseta, are much shorter.

The mouths of the Minho, Douro and Tagus form estuaries which provide good harbours for shipping, but all rapidly become unnavigable toward the interior. In fact only the Guadalquivir can really be classed as navigable for any appreciable distance from the sea, ships being able to ascend it as far as Seville. The others flow in deep rocky valleys which they have cut across the Meseta. Their water supply is scanty, their deeply cut valleys are difficult to cross and the river beds so far below the level as to make them useless for irrigation. The Ebro makes its way to the Mediterranean by way of a tortuous gorge and so affords no means of river transportation to the sea. Its great importance lies in its plentiful waters for irrigation purposes derived from both the Pyrenees and the Cantabrian mountains. Lakes of any considerable size are few, the only important ones being two coastal lagoons near the Mediterranean-the Albufera de Valencia, the Mar Menor in Murcia-and the Laguna de Janda in Cádiz behind Cape Trafalgar. There are many small alpine lakes and small salt lakes are to be found in every steppe region.

#### GEOLOGY

Geologically the Iberian peninsula consists of a great massif (the Meseta) which has been composed by Archaean, Palaeozoic and eruptive rocks partly concealed by a covering of Tertiary strata but characterized by the absence, excepting in its margins, of any marine deposits of Mesozoic age and bordered on the north, east and south by zones of folding in which the Mesozoic and early Tertiary beds are involved.

The Meseta is a fragment only of the great Hercynian mountain system which was formed across Europe at the close of the Carboniferous period. The earth block which forms the Meseta was individualized at the close of the Palaeozoic era. During the Mesozoic era the Hercynian system of which it is a part was shattered and large portions of it sank beneath the sea and were covered by Mesozoic and Tertiary strata. But other portions remained above the sea and of these the Meseta was one. Around it the deposits of the Jurassic and Cretaceous seas were laid down. During the Tertiary era these deposits, together with the earlier Tertiary beds, were crushed against the old massif, thus forming the folded zones of the Baetic ranges on the south, the hills of southern Aragon in the east and the Pyrenees on the north.

There are clear evidences of earlier (Huronian and Caledonian) movements on the Meseta, but worn folds of Carboniferous formations embedded in the Hercynian structure may represent in places an older discordant structure resulting from earlier movements.

Tertiary movements soldered to the Meseta the formations of the northeast, where the folding action lay within the early (Palaeogene) Tertiary period, and of the southeast, where the folding was most intense, in the later Neogene period before the Tortonian epoch. The Tertiary pressures also caused many important movements in the Hercynian massif itself; ancient fractures were rejuvenated, large interior basins were formed and the strata were folded and crushed with great violence in the borders of the massif. During the Pliocene period the Meseta was given a general tilt westward. Later differential Tertiary movements modified the central cordillera system and accentuated the separation of the northern from the southern submeseta.

The areas of regional metamorphism on the Meseta are formed of plutonic rocks, broadly granites, which pass upward into an Archaean or strata-crystalline series in Galicia, Portugal and the central cordillera system. They appear elsewhere aligned with the Palaeozoic series, principally along a line from Alcántara to Andújar. This series shows these levels: the lowest, augen-gneiss; the intermediate, micaceous gneiss with schists and crystalline limestones intercalated; and the uppermost, lustrous schists and phylltes These materials appear now at the surface among granitic rocks in the massif of Galicia and northern Portugal and the central sierras, in the Montes de Toledo and in southern Portugal on the plateau of Évora and Beja which extends eastward by the Sierra de Aracena to the Sierra Morena at a point north of Seville.

Palaeozoic.—The oldest Palaeozoic strata are referred, from their included fossils, to the Cambrian, Ordovician and Silurian systems. They range through a vast region of Andalusia, Estremadura, Castile, Salamanca, León and Asturias and along the peaks of the Pyrenees and the Cantabrian mountains. In eastern Galicia and Asturias and in western León the Cambrian and Silurian trend lines swing round a quarter circle following the outline of Galicia and northern Portugal. The Silurian of the sierras (Ocejón, Alto Rey) lying to the northeast of the Sierra de Guadarrama trends south-southwest, south and, finally, southwest. Round the gneissic vestiges of the Toledan massif the Cambrian and Silurian, partly metamorphosed in the neighbourhood of the granites, trend westward and then northwestward in the Montes de Toledo and the Sierra de Altamira. From the Sierra Morena front the trend lines, running at first parallel to the line of front, swing to the west and west-northwest round the strata-crystalline of southern Portugal. Farther east they run freely to the northwest in the great belt of Palaeozoic which stretches from La Mancha to beyond the Portuguese frontier. The older Palaeozoic of the north culminates in the Teleno (7,181 ft.) belonging to the Montañas de León. In the south the Sierra Morena is the scarped southern edge of the main mass of the Palaeozoic, cut by a series of faults partly of Permian and partly of Pliocene date. The Palaeozoic also formed the two plateaus to the south of the Sierra Morena and a low plateau in the east notable for the complex lead-silver zone of Linares and La Carolina; and a broad plateau in the west extending from the Andévalo district south of the Sierra de Cuacena to the western shores of Portugal.

In the hinterland the Palaeozoic sierras trend finally to the northwest, washing the Hercynian axial lines which curve into this direction from both the Sierra de Toledo and the Sierra Morena. At Montoro the course of the Guadalquivir has been imposed on the Palaeozoic by the removal of overlying Tertiany formations. East of Almadén the Palaeozoic is pierced by Quaternary basalts of the Campo de Calatrava beyond which tongues of Mesozoic projecting from La Mancha bring the Guadiana drainage into the Palaeozoic area,

Mesozoic.—In Portugal the Mesozoic series consists of deposits laid down in the geosyncline which existed to the west of the latesta during that era and which disappeared at its close after retreating north of the present Tagus river draining the Upper Cretaceous. Geosynclinal conditions were most marked during the Jurassic whose "Tusitanian" stage has a thickness of 5,000 ft. in the Törres Vedras area. Jurassic limestones sketch the structural skeleton of the Mesozoic fringe of the Meseta. In the Mondego region a Jurassic upfold, flanked on two sides by Turmian formations, runs west-southwest to Soure and then west-northwest to Cape Mondego by Verride and Buarcos.

This axis delimits on the south an area of worn Cretaceous reliefs above which stands out the Jurassic of Cantanhede, separated from the sea by a broad belt of high dunes. The Cretaceous, which appears in depressions along the principal axis as well as on the flanks of the Jurassic zone, is widely developed in the Cintra region where the Jurassic scarcely emerges. South of the Tagus

river movements of Alpine date have brought up the Jurassic to form the higher parts of the complicated Serra da Arrábida which runs west-southwest to Cape Espichel. In Algarve the Lias and Jurassic, with a fringe of Cretaceous toward the littoral, are folded against the southern edge of the plateau and contribute granite and limestones to the complexity of the zone.

The Lower Carboniferous rocks of Spain consist partly of limestones and partly of sandstones and conglomerates like the culm of Devonshire. It is in the culm of the province of Huelva that the celebrated copper mines of Rio Tinto are worked. The Upper Carboniferous is formed, to a large extent, of sandstones and shales, with seams of coal; but beds of massive limestones are often intercalated, and some of these contain Fusulina and other fossils like those of the Russian Fusulina limestone. In the Cambrian and Silurian areas of the northwest, Tertiary movements have probably compressed the strata in the arc of the western Asturnas, but not in the Carboniferous area to the east where the Carboniferous has its most extensive development in Spain, covering a considerable section of the eastern Asturias and stretching more or less continuously through the provinces of León, Valencia and Santander.

The blue-gray mountain limestone of the Lower Carboniferous forms the triple massif of the Picos de Europa and the crests of many sierras. The culm, which also forms mountains, especially along the upper Deva, marks the transition to the continental conditions in which originated the sandstones and slates of the middle Carboniferous, with their intercalated beds of coal, principally the beds of the Tangres and Mieres basins. Tertiary movements raised the Carboniferous along an east-west axis to form the Cantabrian chain.

To the north of the Carboniferous of the central Asturias lies an area of Mesozoic marine invasion with deposits in a belt trending east and west behind the Palaeozoic "island" by the Cape de Peñas district. From Peña Prieta eastward the altitude of the summits of the Cantabrian chain declines and the Gretaceous is rapidly substituted for the Carboniferous. In the half circle between Peña Tabra and the Sierra de Alcaraz the Meseta is bordered by highlands principally of Mesozoic formations. The tectonic relations between these highlands and the Cantabrian system, which continues eastward in the Cretaceous to the Pyrenean front, are not clear.

The Permian is probably represented by some of the red sand-stones, conglomerates and slates in the Pyrenees, in the Sernain de Cuenca and in Andalusia. The Triassic system is well developed in the north of the peninsula along the Cantabrian chain and eastward to the Mediterranean. It is composed of red and variegated sandstones, dolomites and marl, and contains deposits of gypsum, aragonite and rock salt. The Jurassic overlies these strata and is especially important in the eastern part of the peninsula between Castile and Aragon, along the Mediterranean border, in Andalusia and on the flanks of the Pyrenees. The early Jurassic conglomerates and grits are followed by limestones, some dolomitic variegated marl and overlying spongy limestones or dolomites. The neritic Lias and Jurassic are important only on borders of New Castile.

The Cretaceous forms the broad plateau of La Lora on the southern front of the Cantabrian mountains northwest of Burgos and extends southward and westyward into a Cretaceous isthmus in the northern side of the Miocene "Straits of Burgos." An upfold brings it to the surface again in the islandlike Sierra de Atapuerca on the south side of the "straits" toward the Montes de Oca. From the scarp of the Urbión the Cretaceous dips gently southward and Upper Cretaceous limestones form small, bare, fault-bounded plateaus sharply contrasting with the pine-clad slopes of the Lower Cretaceous and appearing at the surface not only on the margin of the zone but in the upfolds of small radius among the Tertiaries of the Douro, at El Burgo de Osma. Soria and elsewhere.

South of the Jalón river beyond the Parameras de Molina the border of the Meseta is formed principally of Jurassic limestones and marl commonly capped by horizontal limestones of the Cretaceous and forming a series of high plains rather than mountains in which the *muela* or molar-tooth summit is typical. The dif-

ferent alineations, however, are known as the Serranía de Cuenca, the Montes Universales and the Sierra de Albarracín.

Tertiary.—Deposits of Tertiary age cover rather more than a third of Spain. On the Meseta the Tertiary formations were laid down in the basins of Old and New Castile and in the minor systems of Castelo Branco (Beira Baixa), Badajoz and others of the Tagus and Guadiana valleys. In the west arkose grits of Lutetian date form a broad, monotonous plain in the provinces of Zamora and Salamanca, and the old Tertiary (Palaeogene) beds appear also in the east near Lerma and in the plateau of Soria. Elsewhere the outer deposits of Palaeogene are insignificant. The continental Miocene, unconformable on the Palaeogene, consists of fine-grained materials laid down within the basins of the Palaeogene; and the Cretaceous to which it is unconformable had been folded in the margins of the basins, by rivers (Tortonian), brackish ponds (Sarmatian) and the marshy ponds (Pontian). In spite of stratigraphic discontinuity the forms of the Miocene relief are constant and characteristic.

The type form is the tableland (mesa), with its flat upper surface of the limestone cap (páramo), its slope of marl (cuesta) and its sands or clays of the lower slopes forming plains (lamass, campiñas, campos). As the erosion advances the worn tablelands appear as truncated pyramids or form low mesas capped by the beds of harder marl. Finally great stretches of plain are formed on the level of the Tortonian on lower Sarmatian. Elsewhere, the Eocene marine strata are developed in the basin of the Ebro, and Miocene deposits occupy some small tracts especially on the coast of Valencia, although most of the sandy Tertiary rocks of the latter district are Pliocene. In the Baetic depression the marls of the Tertiary rocks of whatever level are of great importance, supplying the rich soil of the Cijarafe olive groves west of Seville and of the vineyards of Jerez.

Other Features.—Quaternary deposits spread over about a tenth of the country. The largest tract of them is to be seen to the south of the Cantabrian mountains. Another flanks the Sierra de Guadarrama and spreads out over the great plain from Madrid to Cacers.

From the rivers Douro, Tagus, Guadalquivir and Ebro, E. Hernández-Pacheco described four fundamental terraces at heights of 30, 100, 200 and 330 ft., which are fairly constant within limits of 4-33 ft. from the higher terraces, and he commented on the absence of terraces on the Spanish section of the Guadiana river. The highest terrace is of late Pliocene date, and to it are referred the famous rañas, extensive platforms of coarse detritus high on the northern front of the Montes de Toledo. The others seem to be related to the terminal moraines of the Pleistocene glaciation with which, in some cases at least, they are continuous. These moraines are found as low as 2,300 ft. on the Serra da Estrêla (one of the westernmost sierras of the central cordillera); and the topography of the Picos de Europa (of the Cantabrian mountains), the Sierra de Guadarrama and the Sierra de Gredos (of the central cordilleras), the Sierra Nevada and the Iberian ranges from the Demanda to Moncayo has been modified to some degree by glaciation. But the centres of glaciation in each of these cases were relatively small, and the action local. Only in the Pyrenees are the glacial phenomena of real topographical importance. The terraces, however, are of first importance, making irrigation possible in areas otherwise arid.

# CLIMATE AND SOILS

Looking at Spain, as a whole, for the year as a whole, we can distinguish, in respect of temperature, the very different climates of the equable Biscayan and northern Atlantic coasts; of the interior, with extremes of temperature always, but with a winter that varies from the traditional nine months of the higher parts of Old Castile to the short two months' winter of the lowlands of Estremadura; of the Mediterranean coast with its very short winter and rather hot summer; and of the subtropical south and southeast, where winter, in the popular sense, hardly exists.

More important is the distinction in respect of rainfall between Spain of the northwest and north (roughly as far south as the line León-Pamplona-Huesca), with a mean annual rainfall of 24 in.

and more, fairly well distributed over the year; and the rest of the country, arid Spain, with rains insufficient in quantity or badly distributed or, more commonly, both. There is a general decline in the mean annual rainfall from northwest (Santiago, 66 fh.) to southeast (Almería, c. 10 in.), but this is interrupted by the mınımal rainfall of the basin of Old Castule, where. Salamanca and Zamora, like Saragossa in the Ebro basin, lie within an Isohyet of 12 in, and by the orographic rainfalls, which are sometimes remarkable. Thus, in the Baetic calcareous zone, in spite of a rainless summer season, the annual rainfall may be 80 in, on the outskirts of the Serranía de Ronda.

The rains of arid Spain are spasmodic, Mediterranean rains falling in large drops for a few hours of a few days of the year. They are also irregular in amount from year to year, the rainfall records of 95 years for San Fernando, near Cádiz, for example, show a mean deviation, from the mean, of 26%. (Annual records from 48 stations are practically complete from 1920 on, and a few are much older.)

Irregularity of the seasonal rain supply and the entrenched courses of the rivers of the interior prevent much use being made of their waters for irrigation. To overcome both of these difficulties for the rivers of the Ebro system immense engineering works were planned. (See Aracon.) On the lower courses of the rivers of the short eastern slope the relief is, by exception, highly favourable to the establishment of important irrigation systems. (See VALENCIA)

Properly conserved, arid soils, although they are inevitably exposed to the sterility resulting from sequences of years of drought, have, nevertheless, certain advantages of chemical composition because of the smaller degree to which plant foods are lost by leaching, which enable them to maintain a standard of productivity lower than that of more humid regions and requiring a greater output of labour, but more independent of artificial fertilization, especially if natural manure is supplied by pasturing. Dry farming, the cultivo de secano, is the third and most widespread of the geographical institutions of arid Spain.

Subsoils include the Andalusian black earths and new soils, chestnut or red in colour. An extreme type is the calvero soils. In the calveros, which arise commonly from attempts to extend cultivation beyond its proper limits, the soil cap is discontinuous and the native rock conspicuous on the surface; tufts of permanent vegetation depend on and protect the small patches of soil; in the open spaces lichens are the chief covering, with occasionally transitory grasses.

Saline soils occur locally, in the more arid, parts of Old and, especially, of New Castile and of the Ebro basin and elsewhere; but the extension of the saline area is greatly modified by human agency. In eastern Spain, in general, and in Andalusia, red soils, the Mediterranean red earths, are commoner than chestnut, and in the dry southeastern corner tawny or gray soils are commoner than red; the precise significance of the colour is not known.

## FLORA AND FAUNA

Flora.—Because of the extraordinary variety of climates, altitudes, exposures and soils, there are more botanic species in Spain than in any other European district of the same size. The number of endemic species, particularly on the tablelands and the mountain ranges, is exceptional. Spain may be divided botanically into four zones.

In the humid north and northwest the flora is mesophytic, of the same type as that found in central and western Europe. A great part of the country once covered with forest is now barren. Deciduous trees flourish only in the north and northwest or on damp mountain slopes and along watercourses. Typical of these are oaks, beech, birch, ash and sweet chestmut. In the Pyrenees they ascend to about 5,000 ft., above which level grow birches and conifers such as silver fir (Abies alba), mountain pine (Pinus anugo) and Scotch pine (Pinus sylvestris). Higher up are alpine meadows and heaths, rich in alpine flora. Westward from the Pyrenees, through the Basque country and the Cantabrian mountains to Galicia, the lower slopes are well wooded. Higher up, heath moors contain box, blackberry, gorse and heather; while

apples are cultivated in the open meadows and maize, oranges, lemons and other fruits near the coast.

The central tableland or Meseta and the steppe lands carry xerophytic types. Typical trees are pines and evergreen oaks (Quercus ilex and Q. suber), though poplar and ash grow by the streams. On the deforested areas above 7,000 ft. thin matorral, mainly broom heath, is found. Matorral consists of a scrub of evergreen bushes and herbaceous plants belonging mainly to the Cistaceae, Labiatae, Leguminosae and Ericaceae families. flourishes where there is plenty of sunshine, low rainfall and high evaporation. Myrtle (Myrtus communis), mastic bush (Pistacia lentiscus), sage (Salvia officinalis), sweet marjoram (Origanum majorana), wormwood (Artemisia absinthium) and tree heath (Erica arborea) are common in mattoral. As the soil becomes more arid this changes into steppe which consists chiefly of bare ground sparsely covered with small bushes and tufts of grasses. Spanish broom (Spartium junceum) and gorse are common northeast of the Sierra de Gredos, on the southern side of which olives, figs and vines are cultivated, while on the rocky western slopes are huge areas of woody labiates.

On the Montes de Toledo and Sierra Morena are matorrales of broom heath and cistus. Those dominated by cistus are known as jarales. On the vast plains of La Mancha the matorral is of aromatic labiates such as thyme, lavender and rosemary (these are known as tomillares). Sometimes the scrub is very dense and may be 10-15 ft. high, though typically it is about 6 ft. high. In the Sierra Morena evergreen oaks are the dominant trees with ash, alder, black poplar and others along the river banks. There is a great deal of cork oak (Quercus suber) in the southwest and sweet chestnut (Castanea sativa) in the west. Steppe lands occur mainly in the high southeastern plains where the climate is dry and the soil sandy or salt. There is a large variety of plants, but esparto

grass (Stipa tenacissima) is dominant.

In the dry Andalusian plain of the southeast, African and semidesert plants are found. Much land is under cereals and legumes, though there are many vineyards and groves of oranges and olives. Along the streams grow patches of dwarf palms (Chamaerops humilis), prickly pears and oleanders. In the Andalusian mountains evergreen oaks grow everywhere, pinewoods in the hollows, and olives are common. The matorral is chiefly of cistus and labiates. On the Sierra Nevada typical Mediterranean fruits grow about 5,000 ft. up, below the matorral of gorse and aromatic shrubs. In irrigated parts cultivated fruit trees form gardens called vegas or huertas. The flat marshy expanse of Las Marismas, near the mouth of the Guadalquivir, supports reeds and salt-marsh plants.

The lush, green, almost tropical vegetation of the southern coastal strip is the result of irrigation. Date palms, bananas, sugar, rice and cotton are grown in vegas. On the hills grow pines, oaks and carob, along the coastal areas jujube, almonds, figs. olives and pomegranates and on the lowlands mastic bush and sweet

laurel.

On Spain's Mediterranean coast line Catalonia has the densest vegetation. South of Barcelona are woods of pine and cork oak as well as typical matorral. Oleanders grow in the Ebro valley. North of Barcelona cork flourishes. The rainfall is higher there and so eucalyptus, pines, cypresses and poplars are common. Farther north the deciduous trees are found and the Mediterranean

flora merges with the Pyrenean.

Fauna. Cut off from Europe by the Pyrenees and formerly joined to Africa, Spain has two clearly distinguished groups of animals. The first group includes both species found in the temperate forests of central Europe and occurring in the north of Spain and also isolated colonies of alpine forms occurring in the higher mountain ranges—for instance, deer, ibex, eagle, vulture. The second group is typically Mediterranean and is found in Spain in the dry southeastern regions; there are many indigenous forms and many North African species.

Almost everywhere are found the rabbit, various dormice and squirrels, the rat (Rattus norvegicus) which was probably brought into Spain by Napoleon's armies in the 19th century, bats (21 kinds, including the only tropical species found in Europe) and red

deer. Indigenous to the country are the Spanish hare (Lepus granatensis), the water vole (Arvicola terrestris sapidus), the squirrel (Sciurus vulgaris segurae) found in the Sierra de Segura, the red deer (Cervus elaphus hispanicus) and the Spanish ibex (Capra pyrenaica).

In the region of the Pyrenees the fauna is similar to that of France. There live the squirrel, mole, chamois, hare (Lepus europaeus) and bear (Ursus arctos). In the Cantabrian mountains the fauna is of the European type and includes the chamois, gray dormouse, squirrel, bear, yellow marten and ermine. The typical animals of Galicia are the Galician hare and the ibex.

In the central placeau of Spain indigenous species of squirrel, mole, muskrat and roebuck are found. In the Sierra de Guadarrama live species of wolf, lynx, genet (an African animal), stone marten, badger, weasel and fox. In the central strip between the Tagus and Guadiana rivers there is a predominance of African species. Among the indigenous animals of the southeastern regions are peculiar species of jackal, wolf, squirrel and rabbit. In the lower Guadalquivir valley lives the wild boar.

In Andalusia are a species of dormouse, the Egyptian mongoose (Herpestes ichneumon widdringtoni), which is not found in Europe except in the Iberian peninsula, the Andalusian weasel and the hedgehog, while the ibex inhabits the mountains inland from the Mediterranean. At Gibraltar are the famous Barbary apes, probably introduced from Africa. There are no squirrels in the Mediterranean regions.

As Spain is on the route of bird migration between northern Europe and Africa, many species, such as ducks, wild geese and wading birds, winter there on their way south. Others such as flamingos, snipe (by the Guadalquivir), two sorts of quail and the southern shearwater (in the south) stop in the spring, on their way north from Africa.

Birds of prey are numerous and varied, the most common being the buzzard. There are many kinds of vultures, hawks and eagles. The imperial eagle (Aquila heliaca adalberti), also found in North Africa, is indigenous and so are some owls, the royal cuckoo (Cuculus canorus minor) and, in central Spain and the Sierra Morena, the azure-winged magpie (Cyanopolius cooki), otherwise only found in northeastern Asia. Common on the steppes is the red-legged partridge, and the great bustard feeds in flocks in the cornfields of the Meseta.

Amphibians and reptiles are particularly numerous in the south. There are many lizards, chameleons in the Guadalquivir valley, salamanders in the mountains, tortoises and, everywhere, frogs and toads. Trout abound in the mountain streams and lakes, and barbel, carp and tench are common fresh-water fish.

The insect life is quite varied and contains African and European species. Those in the rainy northwest are different from those in the arid zones, where the praying mantis and locusts are

It is impossible to introduce any accurate chronology into the prehistory of Spain. Before the Roman pacification in the 2nd century B.C. with its certain dates and events lie a couple of centuries of Punic penetration from Carthage; still earlier we know

SPAIN II3

of the coasting voyages of Greek traders along the Mediterranean shore and catch some glimpse of the Iberian civilization with which these Greeks came into contact; but all this brings us only into the 7th century B.C. Perhaps for several hundred years before the advent of the Greek ships there had been Phoenicians, mainly from Tyre and Sidon, who had maintained trading posts along the southern shore of Spain and had sailed through the Gibraltar straits to Cádiz on the Atlantic. Then the perspective of years lengthens out immeasurably and we step back, not by centuries but by thousands of years, through neolithic into palaeolithic times, when some type of men—we cannot guess to what race they belonged or what form of language they knew—hunted the beasts of those early days and decorated with marvellously fine likenesses of these animals the inner walls and roofs of deep caverns.

Palaeolithic Spain.—These cave paintings rank among the most impressive discoveries of the past. There can be no doubt of their vast antiquity, since they certainly represent animals of the late Quaternary geological period and are engraved upon bones which are identifiable as those of animals now long extinct. Nor can there be much dispute about the extraordinary veracity and vivacity with which wild horse and bison, hind and stag, ibex and ox and boar are delineated with little save their outline and with no visible hesitation of stroke.

The best-known of the Spanish caverns and one of the first to be discovered is Altamira near Santander. The publication of its contents by Edouard Cartailhac and the abbé Henri Breuil (Monaco, 1906) is the best introduction to the study of palaeolithic Spanish archaeology. Other important sites are Hornos de la Peña, Pasiega and Castillo in the province of Santander; Basondo in the province of Biscay; and Pindal, Buxu and La Peña in Asturias. Palaeolithic decorated caverns are largely confined to the small mountainous area in the north which extends from the westernmost Pyrenees through the coastal hills beyond Santander. They may therefore be justly termed Cantabrian. Elsewhere, however, beyond the Spanish border, the same type recurs, chiefly on the northern slopes of the Pyrenees and in the region of the Dordogne in southwestern France. These three districts—the one in northern Spain, the two others in southern France-are inseparably allied and were products of contemporary cultures. In other parts of Spain, where caves are little more than open rock shelters, a distinctively different art has been found.

Prehistorians therefore speak of "cave art" and "rock-shelter art," and distinguish sharply between Cantabrian and east Spanish palaeolithic. Beginning in the early 1920s there was great activity in the exploration and elucidation of this second group. Except that the fauna of the paintings there implies a slightly warmer climate, much the same series of animals are rendered in much the same style; but intimately combined with them appear weirdly represented men and women-a subject almost completely neglected by the Cantabrian cave artists. Often the men are armed with bow and arrow and shown in pursuit of their quarry; but whereas the beasts are naturalistically correct in the surprising palaeolithic manner, some of the huntsmen with threadlike limbs more nearly resemble the praying mantis, while others with sudden protuberances of calf or thigh suggest unevenly inflated rubber toys. The women, in long flounced petticoats very remotely suggestive of the elegant ladies of Minoan Crete, seem to take part in dances and conversations, poorly visualized and crudely rendered. This striking combination of a naturalistic animal art with geometrically conventionalized, highly primitive human representations is a phenomenon of great significance, since the groupings and actions of the men and women are almost as clearly allied to palaeolithic rock drawings in North Africa as the ibexes and stags, horses and oxen and bulls are allied to the cave paintings of Cantabria. As in historic, so in prehistoric times, the destiny of Spain must have been a succession of invasions, now from the north, pouring round or over the Pyrenees, now from the south out of Morocco and Algeria. The most important sites of the east Spanish group are Cogul by Lérida, Valltorta in Castellón. Albarracin by Teruel, Alpera and Minateda in Albacete and Cantos de la Visera in Murcia-all characteristically within two or three days' journey afoot from the sea.

Neolithic and Bronze-Age Spain.—The Neolithic Age in Spain testifies to a wholly different condition of mankind. Perhaps it is too ingenuously simple to ascribe the naturalism of palaeolithic art to a race of hunters and the geometric conventionalism of the neolithic to a race that tilled the soil. A fairly uniform culture spread over the entire peninsula; for the rock shelters with neolithic drawings have a very wide distribution and show a striking similarity. They have almost no pictorial attraction and often resemble picture script rather than actual illustration. The pottery finds are the great archaeological aid to neolithic chronogy; and the occurrence of some of the conventionalized devices of the rock paintings upon pottery which can with certainty be assigned to the transition from the Neolithic to the early Bronze Age puts the general epoch of this culture beyond doubt.

A closer comparison of ceramic types shows that beneath this superficial uniformity there lies sufficient diversity to warrant many subdivisions. Chief among these is the clear distinction between the more indigenous central and the southeastern or Almería culture which was probably under African influence and may actually have been the nucleus from which the true Iberian culture developed. In late neolithic times the more extensive central culture exhibits a distinctive and striking bell-shaped (the so-called campaniform) pottery. At this time it is likely that there was some exportation of copper and silver from Spain to the nearest of the Mediterranean islands, since there are ceramic affinities with finds of the Aeneolithic Age (or Stone and Copper Age, lasting in Spain from about 3000 to 2500 B.C.) in the Balearics and in Sardinia and Sicily. The peculiar megalithic structures in these parts, such as the talayots of the Balearics, the nuraghi of Sardinia, the underground chambers of Malta, are fairly well paralleled by megalithic grave structures in Portugal and Spain. But there is as yet no certain proof of intercourse between the eastern and western basins of the Mediterranean for these early times.

Somewhat after 2500 B.C. the Bronze Age displaced the Åëneoithic without apparent interruption; but still the Aegean influence, which can be proved to have reached Sicily and southern Italy, failed to extend as far as Spain. If anything, the Bronze Age marks a retrogression in the civilization of Spain, where at midcentury there had been no archaeological discovery to indicate a powerful or wealthy Bronze Age culture even remotely comparable to that of Crete or the eastern Mediterranean lands.

Tartessus.—Herodotus (iv, 152) narrates the adventurous voyage of a Greek sailing ship from Samos, which was driven by storm past the Pillars of Hercules and "at last reached Tartessus. This trading-town was in those days a virgin port unfrequented by merchants, and the Samians in consequence made a greater profit than any Greeks before their day." This event supposedly took place about 630 B.C. During the century thereafter, Tartessus was certainly frequented by trading vessels of the Ionian Greeks of Phocaea in the Bay of Smyrna. It has been maintained that this rich Spanish city on the Atlantic was the Tarshish of the Old Testament, which "with silver, iron, tin and lead" traded in the fairs of Tyre (Ezekiel xxvii, 12).

Yet the modern search for Tarshish-Tarsis-Tartessus failed. The German archaeologist Adolf Schulten after several campaigns regretfully admitted in 1926 that the mysterious city must lie deep underriver and below the ground-water level.

## THE IBERIANS

The whole of the Hispano-Lusitanian peninsula was sometimes called Iberia by ancient writers; but the true focus of the Iberian civilization was the southeastern corner of the land. There, a stock out of northern Africa (Oran?) and therefore probably Hamitic (Berber?) may have been infiltrating ever since the aëneolithic days of the Almería culture (c. 3000 B.C.). They were probably racially akin to the Tartessians, who would therefore have also been African invaders. We become completely certain of their presence toward the end of the Bronze Age and, several centuries later, can trace the diffusion and inland penetration of their culture until it was finally absorbed by the Roman civilization almost as late as the time of Christ. Roman writers describe the typical Iberians as dark complexioned, with unkernot hair, small

of face but with the cheekbones emphasized and the lower lip prominent, small framed, alert and wiry. Iberian bronzes display them as nders of horses, and we know what their swords and daggers, spears and other weapons were like. The women are represented sometimes as wearing a single-piece cloak drawn up over the head from the shoulders like a mantilla or shawl, and sometimes with a short, hooded garment which flares out below the waist and often has swallow-tailed sleeves. We may judge of their jewellery and their headdresses from the famous sculptured bust, the "Lady of Elche." Iberian art was rude but vigorous, with a leaning toward sculptured animals of stone and human figurines in bronze. The pottery was decorated with simple linear themes, artistically of no particular distinction, until Greek examples offered more sophisticated decorative motives to copy. The best Iberian art comes from the provinces of Murcia and Albacete in the southeast, where the Greek influence was strongest. The Iberians lived in walled towns. The cyclopean masonry in the bottom courses of the great walls of Tarragona is indubitably a remnant of an old Iberian stronghold. Tartessus and Massia (now Cartagena) were similarly enclosed; but the Carthaginians completely destroyed both of these cities, making Gades (now Cádiz) take the commercial place of the former and refounding the latter as Carthago Nova. Behind this seaboard fringe of Tartesso-Iberians the high-lying interior was in the possession of a variety of indigenous peoples of whom we have no clear knowledge except that, along with Catalonia, they passed through an early Iron Age (or Hallstatt phase) associated with the invasion of Celtic tribes who, in the 7th and 6th centuries B.C., poured through the Pyrenees by the western passes and gained possession of large areas of the peninsula, submerging the previous inhabitants. The chief Celtic zones today are Galicia and Portugal. This Celtic invasion may justly be called a historical event. We can date its successive waves within a few decades, define its sources, follow its spread and perceive its results. In the extreme northern mountain lands the earlier inhabitants managed to preserve their individuality in the face of the irruption. It has even been argued that the Basques, who maintain customs and a language whose isolation is a mark of extreme antiquity, are ultimate descendants of the palaeolithic Cantabrian folk which produced the cave art so many thousand years earlier. Elsewhere, during the pre-Roman times, we find Celtic tribes (Beribraces, Sefes, Cempsos) in possession of the land.

Such is the ethnic picture during the 6th and 5th centuries B.C. With such a Spain the Ionic Greeks now came into contact, in rivalry with the Carthaginians who had fallen heirs to the centuries-old Phoenician exploitation of these western marts. Neither the Phoenicians nor the Carthaginians left any very permanent mark upon the land, while the Greeks influenced it profoundly. Ships from Tyre and Sidon may have traded beyond the straits and in Cádiz at least as early as the 9th century B.C.; yet modern archaeology, which has located and excavated Greek, Iberian and Roman towns, has not laid bare a single Phoenician settlement or found more important Phoenician remains than the odds and ends of trinkets and jewels and similar articles of barter. The inference is clear that, except perhaps at Cádiz, the Phoenicians built no towns, but had mere trading posts and points of call.

The Phocaean Greeks, on the other hand, whose western focus was Massilia (Marseilles; founded 600 s.c.), founded true colonies along the east and south coasts where unmistakable traces of their settlements have survived. The sites of Hemeroskopeion (near the modern Denia) and Mainake (at the mouth of the Río de Vélez near Málaga) have been identified, though not yet excavated; and Emporion (now Ampurias, on the Pyrenean east coast near the French frontier) has been systematically dug, revealing a fortified town with strong gates and walls, streets more or less at right angles, remains of houses and a shrine of Aesculapius with a cult statue of the god.

While there is almost nothing in Iberian art ascribable to Phoenician or Punic influence, the art of the Greeks had indisputably a revolutionary effect. A collection of sculptures found at Cerro de los Santos in the province of Murcia is a hybrid of archaic Greek and Iberian art. Fragments of ibericized Ionic Greek architectural mouldings were discovered in the same region; and the pottery from Elche and the surrounding districts is full of unmistakable borrowings from the ornamental repertory of Greek vases. The earliest Iberian money was coined in direct imitation of Greek types of the 4th century BC. Archaic Greek bronzes discovered in many parts of Murcia and Alicante and the actual material traces of the Phocaean colonies tell us that the Greeks were once in this part of Spain.

Elsewhere in the Mediterranean this period is covered by written chronicles of the ancient historians; but the records for Spain are extraordinarily meagre. We hear no more about Tartessus after the 6th century B.C. Instead, Greek sources of the 5th century begin to speak of the whole Tartesso-Iberian region as Iberia; and recent archaeological exploration has confirmed this emphasis upon the Iberians and established them as the great civilizing force of that time in ancient Spain.

During the 4th century B c. the Carthaginian encroachment reached most of the Iberian homeland, the Greek contact was broken and the Graeco-Iberian culture in Murcia waned. But in recompense, and probably under the pressure of this Punic expansion, the Iberian penetration of the interior gathered great headway. During the 3rd century B.c. the most flourishing Iberian centre in Spain was the valley of the Ebro, where in the 5th century there had been no Iberian settlements whatever; and Greek writers of the time no longer refer to the Castilian uplands as Celtic but as Celtiberian. Excavation confirmed this gradual iberianization of almost the whole of pre-Roman Spain. Largely as a result of the careful and systematic work of Schulten in laying bare the sites of the Roman and Celtiberian encampments there, an extensive insight into this iberianized Celtic culture of the 3rd and and centuries B.C., in particular that of Numantia, has been gained.

Thus, when the Romans began their efforts to latinize the land after the close of the Second Punic War (201 B.C.), they found not a Celtic civilization like that of Gaul but an Iberian culture of the general type which the Greeks had encountered and influenced before them. Archaeological evidence shows that the Iberian and the Roman civilizations must have co-existed side by side for more than a century. The latest sculptures from Cerro de los Santos, though still Iberian in style, borrow Roman statuary motives. In other regions true Iberian pottery is often found mixed with thoroughly Roman ware (terra sigillata). Iberian jewellery and gold have been found amid Roman surroundings; and most of the coinage bearing in Iberian script the names of Iberian towns dates from after the Roman conquest.

(R. C.; X.)

## THE ROMANS

Carthage, defeated by Rome in the First Punic War, turned to Spain as a natural treasure house to furnish reparations, to finance new offensives and to supply auxiliary troops. Hamilcar's activities after 237 B.C., followed by those of Hasdrubal (including the founding of the fortress at Carthago Nova) and Hannibal, forced upon Rome a difficult, distant and costly war for which it had no desire and which ushered in many decades of stubborn effort to subdue a rich, proud and brave country. Victory in the Second Punic War left Rome with two embryonic Spanish provinces: Hispania Citerior, the eastern coastal strip based on Tarraco (Tarragona) and Carthago Nova; and Hispania Ulterior, comprising the southern coast and the valley of the Baetis (Guadalquivir). Thereafter the task of deepening the provinces by advance inland was bitterly pursued. Year by year, with each province under its proconsul, Roman soldiers and Roman money were poured in, until Scipio Africanus' epic capture of Numantia in 133 B.C. allowed advance northward to the Durius (Douro) and westward to the middle Tagus. Administration, though usually opportunist, was not always merely oppressive or self-interested; and although annual tribute was imposed on native communities they received certain advantages-security, peace, safe communications, new opportunities of production and commerce, employment under Roman arms and acquaintance with Roman civil law. Agriculture, viticulture and fisheries flourished in the south and east, as the local coin types attest, even if these activities were controlled by

SPAIN II5

Pyrenees to Carthago Nova) and coinage developed from the proceeds of the innumerable mines, of which Rome claimed the gold while leasing out the silver, lead and (probably) copper.

When in 80-70 B.C. the Roman Quintus Sertorius used Spanish supporters against Roman political rivals, he did so as the leader of an already half-romanized army. Julius Caesar's governorship of Hispania Ulterior (61-60 B.C.) saw the frontiers extended up to the mouth of the Durius. Later, as dictator, he initiated a new colonial and municipal policy, bringing Italian settlers to Spain and granting Latin rights to certain indigenous communities. Gades became a fully fledged Roman municipium. Roman peace was swiftly followed by Roman political consciousness: language. religion and public life were henceforth moulded and unified by the central Roman model.

Augustus' first task was to undertake, by bloody and savage warfare, the conquest of the northwestern (Asturio-Cantabrian) corner of Spain-not complete until 19 BC. Now, with the whole peninsula tamed, he effected its total reorganization, though the precise date (in any case earlier than 2 B.C.) is uncertain. Baetica (roughly the Guadalquivir valley with the southern coast) became a "public" province, without regular troops, under senatorial proconsular administration; Lusitania (a new province roughly coextensive with modern Portugal south of the Durius) and Tarraconensis (comprising all the rest of the peninsula) were imperially administered under propraetors with three legions as a permanent garrison in the latter. Major regional towns or cities became centres of government and local jurisdiction. Emerita Augusta (Mérida), a pattern of Augustus' many newly founded watchdog colonies of veteran soldiers, typifies, by the wealth of its remains today, their imposing character. Colonies and full municipia, formed ex hypothesi of Roman citizens, were selfgoverning and subject only to citizens' taxes. Unprivileged communities were administered by the provincial governor and subject still to payment of tribute. Although Augustus was chary in extending the Roman franchise, his work for Spain was enormously beneficial and widely recognized as such. The building of roads and bridges, the encouragement of local enterprise, the unification of sentiment and the establishment of profound peace, while raising the standard of living everywhere, were not imposed at the cost of rigid conformity. Political, religious and financial anomalies were tolerated. Rome's principal reward consisted of the vast output (perhaps unequalled elsewhere) of gold, silver, copper, iron, tin and lead from Spanish mines.

The Augustan model was faithfully preserved. Claudius reduced the garrison to two legions, Vespasian to one. The road complex was developed swiftly. Spanish wine, by its cheapness, and oil, by its quality, disturbed the previous pattern of world markets. Vespasian imposed stricter regulations for the control of all the principal Spanish mines, the revenue of which afterward flowed into the imperial treasury. But early in his reign he recognized a century of astonishing progress by simultaneously promoting about 350 unprivileged communities to Latin rights. Spain could not now deny the presence of the golden age, marked by security, a high and well-diversified culture and a balanced and critical civilization, which, if it produced only few statesmen, gave Rome the younger Seneca, Lucan, Martial, Quintilian, Columella and Pomponius Mela as literary or academic ornaments. The 3rd and 4th centuries saw initiative, if not prosperity, declining. City walls crumbled in neglect, through excessive dependence on Rome; and when the barbarians burst the Rhine frontier in A.D. 406-407 and flooded Gaul and Spain, there could be neither resistance nor (C. H. V. S.) hope of recovery.

With the irruption of the Vandals, the Suebi (Sueves, Suevi) and the Alani (Alans), the history of Spain enters on a long period of division and confusion. The Vandals and their associates, who plundered far and wide, were not numerous enough to establish a rule of their own. When in 428 their king Gaiseric passed out of Spain to found the Vandal kingdom of Carthage, his whole horde numbered only 80,000 persons, including old men, women and children and runaway slaves. Salvian says that many of the subjects of the empire preferred poverty among the barbarians to the

Roman capital; trunk roads were constructed (e.g., that from the tyranny of the imperial tax collectors. The great landowners had, moreover, almost as much to fear from the agrarian insurgents known as Bagaudae, who are found acting with the Suebi, as from the barbarians. In the north the Asturians and Basques, the least romanized part of the population, appear from the beginning of the age of barbarization as acting for themselves. In the mountain country of Cuenca, Albacete and the Sierra Nevada the native Orospedans were entirely independent in the middle of the 6th century. Spain was thrown back into the state of division from which it had been drawn by the Romans-with the vital difference that the country now possessed the tradition of the Roman law, the municipalities and one great organization in the Christian Church.

No help was to be expected from the empire. Unable to aid itself it had recourse to the Visigoths (see Goths). Ataulphus (q.v.), the successor of Alaric I and husband of Placidia, whom he had married against the wish of her brother the emperor Honorius, entered Spain in 414 but was murdered in 415. After the speedily ensuing murder of his murderer and successor Sigeric. Wallia (415-419), who was elected to the kingdom, continued Ataulphus' work. He destroyed the Alani and drove the Vandals and Suebi into the northwest. But then he handed Spain back to the imperial officials, that is to say, to weakness and corruption, and marched with all his people into Aquitania Secunda, which had been assigned to them by Honorius.

### THE VISIGOTHS

The Visigothic rulers of Aquitaine began to intervene in Spanish affairs early in the 5th century but it was not until 404, during the reign of Alaric II (484-507), that large-scale migration to Spain began. The migrants, who certainly did not number more than 200,000, included peasants as well as warriors and clergy and established their overlordship without serious opposition (497). In the areas where they elected to settle, the Hispano-Roman landowners (hospites) were compelled to surrender to the newcomers two-thirds of their cultivated land (sortes Gothicae), but there was no general expropriation even in Old Castile, where Visigothic settlement was densest. The political capital of the Visigothic monarchy was transferred from France to Toledo in the reign of Athanagild (551-567).

Though the invaders were both politically weak and already highly romanized, powerful influences at first prevented any rapid assimilation to the native population. The Visigoths were followers of the Arian heresy and remained subject to their own legal codes, while the Hispano-Romans were Catholics and continued to be governed by Roman law. Intermarriage between the two races was prohibited. Instability was to be the outstanding feature of the state set up by the Visigoths in Spain. Because of the ambitious Visigothic nobility's strict insistence on the principle of elective monarchy, the crown was constantly menaced by political intrigue, and the removal of the sovereign by deposition or assassination was frequent. Leovigild (568-586)-one of the few effective Visigothic kings-finally destroyed (585) the remnant of the Germanic kingdom set up by the Suebi in northwestern Spain about 175 years before and managed to bring the ever-rebellious Basques under his control; he also dealt successfully with a Catholic rebellion against the state religion. But the next king, Reccared (586-601), was baptized a Catholic soon after his accession, and the third council of Toledo then proclaimed the conversion of the whole kingdom (589).

The removal of the religious barrier allowed the assimilation of the two races to progress more rapidly, and the councils of Toledo, where nobles as well as clergy were represented, now began to dominate the crown. The reign of Swintila (621-631) saw the final expulsion of the Byzantine prefecture set up in southern Spain in Athanagild's time. In the time of Sisenand (631-636), the fourth council of Toledo-presided over by St. Isidore-completed the subjection of king and government to ecclesiastical authority. An event of great significance for the subsequent history of mediaeval Spain was the promulgation by Reccessinth (640-672) of the Liber judiciorum as the sole legal code for both races. This was a new compilation, drawn up by order of the king c. 654,

in which Germanic customary law predominated over Roman legal traditions.

It is probable, however, that the extent of the assimilation between the two races brought about by Reccared and Reccesswinth has been somewhat exaggerated. Even after their reforms only nobles of pure Visigothic descent could be elected to the throne, and the Germanic nobility was thus encouraged to maintain its racial purity up to (and after) the final fall of the monarchy.

Wamba (672-680), the last king of any stature, attempted to reorganize the decadent military institutions of his kingdom but was deposed by a trick; and the energies of the next three kings were chiefly concerned with holding their thrones against the intrigues of their political enemies. By the time of Roderick (710-711) the disintegration of the state was complete. Apparently as a result of an invitation from Roderick's opponents, Tarik, the Arab governor of Tangier, crossed the Strait of Gibraltar with an invading Arab and Berber army in 711. Roderick called for national unity against this grave threat, but even then the Visigothic nobles declined to abandon their suicidal partisanship. Defeatism was deliberately encouraged by some of them in the army that Roderick had assembled; in consequence it was routed by Tarik south of Medina-Sidonia on July 19, 711, the king himself disappearing from history.

The collapse of the Visigothic monarchy in Spain followed at once. A substantial number of members of the large slave population abjured Christianity to improve their social position. The Spanish Jews, subjected to fierce persecution since the reign of Sisebut (612-621), welcomed the tolerant invaders as liberators. A number of high Visigothic nobles accepted Arab suzerainty. Toledo fell without resistance and the invaders speedily completed the occupation of almost the whole peninsula. Though the Arabs took one-fifth of the land for themselves the Christian communities were left with their religious and legal independence intact and

were protected by Koranic law.

The social system of the Visigothic monarchy had consisted broadly of an aristocracy of nobles (primates) and clergy; a large class of freemen (mgenui) of mixed racial origin; and a numerous slave class (servi). The aula regia was made up of palace officials (palatini), who held the title of count by virtue of their offices. Provinces were governed by duces or comites and subdivided into areas ruled by judices. This stratified society without clear political ideals proved incapable of creating any sense of national cohesion during the two centuries of Visigothic rule in Spain. Though they were by no means without creative capacity in letters and the visual arts, it was as lawgivers that the Visigoths exercised their greatest influence on the history of Spain. Reccessinth's Liber judiciorum remained the basic legal code of Christian Spain for centuries after the disappearance of the last Visigothic king; and, by a curious paradox, memories of the feeble Visigothic state were now to prove strong enough to sustain the small Christian states of the north in their long and desperate resistance to Islamic military (P. E. R.) and cultural power.

## MOORISH SPAIN TO 1031

During the reign in Spain of the Visigothic king Witiza (701-709) Arab forces of the caliphate (q.v.) had conquered northern Morocco and laid siege to Ceuta, the last remnant of the Byzantine possessions. It seems certain that Julian, the imperial count or governor of Ceuta, incited the Arab viceroy in North Africa, Musa ibn Nusair, to attack Spain, possibly by arrangement with the sons of Witiza. After a successful preliminary raid by the Berber Tarif in 710, Musa ordered his governor at Tangier, Tarik ibn Ziyad, to make a descent in force. In 711 Tarik crossed with 7,000 men, mostly Berbers, and, after reinforcement by 5,000 more, awaited Roderick's advance near the Laguna de Janda, south of Vejer de la Frontera. There, on July 19, Roderick was defeated, and probably killed. The sons and partisans of Witiza, who had withdrawn during the battle, now joined Tarik and encouraged him to advance northward to seize Toledo, while a detached force occupied Córdova. In June 712 Musa crossed with an army of 18,000, mostly Arabs, captured Seville and Mérida (after a siege lasting over the winter) and dispatched his son 'Abd al-Aziz to

the southwest, before himself joining Tarik at Talavera. After wintering at Toledo, he resumed his advance in 714, captured Saragossa and made with Tarik a two-pronged expedition into León and Galicia before returning to Damascus at the caliph's command. His son 'Abd al-Aziz, after occupying Portugal, completed the conquest of Granada and Murcia, where the duke Theodomir (called Tudmir by the Arabs) became tributary. Other Arab forces pushed northeast into Septimania; and later governors continued to raid into Gaul, where, although defeated by Charles Martel at Poitiers in 732, they maintained an advanced base at Narbonne until its capture by Pepin in 751.

The invaders met little opposition on the whole. The sons of Witiza and other great Visigothic families, whether converted to Islam or not, compounded by payment of tribute for extensive domains. The Jews, freed from persecution, were eager allies, and the serfs gained a measure of freedom. Conversions were on a large scale, and the Spanish converts (muwallads) became an active and turbulent element in the general Moorish population. The unconverted, called mustaribs (Mozarabs), did not suffer much from interference and, like the Jews, formed prosperous communities in the Moslem cities. The Arabs, in spite of continuous immigration, were too few to colonize the country; they formed the administrative and military cadres, maintained by the allotment of fiefs in the region of Saragossa, the eastern and southern coasts and the Guadalquivir valley. The Berbers settled mainly in the centre and in mountainous regions which resembled their native land and favoured their anarchical tendencies. Berber revolt in Morocco in 740 produced a parallel outbreak in Spain, and Berber risings, large and small, continued for the next two centuries. Among the Arabs, also, the intertribal feud between Kais and Kalb (see CALIPHATE) was reflected in Spain, complicated by rivalries between the early immigrants (baladis) and the Syrian contingents (shamis) which came in from 741 onward. In this patchwork of racial and tribal discords, rebellion was almost endemic, and the resulting lack of unity remained a permanent characteristic of al-Andalus, as Moorish Spain was called.

The Omayyad Dynasty.—In 755 the Omayyad prince 'Abdar-Rahman ibn Mu'awiya, escaping from the massacre of his relatives in Syria, landed at Almuñécar, and with Kalbite support captured Córdova (756). He waged pitiless warfare against internal disorder for more than 30 years and established a centralized power based upon an imperial guard of Berbers and European slaves (Slavonians). The pious Hisham I (788-796) tried to stem the expansion of the Asturian kingdom. A series of muwallad revolts, at Saragossa, at Toledo, at Mérida and in Córdova, threatened to dislodge his successor, al-Hakam I (796-822), who, however, by his implacable resolution reaffirmed the Omayyad power and laid the foundations of the material and literary culture which developed under the urbane 'Abd-ar-Rahman II (822-852). The peace was again broken under Mohammed I (852-886) by successive muwallad and Berber revolts, often with Asturian support, notably those of the "Visigothic" Beni Kasi at Tudela and Saragossa and of Omar ibn Hafsun in the Sierra de Ronda. General disintegration and civil war among and between Arabs, Berbers and muwallads in all quarters forced his son 'Abdallah (888-912) to adopt a temporizing and defensive strategy.

'Abdallah's grandson 'Abd-ar-Rahman III (912–961) by resolute and far-sighted leadership lifted the kingdom from this morass to an apoge of power, culture and magnificence. Within ten years he mastered Ibn Hafsun (d. 917) and his sons, and in ten more he reunited Moorish Spain. He proclaimed himself caliph in 929, taking the title of al-Nasir (the Victorious). In spite of occasional reverses, he forced the Christian princes to pay tribute to Córdova, now a metropolis enjoying immense reputation and prestige in all Europe. He greatly enlarged the Slavonian guard, whose officers acquired increasing power at the expense of the old Arab aristocracy. The reign of his son al-Hakam II (961–976) was no less brilliant. The weakness of Hakam's son Hisham II (976–1013) favoured the rise of a military dictator, the Arab Ibn Abi Amir, later entitled al-Mansur (Almanzor) (981–1002), under whom, as under his son 'Abd al-Malik al-Muzaffar (1002–08), the military

SPAIN II7

power of the caliphate, now recruited mainly from Morocco, was at its height. But beneath the surface the old antagonisms and social discontents were still alive. In roog they broke out in a political crisis which temporarily reduced Moorish Spain to chaos and from which it never fully recovered. While Slavonians and Berbers turn by turn occupied Gordova and made and unmade caliphs, the rest of al-Andalus threw off all allegiance to the Omayyads and was dissected among a host of petty rulers (muluk al-tawaif). After Córdova itself had been occupied by the Moroccan Arab house of Hammuda (1016-27), the last Omayyad prince was dethroned in 1031 and replaced by a republic

## (H. A. R. G.)

## CHRISTIAN SPAIN TO 1479

The history of Christian Spain during the period 711-1479 is dominated by the interplay of two opposed forces: the idea of an ultimate Christian reconquest of the whole peninsula; and the inescapable fact that, both culturally and economically, the Islamic and Christian peoples of Spain had become irretrievably associated with each other. The urge to reconquer, based partly on religious belief, partly on the Visigothic tradition of Spanish unity and partly, too, on economic pressures, did not express itself predominantly through the forms of militant Christianity until four centuries after the Moorish occupation. Then, when religious fanaticism had made its appearance, among both Moors and Christians, at the end of the 11th century, the Christian conquest of Andalusia was undertaken in a spirit of intolerance that brought ruin to southern Spain and severely damaged the economy of the conquering power, Castile. Once again, however, the fact of the convivencia between the two Spains asserted itself, and fanaticism had to be moderated. Thus, in 1238, Ferdinand III, the conqueror of Andalusia, was compelled to acquiesce in the foundation of the new Moorish kingdom of Granada and to give it his protection because it was recognized that without Moorish tribute, the economic structure of Castile could not survive while it digested the newly reconquered territories. For the same reason the Christian kings had to continue to accept the existence within their frontiers of communities of Islamic vassals (Mudéjares) to whom they also gave protection.

The Kingdom of Asturias.-Before the tide of Arab and Berber invasion a number of Visigothic nobles and their retinues withdrew to the mountains of Asturias and there elected a Visigothic prince, Pelayo (?718-737), as their king. The Berber revolt in Morocco and Spain and the consequent withdrawal of the Berber garrison in Galicia (750) led to the attachment of Galicia to the new kingdom by Alphonso I (Alfonso; 739-757). Under Alphonso II (792-842) the Asturian capital was moved from Cangas de Onís to Oviedo. Later kings pushed forward from the mountains to the central plain and their armies operated with success far to the south. The supposed discovery of the tomb of St. James at Compostela in Galicia (c. 830) made the Asturian kingdom guardian of a shrine of European significance and gave it a symbol of national unity. Alphonso III (866-910), the greatest of the Asturian kings, expanded his domains as far as Coimbra in the southwest and Burgos in the southeast. By now the situation was stable enough for his successor, García I (909-914), to move the capital from the Asturian mountains to the city of León.

The Asturian kings, like their Leonese successors, regarded themselves as direct heirs to the traditions of the fallen Visigothic monarchy; and, for this reason, the historical writings of Alphonso III's reign emphasized their obligation to undertake the reconquest of all Spain. The Asturian administration followed Toledan models as closely as circumstances permitted. Yet the organization, social and political, inherited from the Visigoths was already being changed by the immigration of a free Mozarabic peasantry from the south, while Frankish political ideas also exerted some influence on Asturian society. In general, however, it can be said that the Asturian kings handed on to the kings of León a tradition of isolation, not only from Moorish Spain but also from the rest of Christian Europe, which experience was to show could not be sustained.

The Kingdom of Leon.—The transfer of the Christian capital pendent history.

from Oviedo to León coincided with the establishment of the caliphate of Córdova and, until the early 11th century, the balance of power in the peninsula swung strongly in favour of the Moors. That the Leonese kingdom survived at all was the result of the generalship of Ordono II (914-924) and Ramiro II (932-950) who, in unfavourable circumstances, secured important victories against the caliph's armies. Ramiro was, however, unable to prevent the breakaway from his kingdom of the Christian county of Castile. This district, partly recolonized by immigrants from the north, had rejected the Visigothic Forum judicum in favour of Castilian customary law and showed itself hostile in other ways to the Visigothic traditions of León until, under Count Fernán González (923-970), it achieved de facto independence. Henceforth clashes between the innovating tendencies of Castile and the conservative traditions of León were to weaken the Christians. Ordoño III of León (951-956) acknowledged the hegemony of the caliphate, and the later attempts of Bermudo II (984-999) to assert his independence of Córdova brought disaster on the kingdem. Almanzor's armies occupied and destroyed León (988) and sacked Santiago de Compostela itself (997), sparing only the Apostle's tomb. Under Alphonso V (999-1027) the capital was repopulated and recovery began. However, early in the reign of Bermudo III (1027-37), a new threat to the independence of León materialized when Sancho III the Great of Navarre, after seizing the county of Castile (1028), occupied the eastern part of the Leonese kingdom. Later he entered the capital (1034) and there assumed the title of "emperor of Spain," Bermudo fleeing to Galicia. León was never wholly to recover its supremacy again.

The Rise of Catalonia and Navarre.-During the reign of Charlemagne the Franks succeeded in capturing Barcelona (801) and in driving the Moors out of the northeastern corner of the peninsula. This area, later known as the Marca Hispanica, was then occupied by a number of Visigothic counts under Frankish suzerainty. In the time of Count Wilfred (865-898) the county of Barcelona became independent and established its hegemony over the other counties of the Marca Hispanica. Under Borrell II (954-992) Almanzor's armies devastated Catalonia and burned Barcelona (985); but the region recovered during the rule of Raymund Borrell (Ramón; 992-1018). Under Berengar-Raymund I (Berenguer Ramón, 1018-35) it began to flourish. Because of the influence of the Franks it had already developed political and social institutions different from those of the rest of Christian Spain. The 10th century also saw the dramatic rise of the Basque kingdom of Navarre, which has little history before this period. Sancho I Garcés (905-926) added the small county of Aragon to his dominions but suffered severely at the hands of 'Abd-ar-Rahman III's armies. A period of subordination to the caliphate followed, but Sancho II Garcés (970-995) was spared the worst of Almanzor's attacks and devoted himself to the political organization of his kingdom. There was, however, nothing to indicate that, under Saucho III the Great (1000-35), Navarre was to become, for a brief period, the dominant power in Christian Spain.

The Mediaeval Spanish Empire.—Though Sancho the Great had assumed the imperial title in León, his political ideas were hostile to the old Visigothic-Leonese tradition of peninsular unity, and his empire was largely built on a simple desire for personal aggrandiscment. It included Navarre, Castile, León, Sobrarbe and Ribagorza while Berengar-Raymund I of Barcelona became his vassal. Sancho deliberately encouraged contacts between his dominions and the rest of Christian Europe and probably did much to make the Spanish nobles aware of the feudal aspirations of their class north of the Pyrenees. He regarded his empire as his personal property and distributed it among his four sons in his will. The eldest, García Sánchez III (1035-54), inherited an enlarged Navarre. Castile was made a kingdom and given to his second son, Ferdinand; Sobrarbe and Ribagorza were united in a separate kingdom and given to another son, while the small county of Aragon was also erected into a kingdom for his fourth son, Ramiro I (1033-65). Ramico soon incorporated Sobrarbe and Ribagorza into his new kingdom (1037), and Aragon thus began its indeII8 SPAIN

Sancho's will provided for the return of León to Bermudo III on his death, but this restoration was overthrown by Ferdinand I of Castile (1037-65), who speedily annexed León and reoccupied (1054) the Castilian territories given in his father's will to his eldest brother, García of Navarre. Ferdinand also took the imperial title and by virtue of this claimed suzerainty over his brothers. He achieved great successes against the Moors, pushing his frontiers to the Tagus in the south and the Mondego in the west and making the taifa kings of Saragossa, Seville and Toledo his tributaries. On his death Ferdinand, as his father had done, divided his dominions among his sons, and there was a period of violent strife before the second of them, the brilliant Alphonso VI (1065-1109), succeeded to the whole inheritance. His reign brought great changes to Spain. Toledo was permanently reoccupied (1085); and soon afterward the Cid Campeador took possession of Valencia (1094). All the tasfa kingdoms paid tribute to Alphonso. There was no attempt to expel the newly conquered Moorish populations, who were promised royal protection and the preservation of their religion and customs. To give formal expression to his tolerant policy, Alphonso changed the imperial title by styling himself "emperor of the two religions." It seemed for a brief time as if these ideas might produce a genuine Hispano-Moorish civilization under Christian political control, Unfortunately the Almorávides' invasion of Andalusia (1086) soon removed the taifa kingdoms from Alphonso's control and replaced the tolerant spirit of the Spanish Moors by one of bigoted fanaticism. Meanwhile, under the influence of his wife Constance of Burgundy, the emperor allowed French Cluniac monks to get complete control of the Spanish church. The Spanish tradition of convivencia was wholly repugnant to these ardent disciples of Gregory VII's doctrine of the universal church. They forced Alphonso to modify his promises of toleration toward the conquered Mudéjares, compelled him to replace the old Mozarabic missal by the Roman and contrived to have the ancient Visigothic script of Spain replaced by the Carolingian hand in use in the rest of western Europe. These innovations brought into Christian relations with the Moors something of the crusading zeal which the French monks had found deplorably lacking and ensured that mediaeval Spain would in the future belong much more definitely to the common political and cultural pattern of mediaeval Europe. This uprooting of the traditions of the past was, however, partly responsible for the backwardness of Spanish culture for the next 150 years, while the new determination to regard the reconquest as a crusade rather than a recovery of territorial dominion in the end wrecked the Spanish economy, both Moorish and Christian.

Alphonso was followed by his daughter Urraca (1109-25), widow of Count Raymund of Burgundy; her turbulent reign cannot be followed here. She was succeeded by her son, Alphonso VII (1126-57), who gave new meaning to the imperial title by extending his influence over the county of Barcelona and by forcing Ramiro II of Aragon and García Ramírez of Navarre to accept his suzerainty. The counts of Gascony and Provence also accepted him as overlord and, at a ceremony at León (1135), attended by his new Christian and Moorish vassals, he assumed the title "emperor of all Spain." He also achieved resounding, if inconclusive, successes against the Moors, and the European prestige of the Spanish imperial court was recognized when Louis VII visited Alphonso at Toledo (1150). Nevertheless separatist tendencies in the peninsula secured another ominous victory when the count of Portugal, Alphonso Henriques, extracted from the emperor recognition of Portugal's status as an independent kingdom (1139). On his death, Alphonso VII, too, divided his realm among his sons, leaving Castile to the elder, Sancho III, and León to Ferdinand II. This new partition proved the deathblow to any future revival of the imperial idea originally inherited from the Visigoths. Castile and León now remained separated for 73 years, during which the magnates began to display in a marked degree that anarchical partisanship and resistance to royal authority which were to plague Spanish life for the next three centuries. Some important successes were nevertheless achieved against the Moors during this time. In 1212 Alphonso VIII of Castile (1158-1214), Sancho's son, supported by the armies of Aragon, Navarre and Portugal, routed the

Almohade amir of Morocco, Mohammed III, at Navas de Tolosa and so removed the last really serious Islamic threat to Christian hegemony in Spain. In an atmosphere of ever-mounting religious fanaticism the way was now open to the conquest of Andalusia.

The Rise of Aragon.-The kingdom of Aragon was brought into existence (1035) by a testamentary act of Sancho the Great of Navarre. During the rest of the 11th century it gradually encroached on Moorish territory north of the Ebro. Saragossa was captured (1118) by Alphonso I (1104-34) who, in spite of his entanglements in the internal affairs of Castile, was able to follow up this important success by occupying a large area southwest of the former Moorish capital. In 1137 Petronilla, the infant daughter of Ramiro II (accession 1134; death 1154), was betrothed to Raymund-Berengar IV, count of Barcelona, to whom Ramiro thereupon handed over the government of Aragon (1137-62). The son of the marriage, which was solemnized in 1150. Alphonso II (1162-96), formally initiated the personal union of both countries under the house of Barcelona which was to last until 1410. In 1170 an important step for the future of Aragon was taken when Alphonso made an agreement with Castile whereby the task of reconquering the Moorish kingdom of Valencia was reserved to the Aragonese crown. In exchange Aragon relinquished any claims to any other Moorish-held territory in the peninsula. During this reign, too, Aragon developed political interests north of the Pyrenees; Provence and Roussillon fell to Alphonso by inheritance. This preoccupation with French affairs proved fatal to Alphonso's son, Peter II (1196-1213) who, having added Montpellier to his dominions by marriage, became involved in the Albigensian war and was killed by Simon de Montfort at the battle of Muret (1213). His death put an end to major Aragonese political pretensions north of the Pyrenees. It is to be noted that, from 1137 to 1412, Catalonia was the dominant partner in the association of the two countries. Economically and culturally Catalonia was much in advance of isolationist and conservative Aragon, whose nobility often found itself more in sympathy with the politics of the Castilian magnates than with the bourgeois ideas of the nationalistic Catalans. Catalan was the language of the court of Aragon during the whole of this period.

During the reign of Ramiro II Navarre seceded (1134) from the Aragonese crown to which it had been united since 1076. Sancho VII of Navarre (1194-1234) tried to nominate James I of Aragon as his successor and to reunite the two kingdoms, but the Navarrese preferred Thibaut (Theobald) IV of Champagne as king (1234-53), and Navarre was thereafter ruled mostly by a succession of French princes. The little mountain kingdom nevertheless retained

most of its distinctively Spanish institutions. End of the Reconquest.—The last king of León, Alphonso IX (II88-I230), was succeeded, on his death, by his son, who was already king of Castile. Castile and León were thus finally united. The new sovereign, Ferdinand III the Saint (1217-52), at once embarked on a great series of campaigns to subdue Andalusia. These began with the capture of Córdova (1236) and culminated in the surrender of Seville (1248). Influenced by the crusading zeal instilled into the Spanish church by the Cluniac and Cistercian orders, Ferdinand at first expelled the Moorish inhabitants of the Andalusian cities en masse but was later forced to modify his policy by the collapse of the Andalusian economy that inevitably ensued. He also assented, chiefly for financial reasons, to the establishment of the new Moorish kingdom of Granada under Castilian suzerainty. The Granadine Moors were forced to create, by hard work, a high degree of productivity in their new state in order to pay to Castile a large annual tribute, which probably became essential to the well-being of Castile's finances. This reviving tendency toward a renewal of the older tolerance toward the Moors was also reflected in the cultural field; Toledo now became famous throughout Europe as a centre where Moorish philosophy and science were, under the stimulus of successive archbishops, made available in translation to European scholars. During the same period James I of Aragon (1213-76), Peter II's son, who was legislator and littérateur as well as warrior, completed Aragon's part in the reconquest. After occupying the Balearics (1235) he captured Valencia (1238) and so established the final peninsular

frontiers of Aragon. By these Castilian and Aragonese achievements the reconquest was, for all practical purposes, brought to an end. Both countries now gave themselves up to internal social and constitutional struggles.

Castile and León From 1252 to 1479.—The reign of the cultured Alphonso X the Wise (1252-84) was politically ill-fated. Alphonso involved himself in wars with Portugal, Aragon and Navarre and, having got himself elected to the German throne (1257), devoted much effort and treasure to an unsuccessful attempt to make good his claims against papal opposition. At home a constitutional struggle developed over the rival claims to the succession of Ferdinand of La Cerda and of Sancho, respectively the grandson and the brother of the king. This ended in an attempt by a junta of prelates and nobles, supporters of Sancho, to denose Alphonso (1282) and saw the beginning of an acute phase in the violent clash between the magnates and the crown which was to dominate Castilian politics for 200 years. Alphonso's legal works, based on the renascent doctrines of Roman and canon law, laid the theoretical foundations for monarchical supremacy; but the king was too inept a politician to succeed in enforcing them. The troubled reign of Sancho IV (1284-95) was complicated by war with Aragon, which supported the succession of the house of La Cerda; and Castile did not emerge from continuous civil strife until the end of the minority of Sancho's grandson Alphonso XI (1312-50). This Alphonso, aided by the armies of the autonomous municipalities (concejos), sternly repressed the magnates and succeeded in establishing a measure of absolutism which found expression in the legal and political reforms promulgated at Alcalá (1348). He also took up arms successfully against a threat from Morocco, defeating the invaders at Salado (1340).

The trend toward strong central government would probably have continued under his son Peter I the Cruel (1350-69) without major trouble, had not Alphonso left a number of powerful bastard sons to contest his legitimate heir's inheritance. The eldest, Henry of Trastamara, posing as the defender of the magnates against royal attempts to limit their ancient privileges, began a struggle to seize his half-brother's throne which lasted about 10 years. Meanwhile Aragonese designs on Murcia-Castile's only outlet to the Mediterranean-and Castilian ambitions in western Aragon plunged the two countries into a ferocious war (1356-66) which became even more embittered when Peter IV of Aragon espoused the Trastamaran cause in Castile. It was not, however, until France intervened actively in support of Peter IV and Henry of Trastamara that Peter of Castile's victories in Aragon were checked. Both France and England believed that the support of the powerful Castilian fleet might prove decisive in settling the outcome of the Hundred Years' War. Peter I's alliance with England (1362) therefore led to the dispatch of the free companies to Castile, financed by France and the pope (1365). Peter fled to Gascony and secured the military intervention of the Black Prince. who routed Henry's supporters at Nájera (1367). Peter was restored but quarrelled with his English ally, who then began negotiations with Aragon, Navarre and Portugal for a quadripartite partition of Castile. In 1369 Henry of Trastamara, again with French help, defeated and killed the Castilian king at Montiel and finally seized the kingdom (1371).

To counteract this French success John of Gaunt married Peter's daughter and heiress Constance (1371) and thus became pretender to the Castilian throne (1372–87). He was, however, mable to invade Castile during the reign of his rival Henry II (1369–79), who succeeded in consolidating his position against strong loyalist opposition. For several decades to come a close political and military alliance with France dominated Castilian foreign policy, and Castilian sea power menaced the English south coast. In spite of the conservative and class-conscious ideas of the Trastamaran monarchy, the constant wars in which they were involved compelled Henry and his son John I (1379–90) repeatedly to seek financial aid from the third estate, which thus in the latter's reign secured a considerable measure of control over the government. John brought military and financial ruin to his kingdom, partly because of new Lancastrian attempts to conquer Castile and partly because of his own ambitions to add Portugal to his

crown. His crushing defeat by the Portuguese at Aljubarrota (1385) was followed by the landing of John of Gaunt in Galicia with a large army (1386). French support and John of Gaunt's military ineptitude, however, saved the Trastamaran dynasty and the dynastic dispute was finally settled (1388) by the marriage of Catherine of Lancaster. Peter I's granddaughter, to John I's heir, Henry III (1390-1406). Violent outbreaks against the Jews marked Henry's accession. In his short reign the crown reverted with success to the policies of Alphonso XI and Peter I and reduced the magnates to order by stern measures. At this time, too, the occupation and colonization of the Canary Islands was begun. The long reign of the weak John II (1406-54) saw a continuance of the political disintegration of Castile as a result of a renewal of the struggle of the magnates with the crown. Civil war was now frequently accompanied by armed Aragonese and Navarrese interventions. John, a politically inept lover of the arts, left the government in the hands of his favourite, Alvaro de Luna. Luna's power was not broken until 1453, when the king, acceding to the demands of the nobles and of the queen, ordered his execution.

Under the impotent Henry IV (1454-74) the Trastamaran dynasty reached its lowest ebb. Civil strife continued unabated and was now accompanied by a collapse of the moral standards of the court. The king had married Joan (Juana) of Portugal (1455), but their daughter and heiress, also called Joan, was alleged to be the child of an adulterous relationship of the queen's. Opponents of the court accordingly favoured the adoption of the king's sister Isabella (Isabel) as heiress to the throne. The magnates formed a league in support of Isabella though popular opinion tended, as usual in such circumstances, to support the king. Joan's marriage to Alphonso V of Portugal and his active support of her claims led, on Henry's death, to five years of civil war before Isabella triumphed and was acknowledged to be queen of Castile by the peace of Trujillo (1479). Ten years before she had married Ferdinand, son and heir of John II of Aragon. Thus, on John II's death (also in 1479), the crowns of Castile and Aragon became associated though not yet formally united. The 15th century had so far been an age of political, financial and moral decay in Castile. There was nothing to hint, in 1474, that the central kingdom would, within a few years, become the heart of a world

Aragon and Catalonia, 1276-1479.—The conquest of Valencia having ended Aragonese participation in the reconquest, it became necessary for the eastern kingdom to expand outside the peninsula if it was to avoid becoming subordinate to the hegemony of Castile. Under Peter III (1276-85) Aragon therefore began political and military intervention in Italy. As husband of Constance, daughter of the emperor Frederick II's bastard son Manfred (see SICILY), Peter accepted the throne of Sicily and promised to free his new subjects from the rule of Charles of Anjou. In pursuit of this aim Aragonese troops and Catalan ships secured substantial successes against French military power and papal diplomacy and made Aragon a major factor in Italian politics. Papal pressure on Peter III's sons Alphonso III (1285-91) and James II (1291-1327) resulted in Aragonese undertakings to abandon Sicily; but these were not accepted by the Sicilians, and James's brother Frederick (Fadrique) was eventually recognized as king of the island of Sicily for life (see FREDERICK III). James also secured the grant of Sardinia to Aragon as a papal fief (1297), though the island was not completely subjugated until the 15th century and Aragonese claims to it led to prolonged hostilities with Genoa. Aragonese power in the Mediterranean was further strengthened by the activities of the Catalan company in Asia Minor and Greece, which eventually brought about the establishment of the Catalan duchy of Athens, first under Sicilian and then under Aragonese suzerainty. The Aragonese dynasty in Sicily remained closely associated with the Aragonese crown, and both countries were united when Martin L of Aragon (1395-1410) succeeded his son Martin 1 of Sicily in 1409. The reign of Alphonso V (1416-58) saw a further dramatic extension of Aragonese power in Italy when after a long struggle, Alphonso finally became the undisputed ruler of the kingdom of Naples (1443) and transferred his capital there

I20 SPAIN

These events reacted unfavourably on the political situation in the parent kingdom, where Aragonese and Catalan particularism grew apace and reached its climax under John II (1458-79), when Catalonia was in revolt against the crown for 11 years. The discontent of the Catalans dated back to the compromise of Caspa (1412), which had placed Alphonso V's father, the Trastamaran prince Ferdinand I (1412-76), on the Aragonese throne when the male line of the house of Barcelona had become extinct. Since 1164 Catalonia had been the dominant partner in the Aragonese union. Now the Catalans feared, with some reason, that the Castilian dynasty would favour Aragonese interests at their expense.

The preoccupation of successive kings with Italian affairs weakened the crown at home. In 1283 the nobles and municipalities of Aragon formed an union and extorted a General Privilege granting them special privileges and immunities. These were increased substantially in 1287 and remained in force throughout the reigns of James II (1291-1327) and Alphonso IV (1327-35). But in 1348 Peter IV (1336-87), who had strong absolutist leanings, routed the army of the union at Epila and put an end to an intolerable constitutional situation. Peter's reign represents something of a break with the general policy of Aragon during this period. Having annexed the kingdom of Majorca (1344), he challenged the peninsular hegemony of Castile (1356); but, in the 11 years' war which followed, a large part of his kingdom was overrun and occupied by the armies of Peter I of Castile. He saved himself by joining in the French effort to dethrone his Castilian rival and replace him by Henry of Trastamara. Henry promised to cede the whole of eastern Castile to Aragon in exchange for Aragonese support but declined to fulfil his promise when he had secured the Castilian throne. Long years of negotiation for an Anglo-Aragonese alliance against Castile followed, during which Peter IV sought to play off French and English interests in the peninsula for his own ends without finally committing himself to either side. In the last years of his reign the common problems with which the schism in the papacy faced the peninsular kingdoms led him to try to form a peninsular bloc that would be neutral in both religious and military affairs; but French pressure prevented the success of this far-sighted plan. Peter's son John I (1387-95), elder brother and predecessor of Martin I, left the conduct of diplomacy largely to his French wife Yolande of Bar, and Aragonese foreign policy became largely subservient to that of France. The accession of a Castilian prince to the Aragonese throne as Ferdinand I in 1412 had already foreshadowed the union of the two largest peninsular states, and this was made certain in 1469, during the reign of Ferdinand I's second son John II, when Ferdinand, the heir to the throne (born 1452), married the Castilian heiress Isabella (born 1452). The same year which saw Isabella undisputed ruler of Castile (1479) brought her husband to the Aragonese throne as Ferdinand II. The destinies of the two countries were thereafter bound together.

Mediaeval Institutions: Asturias, León, Castile.—The Asturo-Leonese kingdom inherited from the Visigoths the principle of elective monarchy; but in practice its sovereigns were always chosen from the same family. By the 11th century primogeniture was accepted, though the elective tradition was never formally abandoned. In accordance with their declared policy, the first Asturian kings sought to re-establish at Oviedo the civil and ecclesiastical administration which had existed at Toledo. Outlying regions were governed by comites in the king's name, and the officers of the royal household were the direct successors of the Visigothic palatini. The steward (maiordomus) and the standard-bearer (armiger regis or dapifer) eventually emerged as the chief civil and military officers of the court. By the 13th century the governorship of the larger provinces was usually held by an adelantado, who exercised regional military and judicial authority on behalf of the king. In some areas similar duties were carried out by the merino mayor. The merino menor, who was appointed by either of these two officers, acted as their deputy in matters of criminal jurisdiction reserved to the crown (voz de rey). The traditional military organization of the country was overhauled by John I of Castile in 1383 when, following

French practice, a constable aided by two marshals took over the duties previously performed in the king's name by his afférez. The office of admiral of Castile was created by Ferdinand III. The cancellarius rarely appears before the 12th century. By the time of Alphonso X, however, the chancellor was recognized to be the chief civil officer of the household. The cancilleria, like the court itself, remained ambulatory until the end of the mediaeval period. The employment by the king of a privy seal (sello de la poridad), independent of the chancery and held in the custody of its own canciller, was well established by the end of the 13th century. As elsewhere in Europe the privy seal was evidently used by Alphonso XI and Peter I to further the direct control of the king over the government since, in the political reaction brought about by the accession of Henry of Trastamara, attempts were made to restrict its use. The treasury, whose officials were largely Jewish, was headed by the almogarife mayor, later known as the tesorero mayor. Peter I created several contadores reales to supervise the work of local tax collectors.

In theory feudalism did not exist in Castile or León, the magnates (ricoshombres) holding their territorial possessions, from which their rank derived, by virtue of an individual grant for life only from the king. Vassalage was not tenurial, and lands were not held for military service. In practice, however, feudal grants did occur and, from the 10th century onward, the magnates constantly attempted to usurp feudal rights for themselves. The ambiguity of their status may, indeed, have been partly responsible for their determination to control the crown. The lesser nobles (infanzones and hijos d'algo) could be vassals of the crown or of a lord. The free peasants paid tribute for permission to till the soil either to the king on royal lands (realengos) or to a lord on seigneurial lands (señorios). On the behetrias the peasants were semifree, having the theoretical right to change their lord at will. This institution was chiefly found in those areas of Castile and León proper which had been repopulated by Mozarabic immigration during the reconquest. The serfs (solarjegos) were chiefly found on the lands of the magnates, of the military orders and of the church (abadengos). The status of the Mudejares (Moslems living under Christian protection) varied according to political conditions and to locality. The Jewish communities in the towns (aljamas) enjoyed royal protection until the end of the 14th century, when an outburst of popular fanaticism led to great massacres of Jews in Seville, Córdova, Toledo and other cities (1391) and Jewish communal life was irreparably damaged.

and Jewish communal life was irreparably damaged. The most notable institution of mediaeval Castile was the semi-autonomous municipality (concejo) comprising a town (villa) and its surrounding comarca. The rise of the concejos dates from the rith century, and they were largely brought into being by the need to attract settlers, by special privileges, to newly reconquered areas. This was achieved by the royal grant of a franchise (fuero) giving the concejo in perpetuity a large measure of control over its own affairs and its own legal code. The concejos raised their own militia and formed military associations with each other (hermandades) in defense of their interests. They were invaluable allies of the crown in its struggles with the nobles, particularly during the 14th century, when their deputies (procuradores) to the Castilian parliament (Cortes) dominated that body. The appearance of the third estate in the Cortes dates from the end of the 12th century.

In the later middle ages the king depended on the vote of the procuradores for the grant of financial aid (servicio) necessary to cover civil and military expenditure. The beavy costs of the wars of Henry II and John I increased the dependence of the king on the third estate. John I was forced to meet the severe criticisms of his policy voiced by the procuradores by creating the royal council (1386). At the beginning four representatives of each estate were appointed to the new body, and the king delegated to it (theoretically at least) many of his powers. In the 15th century the concejos themselves fell victims to the growth of the royal power and had to accept royal officials known as corregidores. A hint of impending decay had already appeared during the reign of Henry III (1390–1406) when, against the wishes of the Cortes, the king succeeded in making permanent the alcabala, a highly

SPAIN I2I

main sources of royal revenue.

Mediaeval Institutions: Aragon, Catalonia, Valencia,-In spite of their union under the Aragonese crown, these three regions retained their own separate institutions and parliaments. There was a strong tendency toward feudalism in Aragon from the beginning and grants of fiefs for military service were frequent, After the union with Catalonia, where feudalism was fully developed, the Aragonese nobility intensified its efforts to obtain full feudal rights. The smaller municipalities (universidades): were less important than in Castile partly because of the dominant position of Saragossa, Barcelona and Valencia respectively in the parliamentary representation of the popular arm. The Aragonese nobility consisted of four classes, ricoshombres de natura, ricoshombres de la mesnada (created by James 1), caballeros and infanzones. These, like the representatives of the universidades, attended parliamentary sessions by right. In Catalonia there were three classes of magnates (comtes, vescomtes and valvassors). The Aragonese Cortes, which consisted of four estates (brazos) because of the separate representation of the greater and lesser nobles, was governed by complicated rules of procedure. Redress preceded supply, and unanimity was in theory required for the approval of any measure. The Cortes also claimed the right to declare war. The most important political office in the country was that of the justicia de Aragón, whose presence at sessions of the Cortes, to which he was responsible, was indispensable. He was arbitrator between king and nobles or people when disputes arose with the crown, and his decisions were virtually final. A permanent parliamentary commission (diputación del reyno) existed to deal with finance, observance of the fueros and matters pertaining to the peace of the realm. The organization of the Catalan and Valencian corts was somewhat similar, though the former asserted a right to control all legislation. A diputació general in Catalonia performed functions like those of the Aragonese permanent parliamentary commission. In spite of the many restrictions on their powers it has been suggested that the Aragonese kings had greater de facto authority than the kings of Castile, except perhaps during the domination of the union of 1283-1348. The appointment of the justicia was made by the crown, and only the crown could initiate legislation.

A peculiar feature of Aragonese administration was the absence of intermediate authorities between the central government and purely local officials. In Catalonia, land belonging to the king was ruled on his behalf by the veguers, with subordinates known as sots-veguers or battles; both were crown appointments. The importance of Barcelona gave that city a dominant place in the life of Catalonia. It was ruled by the concell de cent though, in practice, this body's authority was normally delegated to a small concell of five persons with whom were associated the veguer and the battle. Catalan law was based on the Usatges (c. 1060), the oldest written feudal code. The kingdom of Valencia was governed by the constitution (Furs) granted to it by James I in 1239. There were wide variations in the conditions of the unprivileged classes under the Aragonese crown. The legal and economic position of the Catalan serfs (pagesos de remença) was worse than that of serfs anywhere else in the peninsula. On the other hand the Mudéjares were comparatively well treated in Aragon proper where, until the 15th century, crown and nobles appreciated their economic importance and allowed them freedom of worship and their own tribunals. The Jews, vassals of the king, were favourably treated until the 15th century when, as in Castile, their (P. E. R.) position rapidly deteriorated.

## THE "CATHOLIC KINGS"

The accession of Isabella has long been traditionally regarded as the final stage of Spanish mediaeval history. When Ferdinand succeeded to the crown of Aragon (1479), which possessed also Catalonia and Valencia as well as the Balearic Islands, the married pair ruled a larger area of the peninsula than had been united for many centuries. Though Castile remained a sovereign and independent state completely separated from the states of the crown of Aragon, the combined power of the devout and energetic

unpopular sales tax of one-tenth, which then became one of the Isabella and the subtle and unscrupulous Ferdinand (V of Castile and II of Aragon) soon sufficed to make Spain one of the leading powers of Europe.

In Castile aristocratic anarchy, rapacity and violence had reduced the whole land to poverty and taught the people to look to the crown for strong government. Ferdinand and Isabella, to whom Innocent VIII gave and Alexander VI confirmed the title of "Catholic kings," responded to the demands of their subjects by a series of measures directed to the weakening of the overmighty nobility. The rebellious nobles were first defeated in a series of battles in many parts of Castile, and all castles not entirely necessary for the defense of the kingdom were destroyed. Soon the private jurisdictions of the nobility were considerably limited and their most pretentious imitations of royal customs forbidden: The administration of the great military orders, hitherto the exclusive preserve of the nobility, was progressively taken over, with their revenues, by the crown. The feature of the royal policy that contributed most toward establishing an efficient bureaucracy was, however, the principle of depriving the nobles of their influence on the royal council, replacing them by letrados (trained civil servants steeped in the absolutist traditions of Roman law) or by ecclesiastics (owing their position to royal patronage). The nobles were also attracted to the court, where they tended to lose their local influence, to dissipate their wealth in ostentatious living and to change from powerful chieftains to obsequious courtiers under the jealous vigilance of the crown, which was indeed their only source of employment and honours. They continued too to be excluded from the Cortes, in accordance with the 15th-century custom of regarding the superior estates as no longer essential thereto. Meanwhile the number of towns represented in the Cortes, which had once been as many as 50, sank to 18; and any further enfranchisement was opposed by the privileged towns (Cortes of Valladolid, 1505). Henceforth a meeting of the Cortes of Castile consisted merely of 36 procuradores, two from each town-a number conveniently small for the exercise of royal influence. These procuradores never succeeded in asserting the principle that redress precedes supply; and the old custom whereby every procurador was bound by detailed instructions (poderes) from his town was abrogated at least as early as 1505 (probably much earlier). Henceforth they were plenipotentiaries, free to consent to any proposal of the crown. Even their legislative power was not complete, since one of the 83 laws to which the Cortes of Toledo of 1502 agreed recognized that kings possessed the power "to make fueros and laws and to interpret and amend them whereinsoever they shall think it convenient to do so." The Laws of Toro (1505) did much to remedy the diversity of laws from which Castile suffered.

In the states of the crown of Aragon the Catholic kings were unable to make any large direct increase in their power. The greater nobles of Aragon enjoyed feudal liberties and privileges almost unequalled elsewhere in Europe and kept the peasantry in abject servitude. The Aragonese Cortes with its four estates was so powerful as to reduce royal power to a mere shadow-a shadow still further diminished by the overwhelming power of the justicia mayor, who, sitting in a chair, crowned the kneeling king with the formula: "We who are as good as you swear to you who are no better than we, to accept you as our king and sovereign lord, provided you accept all our liberties and laws; but if not, The Corts of Catalonia and that of Valencia were only a degree less powerful than that of Aragon. It was only by skilful use of the church and of the Inquisition that royal power could be increased in these eastern regions of the peninsula.

The Spanish Inquisition .- The Spanish church was wealthy and powerful because the people were intensely religious and because it was largely a national institution in which no foreigner might hold office and in which the crown was supreme (papal power having been reduced almost to the vanishing point). It was, consequently, a fact of serious political importance that during the anarchy of Henry IV's reign (1454-75) the Jews gained great power and influence. They might compel-sometimes by means of their usury-their debtors to renounce the Christian religion: and Marranos (baptized Jews) often preserved their old religious faith SPAIN SPAIN

in secret. At the same time the power of the Moriscos (baptized Moors) had increased, and they were reviving ancient heresies such as the half-forgotten Manichaeism. The Catholic kings consequently consulted Pope Sixtus IV, who thereupon issued a bull (Nov. 1, 1478) authorizing them to choose two or three inquisitors notable for their virtue and learning, to whom he granted jurisdiction. The bull was put into force by a royal cédula (decree) issued in Medina del Campo (Sept. 17, 1480) ordering the establishment of the Holy Office in Castile.

As a royal instrument for the strengthening of the monarchy and the unification of the peninsula the value of the Inquisition would be difficult to exaggerate. The whole organization was completely under royal control, papal sanction being little more than a matter of form. The suprema, which controlled it, was merely one of the royal councils; and the officials of the Inquisition, from the inquisitor general downward, were the paid servants of the crown, who could appoint them or dismiss them at its pleasure Also, except for one brief period (1507–17), there was to be but one Inquisition and one inquisitor general for the whole of Spain. As far as the Inquisition was concerned the political divisions between Castile and Aragon, Valencia and Catalonia soon ceased to exist.

Furthermore the Inquisition took no account of those privileges of the nobility and those extensive liberties and franchises that had been a ceaseless embarrassment to the crown. Indeed, it was used by the crown to achieve secular aims in cases where the ordinary courts were difficult to move, or where the laws and customs of the country were used to place obstacles in the path of the advancing monarchy. The familiars of the Inquisition, exercising ceaseless vigilance in the remotest corners of Spain, may be fittingly compared with the justices of the peace who did so much to uphold the throne of Tudor England. Though frequently popular among Spaniards of pure Old Christian descent, the new inquisitorial activities met with strong protest in Aragon, where it was established in 1484. The inquisitor of Saragossa, Pedro de Arbués (1441-85), was murdered—probably at the instigation of rich Marranos (baptized Jews). Throughout the centuries the chief victims of the Inquisition were men of Morisco or Marrano ancestry. It cannot be denied that the Inquisition was guilty of abuses and cruelties in the course of its long history, but it was no more unjust or inhumane than most other courts of the Europe of its day. The traditional exaggerations about it were derived from propaganda against Spain at the time of its greatness and from the works of Juan Antonio Llorente (1756-1823), 19th-century liberals and a number of historical novelists and dramatists.1

The Inquisition was abolished by Joseph Bonaparte in 1808, restored by Ferdinand VII in 1814, abolished and restored again (1820 and 1823) and finally abolished by Maria Cristina in 1834.

The Conquest of Granada.—After a hard-fought war of more than ten years (1481-92) the last of the Mohammedan kingdoms of the peninsula fell (Jan. 2, 1492) to the Catholic kings. The long process of reconquest had occupied the energies of the many provinces of Spain and thus made itself a unifying influence. It also created the Spanish military tradition which was to dominate the battlefields of Europe for the subsequent 150 years. At the conquest of Granada the Moors were granted by treaty the most liberal rights for the exercise of their religion. But the efforts of Christian missionaries, prompted by Francisco Jiménez (Ximénez) de Cisneros, the queen's confessor, stirred the Moors to a revolt (1501) which was put down after fierce fighting and was regarded as having invalidated their treaty. They were, consequently, ordered by a pragmática (Feb. 12, 1502) to leave the peninsula under conditions so difficult that they accepted the only feasible alternative, Christian baptism. Thus all the Moors of Granada

À

became Moriscos and therefore subject, as Christians, to the Inquisition. But their Christianity became only nominal, since the overwhelming majority had neither the opportunity aor the desire to understand the Catholic faith. Attempts to instruct them failed for lack of money and for lack of priests and other missionaries able to speak to them in the Arabic language. They consequently remained an anti-Catholic and, therefore, anti-Spanish population in possession of the southeastern corner of the peninsula—of the region, that is to say, most liable to invasion from the African Moors or from the Turk.

The Expulsion of the Jews .- The tide of national enthusiasm. religious fanaticism and indignation at Jewish financial operations reached its high-water mark about three months after the fall of Granada, in a decree of March 31, 1492, which offered all the Jews in Spain the alternatives of Christian baptism or exile within three months. The emigrants were allowed to sell or take with them their goods, except that a law forbade the export of gold or silver (an exception which use of the credit system made less cruel than it would otherwise have been). The number of those who preferred exile to the renunciation of their religion has been credibly estimated at 165,000. They spread over Portugal, Italy, Greece, Turkey and North Africa, where they still speak the Spanish current in Castile at the time of their expulsion. By the middle of the 20th century their descendants (Sephardim), more than 2,000,000 in number, were spread widely over both hemispheres.

Spain in the New World .- The discovery of America (Oct. 12, 1492) was the result largely of the enterprise of Isabella, and upon her fell the responsibilities inseparable from her position as proprietress of half the world. She immediately laid down certain principles of policy that endured for centuries. The most important of these was the limitation of American trade to a single portat first Cádiz, but from 1503 Seville-which maintained a virtual monopoly, in spite of its inaccessibility, till 1717. Secondly, the control of all American trade was exercised by the Casa de Contratación (House of Trade), which rapidly developed into a huge organization for the fulfilment of three important functions: as a ministry of commerce it carried out all the ordinances about the lading of ships, the registering of cargoes, smuggling and unlicensed emigration to America; as a school of navigation it formed itself into a kind of nautical university, one of the greatest centres of mathematical and scientific research in Europe (its books were translated into many languages and used by navigators throughout the world); and as a court of law it had an extensive jurisdiction over everything that happened on its ships and over most matters connected with American trade.

The exploration of America (known always to Spaniards as lar. Indias, "the Indies") was pushed on with great speed immediately after its discovery. Diego Velázquez conquered Venezuela (1499-1500) and Cuba (1511). The famous conquest of Mexico by Hernan Cortes took place between 1517 and 1524. During the opening decades of the 16th century settlements were founded in Paraguay and Colombia. In 1513 Vasco de Balboa reached the Pacific. The Philippines were discovered in 1521 and formally occupied (1565) during the reign of Philip II, after whom they were named. The expeditions of Pánfilo de Narváez and Ferdinando de Soto (1528-42) brought the Spaniards to Fforida. In 1539 the Mississippi was discovered, and during the same year Ecuador, Bolivia and Chile were added to the possessions of the Spanish crown. Buenos Aires was founded in 1535. After nearly 20 years of war Francisco Pizarro won his victory over the Inca state of Peru (1543).

As the conquest went on, it followed the traditions of the reconquest of Spain from the Moors in the middle ages. As a consequence the natives were granted a certain amount of protection and self-government. But the grant of great estates (encomiendas) to Spaniards by the crown led to the use of native labour under conditions that often amounted to cruel exploitation, which the Spanish priest Bartolomé de las Casas exerted himself to the utmost to check. Among other measures designed to mitigate the hardships of the natives he introduced the importation (1512) of Negro slaves from Africa. The policy of Isabella, Charles V and

<sup>&</sup>quot;Thus, for example, Llorente states that the tribunal of Seville alone, in 1481, tried 21,000 accused persons and burned 2,000 of them alive and as many in edigr. He obtained these fantastic figures by adding those pardoned under an edict of grace to those accused of heresy. Carrell investigation points to the cities of the control of

Philip II toward the natives was distinguished by its humanitarianism and enlightenment. Yet it must be admitted that the good intentions of Spanish kings rarely did much more than pave the colonial hell.

The energies of the first colonists were largely absorbed in one industry: the production of precious metals. Though all mines were regarded as royal property, Spaniards were allowed quite freely to discover and to operate them, provided that they went through certain formalities such as the registering of their claims before royal officials and the swearing of an oath to bring all the precious metals they obtained to be taxed and stamped at the royal offices. The royal share, at first a large one, was fixed in 1504 at one-fifth. This royal quinto, which was rarely varied in certain parts of America, amounted to 22,000,000 maravedis (about £28,000) in 1505 and had risen to more than double that amount by 1518. These modest sums were the earnest of that vast and dazzling wealth which was soon to lure Spain on to attempt world domination. The precious metals imported into Spain before 1530 were mostly gold; after that date they were from 85% to more than 99% silver. They rose in quantity steeply till the closing years of the 16th century, reaching a yearly average of about £4,000,000. In the earlier half of the 17th century they declined almost as steeply as they had arisen.

Joanna the Mad and Philip L-On the death of Isabella (Nov. 29, 1504) her eldest surviving daughter Joanna (Juana; 1479-1555) succeeded to the throne of Castile, her father Ferdinand continuing to rule the states of the crown of Aragon till his death in 1516. Since Joanna's mental derangement (she is known as la Loca, "the Mad") had become apparent even before her accession, her Habsburg-Burgundian husband Philip the Handsome, son of the emperor Maximilian I and archduke of Austria, ruled in her stead as Philip I of Castile till his sudden death (Sept. 25, 1506). Thereafter Castile was governed by Jiménez (who became a cardinal and inquisitor general in 1507) and by Ferdinand, Joanna having been persuaded to retire to a life of seclusion at Tordesillas. On the death of Ferdinand (1516) the whole of Spain, which now included Ferdinand's recent acquisitions-Cerdana (Cerdagne) and Roussillon (1493) and Spanish Navarre (invaded 1512; incorporated with Castile 1515)—came under the governance of Charles I, better known as the emperor Charles V. This eldest son of Joanna the Mad, who ruled in her name, inherited not only the Aragonese and Italian possessions of his grandfather Ferdinand but also the great possessions in the Netherlands and central Europe of his Habsburg grandfather Maximilian.

### THE HOUSE OF AUSTRIA

Charles V (1516-56) .- Charles arrived in Spain an unprepossessing youth (Sept. 19, 1517) surrounded by grasping Flemish favourites and unable to speak Spanish. By his reckless promotion of Flemings he offended the Spanish nobility; and by his demands for money he offended the common people, who were also alarmed at his obvious intention of ruling Spain as an absentee. The general discontent found expression in the revolt of the comuneros-a rising chiefly interesting for its constitutional not to say democratic character. Fortunately for Charles a rift soon showed itself between the common people and the nobles, whose support he was able to attract. As a consequence the royalists were able to win the battle of Villalar (April 23, 1521), a small fight that had great results. The comunero movement, which had once looked so formidable, collapsed at once, and the king of Castile emerged with fewer constitutional limitations than ever before.

Charles was compelled by the geography of his vast European dominions to be the enemy of France, a state which, though apparently weaker, had the advantage of fighting on interior lines while Charles's government was almost overwhelmed by such serious preoccupations as the Lutheran revolution in the empire and the powerful onslaughts of the Turk. Nonetheless, Charles's invincible Spanish soldiers won resounding victories, such as that at Pavia (1528); and the Spanish people, when they saw Francis I of France brought a prisoner to Madrid, were almost reconciled to their king's international outlook. What lay nearer to their hearts

was Charles's successful expedition against Tunis (1535) and his attempt, though unsuccessful, to take Algiers (1541). Before his abdication in 1556 Charles had taught the Spaniards to regard his interests as their own and to pour out their wealth with almost reckless prodigality for his purposes. It has been well said of him that he was born a Fleming and grew up to be a Spaniard.

Philip II (1556-98) .- Philip II, having inherited all his father Charles's dominions except the empire, which went to his uncle Ferdinand, was able to be a more truly Spanish king than Charles had ever been. The main purpose to which he devoted his life was the unification of the whole of the peninsula under his rule and the establishment of social justice among all his subjects. To say that he strove for the supremacy of the Catholic faith is only to say that he was a typical 16th-century statesman in his belief that political unity could not exist apart from unity in religion. In pursuance of these purposes he strengthened the Inquisition to enable it to stamp out the first sparks of Protestantism, which appeared in Valladolid and Seville (1559); he managed to get possession of the kingdom of Portugal (1580)-by far the greatest success of his reign, bringing indeed not only the whole Iberian peninsula under a single sceptre for the first time in nine centuries but also the second largest colonial empire in the world into union with the largest of them all, as well as securing to Spain the Atlantic harbours of Portugal and fleets manned by crews of unequalled experience; and he took advantage of a rebellion on behalf of his treacherous secretary, Antonio Pérez (q.v.), to reduce the liberties of Aragon (1592) so that that kingdom became hardly less monarchical than the other states of the peninsula.

Many modern writers repeated the views of L. von Ranke (The Ottoman and the Spanish Empires in the Sixteenth and Seventeenth Centuries, Eng. trans., London, 1843) that these changes converted Aragon into a virtual despotism. It is necessary, therefore, to point out that the changes made, though numerous, were comparatively small. Philip was too much a Spaniard to harbour the design of levelling out all local independence; he merely desired to give the central government enough power to do away with the most glaring social injustices. Among the chief acts of Philip II's Cortes of Tarazona (June 15, 1592) were the change of the office of justicia from a life appointment to one terminable at royal pleasure; and the increase in the royal share in the appointment of the justicia's lieutenants. In the Cortes itself the constitutional theory that all members of every estate (brazo) must be unanimous before a measure could become law-a theory that had long been circumvented in practice, since otherwise it would have required a miracle to pass any law whatsoever-was now definitely abrogated. The time that might be spent on statements of grievances (grueges), which had previously been theoretically infinite-to the great delay of public business-was now brought within tolerable limits. The right to seats in the Cortes was also considered. Henceforth only eight of the higher nobles were allowed to claim as a right their summons to the Cortes, and lesser nobles could only sit when the king chose to summon them; and in the same way certain towns were recognized as having the prescriptive right to send representatives, while the king was given the right, after the manner of the Tudors in England, to choose as many others as he thought fit. Such changes as these were obviously moderate and reasonable. They left Aragon with the bulk of its constitution and its ancient rights, liberties and fueros only slightly restricted in favour of the crown.

There is little doubt that the mass of the Aragonese benefited greatly from these changes in the customs of their country. They were often hideously oppressed by the aristocratic possessors of liberties and fueros. Subsequent experience would lead one to regret that Philip had not been more radical in his demand for their suppression. Thus, for example, Aragonese serfs were frequently put to death at the mere arbitrary orders of their masters; and when the crown, with characteristic zeal for social justice, inquired into these incidents the council of Aragon pointed out that there was nothing to be done, as the killing of peasants by nobles was quite in accordance with the much-prized fueros of the kingdom.

But Philip's responsibilities outside Spain were world-wide in

extent and virtually limitless in the expenditure that they demanded. Charles V's unhappy decision to attach the Netherlands to the Spanish monarchy involved his son in a rebellion that he was unable to quell after 30 years' continuous effort. The war with France, which had lasted from his father's reign, was ended at the peace of Cateau-Cambrésis (April 2, 1559), but the wars of religion gradually induced him to come to terms with his former enemies the Guises and to help them with men and money; and finally to attempt to win the crown of France for his daughter Isabella Clara Eugenia. In these plans for France he was foiled by the more able and less scrupulous Henry IV. With England Philip tried to continue under Elizabeth I the friendship that had existed under his wife Mary 1 Tudor. But the raids of English pirates upon Spanish trade with America and Elizabeth's persecution of Roman Catholic missionaries and her assistance to the rebels in the Netherlands caused strained relations between Eugland and Spain and the consequent sending of the Armada (q.v.)

Philip's position in the Mediterranean demanded ceaseless war against the Turks. But it was not till 1567 that, recognizing the grave danger present in the pro-Islamic sympathies of the lately converted populations of the south, he issued the severe pragmatica that forbade all Moorish or Mohammedan practices under pain of the heaviest penalties. The 3½ years of fierce rebellion that followed resulted in a fearful outpouring of blood and treasure and in the transportation of the entire Morisco population of Granada to northern Spain, where the Moriscos were forced to live only in houses sandwiched between those of Old Christians. Then Philip's bastard half-brother Don John of Austria defeated

the Turks at Lepanto (Oct. 7, 1571).

Lepanto has been condemned as a barren victory, yet it was regarded throughout Europe as the finest feat of arms of the century, Miguel de Cervantes says of one of the spurious continuators of Don Quixote "what I cannot forbear resenting is that he upbraids me with being maimed . . . as if my wound had been got in some drunken quarrel in a tavern and not on the noblest occasion that past or present ages have seen or future ones may hope to see"

(introduction to the second part of Don Quixote).

The expenses of Spain's great enterprises were, however, beyond anything that even the vast silver imports from America could defray; and the industries of Castile were by now being taxed out of existence. At the same time the great imports of silver from America were causing Spanish prices to rise so steeply as to destroy the export market. Hence the economic decline of Spain was far advanced before the end of Philip's reign, during which there were three virtual declarations of bankruptcy upon debts to foreign bankers: one at the beginning, one in 1576 and one in the last year (1598). Yet in Spanish historical tradition the reign of Philip II passes for an era of great successes and glory. enemies of Spain-notably Elizabeth I of England-quailed before this strength. The growth, moreover, of literature, art and science in many forms under Philip II gave Spain for a time the cultural and intellectual hegemony of the world. This growth owed at least a little to Philip's patronage and interest and may fairly be regarded as a compensation for his failures.

Philip III (1598-1621) .- In territorial extent Philip III's empire was the greatest in recorded history. Philip, born April 14, 1578, was the fourth son of Philip II's fourth marriage. He departed from the traditions of his father by employing a chief minister to carry on the government and by giving much of his confidence to members of the high nobility. The chief minister, Francisco Gómez de Sandoval y Rojas (1552-1623), duke of Lerma, was loudly and probably not without some measure of justice accused by his enemies of piling up a vast fortune for himself and his own favourites at the expense of his overtaxed country. Lerma not only found that Philip II had left an enormous debt and almost all the revenue pledged in advance to moneylenders but also had two major wars upon his hands. He was therefore driven to the last resort of destitute statesmanship, the debasement of the coinage, a measure that drove the silver currency out of the country. In one respect Lerma deserves credit: by his able diplomacy he secured peace with England (1604), the 12 years' truce with

the Netherlands (April 9, 1609) and the friendship of the French government after the assassination of Henry IV (1610). An act of more doubtful statesmanship was the expulsion of the Moriscos (1609-14). The Moriscos, however, though treated not without consideration after the resettlement under Philip II, had remained Mohammedan at heart; and it is probable that their hostility to the state was so deep-rooted and their relations with foreign powers so dangerous as to leave no feasible alternative except expulsion. The fall of Lerma (Oct. 4, 1618) was an event of no advantage to Spain, for his son and successor, Cristóbal Gómez de Sandoval y Rojas, duke of Uceda, took the fatal step, through Ambrose Spinola's campaign in the Palatinate, of involving his country in the Thirty Years' War, a step which destroyed all possibility of economic recovery.

Philip IV (1621-65).—As a patron of dramatic art and painting Philip IV was one of the most successful kings in recorded history. The plays and pictures that owe their existence dargely to his encouragement are among the world's most precious possessions. Yet from the military and economic point of view his region is to be regarded as one of the most disastrous in Spanish history,

Having come to the throne at the age of 16, Philip appointed as his chief minister Gaspar de Guzman (b. 1587), count of Olivares (q.v.) and first duke of San Lucar, known as the countduke (conde duque). An energetic, patriotic and truculent-looking man, Olivares set to work to restore Spain to its former powerful position in the world by curbing extravagant living and idleness and by changing the country from a bundle of independent states into one centralized Castilian monarchy, a plan not uninfluenced by the example of Richelieu's work in France. "You should not be content," he advised Philip IV, "to be king of Portugal, of Aragon and of Valencia and count of Barcelona, but you should direct all your work and thought . . . to reduce these realms to the same order and legal system as Castile. If your majesty succeeds in this you will be the most powerful prince in the world." an aim was unfortunate in coming at a time when Castile, the centre of gravity in the Spanish monarchy, was growing weaker in comparison with the other states, which had centrifugal tendencies. When, therefore, Olivares pushed his centralizing policy on with his habitual tactlessness and violence he was to be met with a crop of revolts of which the French were not slow to take advantage.

The early years of Spain's participation in the Thirty Years' War were marked by military successes that recalled the great days of Spanish victories. Don Fadrique de Toledo destroyed the Dutch fleet off Gibraltar; and more important still was Spinola's capture of Breda aften a ten months' siege (1624-25)—an achievement made immortal by the painting of Velazquez. The Dutch were overcome in South America and expelled from Guavaquil and Puerto Rico; and at the same time Moorish pirates were almost swept from the Mediterranean. The fever of glory and conquest had laid hold of Spain, and the name of the king became "Philip the Great"; but the demand for money followed in the footsteps of war. Olivares felt that the eastern states of the peninsula, Aragon, Catalonia and Valencia, used their three close-fisted Cortes to evade their fair shares of the burdens of the empire while loyal Castile bore all, including the greater part of the fighting. He therefore went out of his way to show them the scant respect that he considered their due.

The three Cortes were convened for Jan. 1626; and the king promised to be present at each and to take the oath as sovereign to respect their rights. The Valencians, however, resented the summoning of their Cortes at Monzón, a place outside the kingdom of Valencia, and were ready to take offense before the meeting. When the king asked them at Monzón to grant him 2,000 paid troops to be used as he pleased, as well as a money vote, they refused. It would, they said, be the same as the conscription in Castile, and that was against their liberties. Olivares alternately threatened and bribed and the king himself tried persuasion. At last he formally said that they must vote the supplies without more ado. But the noble estate of the Cortes continued to hold out against stronger pressure.

At last the king called them traitors and gave them one day in

which to do his bidding. It was necessary that the vote should he unanimous, and under this pressure all the members gave way except one-Don Francisco Millan. When, however, a hint was given that the garrotte would probably be the recompense for his obstinacy, he acquiesced in the vote. Even so the nobles still cavilled about the amount of their quota and only after much deliberation settled that the vote of money should be reduced to 1,080,000 livres in 15 years, half the sum paid by Aragon, not in coin, but in kind. The king was forced to accept, but the Cortes was discontented and would not formally ratify the vote. At length the king sent it a message that he gave it half an hour in which to vote the supply, as he was leaving at once. He then took out his watch and said that the half-hour had already begun. The Cortes, thrown into consternation by such a course, deliberated all night. But at last, at 6 A.M., the king sent a message to say that he had determined to abolish the privilege of némine discrepante (unanimity). The astonished and indignant Valencian Cortes then allowed all its resistance to collapse. The king met the Catalan Cortes at Lérida and sought to dazzle it by feasts and splendour, but the Catalans insisted on the repayment of former loans by the king before they would grant a ducat. As they would not yield to threats, Olivares, fearing mischief, suddenly and without warning carried the king back to Castile. The Catalans thereupon voted all that was required of them in the hope of getting the king to come back. The reply was a threat of vengeance for their undutifulness.

In 1639, however, when Richelieu sent French troops into Spanish Roussillon, the Catalans fought loyally and successfully for their province against the invaders. But the Castilians sent to reinforce them behaved so atrociously that in June 1640 the Catalans broke into revolt. Catalonia remained for 16 years a province of France rather than of Spain. It was to return to its allegiance to Philip IV out of dislike of the French rather than as a result of any prowess of Spanish arms. In December of the same year (1640) a well-planned revolution in Lisbon led in turn to the independence of Portugal, which Spain was unable to recover in spite of an exhausting struggle of nearly 28 years (1640-68). As a consequence of these revolts Olivares was overthrown by a court intrigue (Jan. 1643) and succeeded as chief minister by his sister's son Don Luis de Haro.

The earlier actions of the Thirty Years' War had shown that Spanish soldiers had not lost their old quality; but the French victory at Rocroi (May 1643) was not only a decisive defeat of Spanish arms but also the final invalidation of those Spanish tactics that had dominated the battlefields of Europe for nearly 150 years. Though the peace of Westphalia (1648) at last ended the Thirty Years' War, it brought no peace to Spain, with which France remained at war. It was only the Fronde in France that enabled Philip IV to struggle on till the peace of the Pyrenees in 1659, when Cerdaña and Roussillon were ceded to Louis XIV, who next year married his cousin Marie Thérèse (Maria Teresa), Philip's daughter by his first wife, Elizabeth of France. By this time the erysense of wars combined with the misgovernment of a corrupt and far too numerous civil service had brought Spain to that lowest point of economic decadence toward which it had been moving with increasing speed for nearly a century.

Charles II (1665-1700).—The fruit of Philip IV's consanguineous second marriage (1649)—with his sister Maria Anna's daughter Mariana (sc. Maria Anna also), whose father was yet another
Habsburg, the emperor Ferdinand III—the last king of the house
of Austria, was so infirm in body and in mind that he was unable
to take much significant part in the government of his dominions.
Since Charles II succeeded his father in his fourth year his mother
ruled in his name as regent, strongly opposed by Philip IV's popular and ambitious bastard son, Don John of Austria. Mariana
used as her chief ministers first the German Jesuit Johann Eberhard Nithard and then the Granadine adventurer Fernando de
Valenzuela. But these were one after the other driven from power
by Don John, with the help of his faction of the grandees.

Finally Don John became strong enough to force Mariana into a convent and to persuade the king to marry Marie Louise of Orléans (Aug. 1679) in the interests of France. But Don John

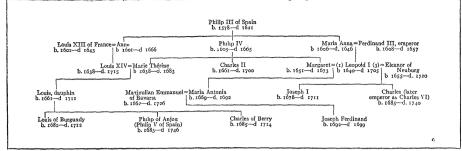

in power was a disappointment to his adherents. On his death (Sept. 1679) Mariana and the Austrian faction resumed their control of the king; and on the death of Marie Louise (1689) they induced Charles to marry Maria Anna of Neuburg, daughter of Philip William of Palatinate-Neuburg and sister-in-law of the emperor Leopold I, in the interests of the Austrian claimant to the Spanish succession. The passive Spanish domain was now the bone of contention of the powers of Europe.

While Spain was barely governed at all under the infant Charles and his capricious mother its financial and economic position became almost unbelievably bad. Crowds of reckless civil servants spread havoc everywhere. Corruption of public officers at home and abroad continued to keep the national treasury bankrupt, however crushing was the weight of taxation upon the people. Manufacturing, except for a few coarse articles for immediate home consumption, was virtually dead. Idlers and discharged soldiers, vagabonds and rogues of all sorts swarmed in the cities and about the court, but working hands were so few that even the poor harvests still raised in northern and central Spain were gathered in by French labourers who returned home again with their wages in their pockets. The trade and industry in Madrid, such as they were, were carried on almost exclusively by Frenchmen of whom there were 40,000 in the capital, mostly calling themselves Flemings and Burgundians in order to escape the differential taxation imposed upon Frenchmen. The total revenues of the crown of Castile on the accession of Charles II are given by a contemporary writer, Alonso Núñez de Castro, in Solo Madrid es Corte (Madrid, 1669), as amounting to 15,750,000 ducats derived from a great variety of sources. Of all this sum, 8,500,000 ducats are said to be pledged; in any case not more than a third would ever reach the treasury. The average amount received from Aragon, Valencia, etc., appears to have been 2,000,000 ducats, and the average annual revenue from the Indies, derived from a royalty of one-fifth of the precious metals mined and other tributes, is set down in the anonymous Relation de l'estat et gouvernement [d'Espagne] (Cologne, 1667) at 1,500,000 ducats. It is probably not far wrong to estimate the national income-apart from the royal patrimony, which was now mostly pledged or alienated-at about 9,000,000 ducats (of debased copper) actually encashed. The cost of the royal establishments reached the sum of 1,700,000 ducats a yearabout one-fifth of the whole amount received into the national exchequer. The ecclesiastical revenues of the kingdoms of Castile alone amounted to 12,000,000 ducats and the entire revenues of the same kingdoms, clerical and lay, are stated at 113,000,000 ducats. If this really was the case, taxation would not seem to have been so onerous as the complaints would lead us to believe; but since much of the land was now out of cultivation and the country depopulated, it is certain that the income was far inferior to that stated as the nominal value. It will be readily understood from these statements that Spain was in no position to undertake an adventurous foreign policy.

But the restless ambitions of the French king Louis XIV left Charles's dominions small chance of peace, whether in Flanders or in the Mediterranean. Louis fought a series of wars (1667-68, 1672-78, 1683-84; see France: History) with the object of annexing portions of them. Complications with the English and with the Dutch led, however, to the frustration of Louis's plans and to the attempts by William III of England to deprive France of the whole of the Spanish inheritance by means of partition treaties, in which the Spanish people were not consulted. Charles II, anxious above all to preserve the unity of the Spanish empire, made his will leaving the whole vast inheritance to Louis XIV's grandson, Philip of Anjou. Having signed it he died on Nov. 1, 1700, in the 40th year of his age and his 80th to judge from his appearance. The last of the house of Austria, he left Spain exhausted and bankrupt. (R. T. D.)

# THE SPANISH SUCCESSION

The military and naval history of the War of the Spanish Succession is outlined in the article Spanish Succession, War of the It may be useful here to examine how the conflict arose. The accompanying genealogy shows the descent of the principal claim-

ants of the succession.

Philip III's two daughters, Anne and Maria Anna, had married, in 1615 and in 1631, Louis XIII of France and the future emperor Ferdinand III respectively; and two sons of these marriages, Louis XIV and Leopold I, married their Spanish cousins, Philip IV's daughters Marie Thérèse and her half-sister Margaret, in 1660 and in 1666 respectively. Marie Thérèse explicitly renounced her claim to the Spanish succession on her marriage to the French king, as her aunt Anne had done; but Margaret made no such renunciation and was moreover named in Philip IV's will as the next heir after his son Charles. Consequently, when Maria Antonia, daughter of Margaret and wife, from 1685, of the Bavarian elector Maximilian Emmanuel, gave birth in 1692 to a son, the electoral prince Joseph Ferdinand, this prince could be regarded as heir presumptive to his great-uncle Charles II of Spain. Leopold I, however, had persuaded his daughter Maria Antonia to bestow her right to her mother's succession on him and on the sons of his third marriage; but the validity of this bestowal, on which the immediate Habsburg claims to the succession were based, was dubious. Also dubious, at the same time, was the Bourbon claim, based on dis-

regard of the French queens' acts of renunciation.

In the precarious lifetime of Charles II, French influences within Spain itself were heavily counterbalanced in the field of international politics by the attitude of the maritime powers. and the United Provinces, now in personal union under King William III, were strongly opposed to the Bourbon claim, fearing not only the aggrandisement of French power that would result from its success but also the loss of their well-established trade with Spain and the Indies. In Oct. 1698, therefore, Louis XIV and William III agreed, in the first partition treaty (signed at The Hague), to recognize Joseph Ferdinand's rights to Spain, the Netherlands and the Indies. Milan, however, was to go to the archduke Charles, the emperor Leopold's younger surviving son (who would presumably be excluded from the imperial throne by his elder brother); and the rest of Spanish Italy, as well as the Basque province of Guipúzcoa, was to go to the dauphin Louis. Spain was indignant at this partition, and in Nov. 1698 Charles II retorted to it in a will that named Joseph Ferdinand as heir to the whole succession, thereby giving the Bavarian claim a final authority independent of the partition treaty (which moreover the emperor had not approved). But in Feb. 1699 the child Joseph Ferdinand died, and new negotiations were urgently required. The second partition treaty, signed by France, England and the United Provinces in March 1700, offered Spain, the Netherlands and the Indies to the archduke Charles (the dauphin was to get Spanish Italy except Milan, instead of which he would have Lorraine); but the emperor declined to accede to it, hoping to win the whole succession for the archduke in reward of refusing to divide it. To counter this new partition, Charles II made his last will, leaving the Spanish dominions, which were to be kept separate from any other crown and undivided, to Philip, duke of Anjou, second son of the dauphin Louis; failing Anjou, to his younger brother Charles of Berry; failing Berry, to the archduke Charles.

Charles II died on Nov. 1, 1700, and Louis XIV was now con-

fronted with a dilemma. If he accepted the whole succession for his grandson, he would be violating the partition treaty; if he stood by the treaty, the will would prescribe exactly what the treaty had been intended by France to prevent—the passing of the whole succession to the Habsburgs. He chose the former alternative, acknowledging Philip of Anjou as Philip V of Spain. The War of the Spanish Succession ensued. (X.)

#### THE BOURBON DYNASTY

Under the treaty of Utrecht (q.v.), which ended the War of the Spanish Succession in 1713, Philip of Anjou was recognized as king of Spain but lost Gibraltar and Minorca to the English, the Spanish dominions in Italy and Flanders to the Austrians and Sicily to Savoy. To this extent the hopes that had led Charles II to appoint Philip his heir were falsified, though there were compensations. After two centuries Spain in Europe was at last driven back upon itself and given a stimulus, long sorely needed, to put its own house in order. The change in dynasty brought too a radical revision of the whole intellectual background, French taste and French ideas gradually percolating the upper classes of society and changing the course of political thinking and of literature. The Bourbon theory of state was no less absolutist than that of the Habsburgs had been, but it rested on a much more enlightened conception of responsibility and worked efficiently (in the early reigns) through ministers, not corruptly through favourites drawn from an effete pobility.

Philip V (1700-46).—In internal affairs the years of the war were of capital importance in Spanish history in spite of the confusion of a country bitterly divided in its loyalties and overrun by foreign armies, with its capital repeatedly changing hands and the constant levies on manpower and economic resources a running score. The general political and administrative nullity of the Spanish upper class of this generation and the political views of the French monarchy led to the assumption of all real power by the French and, later, the Italian servants and advisers of the king. French economists, Jean Orry and Michel Amelot, marquis de Gournay, became ministers of finance, and Marie Anne de la Trémoille, princesse des Ursins, sent by Louis XIV to counsel the child-queen Maria Louisa of Savoy, was before long the mov-

ing spirit behind the throne.

Under such direction important financial and administrative reforms were begun, notably in the collection of the national revenue, which Orry had found in 1701 to amount to little more than one-half of normal expenditure. The Cortes of Castile, in which those of Aragon and Valencia (1709) and of Catalonia (1724) were successively merged, was summoned four times only during Philip's long reign, to hear and approve royal decisions. The votting of subsidies, the original basis of their power, continued to be vested in small permanent commissions. In central government, under the chief organ, the consejo real, more direct responsibility attached to the secretaries of the subordinate councils (state, grace and justice, war, navy and the Indies, finance, was the normal distribution). From 1714 these were called ministers, foreshadowing the modern cabinet system born in 1787 with their de-

liberation in common as a council of state.

The absolutist and centralizing nature of some of these innovations exacerbated the separatist tendencies of the northeastern regions, which had embraced the Austrian cause against the Bourbon dynasty Philip was forced to reduce Aragon, Catalonia and Valencia by arms. The Catalans had relied on assurances from England and from the emperor that their fueros would be secured to them in the general peace. Deceived in this, they tought on desperately on their own, and Barcelona was only taken in 1714. the year after the signing of the treaty of Utrecht, when the city had been reduced to a shambles. Most of the privileges of these kingdoms now disappeared, those of Aragon and Valencia in 1707; those of Catalonia (exemption from conscription, the right to a separate coinage and some part of its penal law surviving) in 1716 The University of Barcelona was removed to Cerveia, and the use of Catalan was forbidden in courts of justice. The Basque province), which had sided with Philip, retained their fueros With this exception the writ of Castile now ran throughout Spain as never before, and Philip, dividing the country-formerly a composite of traditional "kingdoms"-into provinces each under a captain general, set about imposing a new unity of administration. Municipal councils, office in which had become purchasable and hereditary, were again made elective and required to submit their accounts annually to and to deposit all surplus moneys with the crown. The promulgation in 1713 of the Salic law, intended to ensure that Spain should never again fall to the Habsburgs through marriage, was to play an unexpected part in the outbreak of the First Cailist War more than a century later.

Maria Louisa of Savoy died in 1714, leaving three sons, Louis, Philip (who died young) and Ferdinand, and Philip V was straightway married to Elizabeth Farnese (q.v.), the duke of Parma's daughter, who ruled him thereafter and, exploiting his desire to follow a policy independent of France, dragged him into a series of adventures aimed at securing Italian dominions for her own offspring. The princesse des Ursins she repaid for her part in the match with instant dismissal Giulio Alberoni, an Italian priest, became head of the government, and for the remainder of the reign the queen's Italian ambitions menaced the peace of Europe and Spain's prospects of recovery. France and England threatened war in defense of the terms of Utrecht. Alberoni, spinning a web of intrigue in half the courts of Europe, was undaunted. He occupied Sardinia in Nov. 1717 and landed 30,000 troops in Sicily in the following July. England acted without declaration of war and destroyed the rising Spanish navy off Cape Passsero in August. General hostilities followed. Spain tried to send an expedition to aid the Jacobites in Scotland (1719), a French army overran the Basque provinces, English warships wrought havoc in Galicia, the emperor regained Sicily. Alberoni, made the scapegoat, was banished in Dec. 1719. By the peace of 1720 the emperor formally renounced his claim to Spain; Philip renounced his to the Austrian territories in Italy (including Sicily); and the succession of Elizabeth Farnese's issue to Tuscany and Parma was acknowledged.

Philip, increasingly a prey to religious melancholia, began in 1721 the construction of the vast La Granja palace, at San Ildefonso near Segovia, planned to remind him of Versailles; and there he withdrew almost entirely from the conduct of affairs. In Jan. 1724 he abdicated in favour of his eldest son Louis (Luis) I, whose death in August caused him reluctantly to resume the crown. An estrangement with France over the succession to the sickly Louis XV brought a momentary rapprochement with the emperor Charles VI, but this cooled even before the seizure by imperial troops of the duchy of Parma on the death of the duke, Antonio Farnese, in Jan. 1731. English diplomacy effected the cession of the duchy to Elizabeth Farnese's eldest son Charles. Spain had made great sacrifices to achieve so much of her ambition, but there was more to come. In 1733, the emperor being occupied by the War of the Polish Succession, Spain signed the first "family compact" with France, declared war on Austria and overran Naples and Sicily, of which territories Charles was crowned king in 1733, relinguishing Parma and Tuscany to the emperor.

Gibraltar was a continuing bone of contention with England.

Another, even more acute, was English contraband trade with the new world, greatly facilitated by the trading privileges won at Uttecht. Wat broke out in 1739, and Portobelo on the Caribbean was sacked by the English. The conflict merged soon after in the War oi the Austrian Succession, in which Phillip appeared in the strange tole of claimant to the empire. The second "family compact" (1743) was the prelude to much fighting in Italy, Elizabeth Farness being set now on winning territories for her second son, Philip. On July 9, 1746, Philip V died, almost insane. For more than 40 of the 46 years of his 1eign Spain had been at war. His government had been largely French, then largely Italian, with power very rarely in his hands and Spanish interests very rarely in the forefront. More positively, Spain had begin at last, with José de Patiño and José del Campillo, to produce statesmen of its own, who needed only peace to show the nation's powers of recuperation.

Ferdinand VI (1746-59) .- Ferdinand, Philip V's third and only surviving son by his first wife, was modest and retiring and much under the influence of his Portuguese queen, Barbara of Bragança, who like him was wedded to a policy of peace. This was the great novelty of the reign. At the end of the War of the Austrian Succession, the treaty of Aix-la-Chapelle (Oct. 18, 1748; Spanish accession Oct. 20) confirmed England in the commercial privileges that it enjoyed in the new world (the South Sea company was two years later, under the treaty of Madrid, Oct. 5, 1750, to receive £100,000 in compensation for the annulment of the asiento treaty) and assigned the duchies of Parma, Piacenza and Guastalla to the infante Philip (with reversion to their previous possessors should he succeed his brother Charles in the Two Sicilies or in Spain). Ferdinand henceforth steadfastly rejected the competitive blandishments of France and England alike, unmoved even by offers of Gibraltar or Minorca. Cenón de Somodevilla, marqués de la Ensenada (q.v.), and José de Carvajal, his two great ministers, though inclining respectively to France and to England, were Spaniards first and made of the national recovery their major concern. Ensenada, following in Patiño's footsteps, did much to revive agriculture, to stimulate commerce and mining and to strengthen the navy. Fiscal reform and improved communications were other factors in the restoration of a bankrupt country to comparative prosperity. Between the beginning and the middle of the century the population of Spain had risen from 5,700,000 to 7,500,000. In the general spread of enlightenment, exemplified since the change of dynasty in the proliferation of academies and other learned bodies, two details were significant of the new national temper. One was Ferdinand's attracting of foreign scholars and craftsmen to Spain; the other the profound modification in the character of the Inquisition. Under Philip this had continued active, holding 782 autos-da-fé and imposing 14,000 sentences during the reign. Under Ferdinand its vigour and rigours were much relaxed and it was no longer an instrument of state policy.

Foreign policy was marked by a series of treaties all aimed at the peaceful settlement of possible motives of discord: fronter issues with Portugal and with England in America (both 1750); the neutrality of Italy, under an agreement with Austria, Tuscany and Parma, which Naples, still reflecting the ambitions of Elizabeth Farnese, refused to sign (1752): rights of ecclesiastical patronage in Spain, settled in Spain's favour by a concordat (1753). Ferdinand's death, childless, in 1759 brought to an untimely end the country's first substantial respite from war for more than a century. The heir to the crown, Ferdinand's half-brother Charles, had already, from his kingdom of Naples, which he now resigned, proved a disturbing influence in Ferdinand's policy of peace and welcomed the wider sphere for action.

Charles III (1759–88).—Charles III was one of the most sincere and one of the most successful of the "enlightened despots" of the 18th century; for Spain he was the last. He came to Spain, aged 43, after a long apprenticeship to kingship and laboured unceasingly to advance the country's material prosperity. Widowed within a few months of his accession, he acted for himself; but his minister of finance was an Italian, Leopoldo de Gregorio, marqués de Squillace, his ideas were those of the French encyclo-

paedists and his attempt to reform the Spanish way of life from the bottom up, as in dress, led to an initial period of friction culminating in the Esquilache revolt of 1766, which caused Charles to fly in alarm from his capital and put an end to the long succession of foreigners at the helm of state.

The count of Aranda (q.v.), who now emerged, with the count of Florida Blanca (q.v.), as the statesman of the reign, had likewise imbibed advanced ideas, particularly as regards the church, in long residence abroad. In April 1767 Charles decreed the expulsion of the Jesuits, as a body not owning allegiance to the state, from Spain and the American colonies and exerted his whole influence to secure the suppression of their society One consequence was the nationalizing and secularizing of education. The Holy Office, firmly denied the right of trial in civil offenses, was finally shorn of its importance. In 1780 it burned its last victim, accused of witchcraft, in Seville. A decree of 1773 proclaiming the dignity of labour, even for the nobility, illumined another facet of the national resurgence. Land distribution to peasants, the colonization of deserted areas (6,000 Bayarians were settled in the Sierra Morena), the spread of new industries under foreign instruction, the creation of a network of canals and highways throughout the country, were among the many measures which, combined with continuous administrative reform, improved the lot of the working classes and stimulated all in the common effort. The new national lottery proved a valuable and popular source of revenue. By 1788 the population had reached 10,250,000.

Charles's foreign policy was rooted in a deep distrust of England, the "enemy" both in America and in respect of Gibraltar and Minorca. Hence the third "family compact" (1761-62) and, since England and France were then at grips in the Seven Years' War, the former's declaration of war on Spain in Jan. 1762. The peace of 1763 cost Spain Florida, all its territories east of the Mississippi and more valuable trading concessions. In 1770 the conflict threatened a renewal over Spain's occupation of the Falkland Islands, from which the defection of France caused it to withdraw. England's dispute with its North American colonies confronted Charles with his most acute dilemma. To aid the rebels was tempting; the implications for his own American colonies of such countenancing of revolt only too obvious. In 1779 he opted to aid, following France's example of two years earlier; and in the general settlement of 1783 he recovered Florida and Minorca. Gibraltar, twice besieged, proved impregnable. Substantial administrative advances in the new world too (among the most beneficial was the institution of imperial free trade) were hampered by the overriding demands of the treasury at home. The years 1780-81 in particular were marked by serious uprisings both of Indians and of Creoles. In the Mediterranean an unsuccessful attempt was made in 1775 to seize Algiers, a notorious centre of piracy. The suppression of corsair raids on the Spanish coast was at length achieved by treaty with the regency of Algiers in 1786.

Charles IV (1788-1808) .- The fourth Bourbon was at the opposite pole in character and gifts from his father. Sluggish and stupid to the verge of imbecility and much influenced by his wife. Maria Louisa of Parma, a coarse, passionate and narrow-minded woman, he soon became the plaything of events. The French Revolution not only meant the end of the "family compact" on which Spain had relied in its policy of opposition to Great Britain, it involved Spain in a crusade on behalf of Louis XVI and, after his execution in Jan. 1793, in enthusiastic support for the first coalition against France. By then Florida Blanca and Aranda had been replaced by a young guardsman, Manuel de Godoy, who was at once the queen's lover and the favourite of the king. paign, undertaken mainly in the Roussillon, was a failure, and French troops advanced into Spain almost to the Ebro. Constrained to make peace by the treaty of Basle (1795)—whence Godoy's title of "prince of the peace"—Spain found itself tied hand and foot to the French republic. The treaty of San Ildefonso (1796) was a virtual renewal of the "family compact," but with terms far more disadvantageous to Spain. A scheme for a joint attack on the English coast was foiled by the battle of St. Vincent, in which John Jervis and Horatio Nelson forced the Spanish fleet to retire to Cadiz. Great Britain further seized Trinidad and set itself to encourage discontent in the Spanish colonies

The French occupation of Rome and the overthrow of the papal government in favour of a republic were offensive to Spanish opinion, as the dispossession of Ferdinand, duke of Parma, of his territories was to the crown, and Godoy fell from office in March 1798. But Spain was not free to pursue an independent policy, and the return of Bonaparte from Egypt and his emergence as first consul began a period of ever-deepening humiliation. Turning his attention to the peninsula, Napoleon fastened on Godoy as his totol, and a new treaty of San Ildefonso (Oct. 1, 1800-), in which Spain ceded Louisiana and six warships against promises concerning the duke of Parma, was followed by Godoy's return to power. In 1801 he led in person an attack on Portugal, at France's behest The invasion was barely resisted, and Portugal undertook to close its ports to England in return for respect for its territorial integrity.

Napoleon, soon involved in a new war with England, extorted from Spain a new treaty (Oct. 9, 1803) more burdensome still than that of 1796, Spain undertaking to pay a monthly subsidy of 6,000,000 fr. and to enforce Portuguese neutrality. Inevitably Spain too was drawn into the conflict with England: the last remnants of its maritime power were shattered at Cape Finisterre and Trafalgar, and an English force seized Buenos Aires.

Spanish subservience to France was increased and the fate of the Spanish crown deeply compromised by a rivalry for power a court between Godoy and the heir to the throne, Prince Ferdinand, whom Godoy discovered to be intriguing secretly with Napoleon for support. By the convention of Fontainebleau (Oct. 27, 1807) Spain had agreed with Napoleon on plans for the conquest and dismemberment of Portugal, thus giving Napoleon an excuse to send a French army under Andache Junot through Spain to Lisbon, whereupon the Portuguese royal family fled to Brazil. When, shortly after, Godoy induced Charles to order the prince's arrest on charges of plotting to dethrone his father and to murder his mother and Godoy, the resultant scandal and confusion enabled Napoleon to pour more and more troops into Spain, under pretext of reinforcing Junot. Soon even this excuse was dropped, and by Feb. 1808 the French invasion stood clearly revealed as one of concuses.

Godov now would have fought but, the king refusing, could only counsel instead that the Spanish royal family too should embark for America. It removed to Aranjuez, where a mob instigated by the prince's party provoked a riot and clamoured for Godoy's head. The rioters were only appeased by Charles's announcement (March 17) of his abdication in favour of Ferdinand. Six days later Joachim Murat occupied Madrid. Napoleon meanwhile had advanced to Bayonne, near the frontier, whither at his orders Murat now dispatched Charles, his wife and Godoy. Napoleon had already decided to place one of his brothers on the Spanish throne and by specious promises easily lured Ferdinand likewise to Bayonne. There, confronted by his parents and Godoy in a scene of pitiful degradation, he was forced to restore the throne to his father, who laid it at the feet of Napoleon. The next six years Ferdinand spent under military guard at Valençay; his parents retired to Rome. On May 13 Murat announced to an improvised "junta of regency" at Madrid that Napoleon desired them to accept Joseph Bonaparte as their king

The War of Independence (1808-14).—Spanish sentiments of loyalty and independence were, however, too profound to be daunted. For the first time Napoleon found himself faced, not by selfish and terrified rulers, but by an infuriated people who rose against the French on May 2, 1808. The rising in Madrid began the movement which ultimately proved fatal to Napoleon's power. At first he treated the novel phenomenon with contempt; but, although Madrid was held by the French, the Spaniards showed great capacity for guerrilla warfare in the provinces. The French were repulsed from Valencia and Pierre Antoine Dupont, who had advanced into the heart of Andalusia, was compelled to retreat and ultimately to capitulate with all his army at Bailén (July 10). The Spaniards now advanced upon the capital, which Joseph Bonaparte had just entered, and expelled him.

To some extent this too was a civil war, for a small but not

unimportant section of Spaniards, who had been much influenced by the doctrines of the French Revolution, continued to see in France the bulwark of liberal principles and looked to Joseph and his constitution of Bayonne as marking the dawn of responsible government in Spain. The struggle for independence, though in a progressive minority, was to seem in retrospect to have been a struggle no less against the spirit of the age. But the combined defection of the crown, of its senior statesmen, of a large part of the higher nobility and of the intellectual Afrancesados made the reaction of the Spanish people, thus left leaderless, the more remarkable. Its first concern was to improvise a provisional organization based on earlier provincial and regional juntas; and bourgeoisie and provincial yeomanry together succeeded in creating a system capable of resisting French domination.

The military superiority of the French ruled out hopes of an immediate victory, but Napoleon himself was compelled to come to Spain to direct operations. With this the tide swept once more against the patriots. Napoleon restored his brother in Madrid. Sir John Moore, advancing from Portugal with an English army to the relief of the capital, was forced to retreat; and only after a desperate battle, in which he fell, could his troops re-embark at Corunna. Napoleon, thinking his task completed, had now withdrawn, leaving Marshals Nicolas de Dieu Soult and Claude Victor-Perrin to complete the reduction of the provinces. The two defenses of Saragossa under siege (1808 and 1809) and that of Gerona (1809) are among the most heroic pages in the annals of Spain, but proved alike unavailing. With the fall of Seville in Jan. 1810 the central junta fled to Cádiz. Only the obstinate resistance of the duke of Wellington in Portugal, the continuous activity of the guerrilleros and dissensions among the French saved the peninsula from final submission.

The Spanish Cortes, if never so entirely suspended as the statesgeneral of France, had become in the course of the 18th century little more than a rubber stamp. Already under Philip V those of the other regions had been merged in the Cortes of Castile. Now, under the influence of the ideas of revolutionary France, the reformist patriots of Cádiz planned their re-establishment on a more democratic though still national basis, and in 1810 a new Cortes was convened in that city. It included for the first time delegates of the colonies, chosen perforce, like those of enemyoccupied Spain, from among those of their citizens who happened to be then present in Cádiz. The third estate, with 184 deputies, was sufficient to swamp the nobles and the clergy, and the debate on the new constitution soon produced a deep cleavage between Liberales-it was then that the term took on its party political connotation-and Serviles. The former won the day, and the constitution of 1812 was duly promulgated. Its 384 articles attributed to the Spanish nation the exclusive right to determine its fundamental laws. The king would legislate with the Cortes, a single chamber; but royal decrees, to be valid, required the countersignature of a minister, and ministers were responsible to the Cortes. Freedom of the press, though not of religious belief, was assured, and legal codes were made uniform for the whole country. The constitution was doubtless unworkable in many respects and never achieved more than a symbolic importance; but by vesting in the people for the first time the responsibility for determining under what laws they should live it closed an epoch in their history and made of constitutionalism the first characteristic of the new age. Its influence was profound also in two other directions. Its radical idealism, offending the mass of the people, threw them into the arms of the liberated Ferdinand and prepared the way for one of the most reactionary regimes in Spain's record, the tendency persisting thereafter for Spanish politics to swing from extreme to extreme. Also it gave warrant for the later identification of liberalism with anticlericalism on the one hand and with centralization on the other, to the great complication and confounding of the political scene in subsequent periods of stress and crisis.

Expulsion of the French.—In the eventual recovery of its territorial integrity and independence, Spain owed a great deal to British assistance. Wellington's campaign of 1812, though it gave

him the temporary occupation of Madrid, was again indecisive; but, after Napoleon's disastrous retreat from Moscow and the withdrawal of French troops from Spain to central Europe, he found himself in 1813 fighting at last on equal terms. The defeat of Jean Baptiste Jourdan at Vitoria on June 21 finally decided the issue in the peninsula. Joseph retired altogether, and Wellington fought his way across the Pyrenees into France. Napoleon, after his crushing defeat at Leipzig, recognized the impossibility of retaining his hold on Spain by releasing Ferdinand, who returned to Madrid in March 1814.

Ferdinand VII (1814-33).—Before entering Spain Ferdinand had undertaken to maintain the constitution of 1812; and on reaching Figueras he was met by a formal demand in this sense from the Cortes. But he was quick to appraise the true temper of the nation and in rejecting the demand now he was supported alike by the army, the church and the masses. Had he been capable of governing well, he might have ruled despotically for long enough. He was instead base by nature, without real capacity and at once cruel and cowardly. Himself governed by a camarilla of low favourites, he changed his ministers incessantly on caprice and was consistent only in his ferocious persecution of the Liberales.

Partial revolts were easily crushed. That of Jan. 1820, beginning as a mutiny at Cádiz in protest against the sending of an expeditionary force to crush rebellion in the American colonies, became a revolution Its leader and hero, Col. Rafael Riego, was one of a number of officers, many of them erstwhile prisoners in France, who now subscribed to liberal doctrines. Six years of tyrannical excesses had turned the army largely against Ferdinand, and for three years, till 1823, he was a prisoner in the hands of a section of his subjects, who proclaimed once more the constitution of 1812. Ferdinand appealed for help to the monarchies of the Holy alliance, who were much concerned to see kingship thus contemned. As early as 1820 the emperor Alexander I of Russia had proposed joint intervention. The project came to nothing because of British opposition and the refusal of Metternich to contemplate the march of a powerful Russian force through the Austrian dominions. In 1822 the question arose again at the congress of Verona, France proposing that it march into Spain, as Austria had into Naples.

Great Britain saw in the demand only a pretext for reviving traditional Bourbon ambitions in the peninsula and protested vigorously; but the mandate was granted by a majority of the powers and on April 7, 1823, Louis Antoine de Bourbon, duke of Angoulême, crossed the Bidassoa at the head of a powerful army. The result was a startling proof of the flimsy hold of liberalism on the Spanish people. What Napoleon had failed to accomplish in years, Angoulême seemed to have achieved in a few weeks. Napoleon, however, had sought to impose upon Spain an alien dynasty; Angoulême came to restore the Spanish king "to his own" and found some Spaniards forthcoming with active support and the majority at least tacitly co-operative. The Cortes, carrying the king a prisoner, fled again to Cádiz, where after a brief siege it surrendered. Ferdinand, alleging compulsion, refused to honour the amnesty he had sworn, and the French troops witnessed with helpless indignation an orgy of cruel reaction begun under the protection of their bayonets.

The Spanish Colonies .- The emancipation of Spain's American colonies was an indirect result of Napoleon's detention of Ferdinand and invasion of Spain. Juntas in the various administrative capitals overseas assumed power first in the name of Ferdinand against Joseph Bonaparte, then in the name of the colonies themselves against Spain. Some of these had already become independent de facto by 1810, and many more became so in the ten years following; and the recognition of their independence de jure was, for Great Britain at least, merely a question of time. When the French invasion of Spain was seen to be inevitable, George Canning informed the French government that Great Britain would not tolerate any subjugation of the Spanish colonies by foreign force. The United States, though declining to act in concert, followed with the famous message of Pres. James Monroe (Dec. 2, 1823) intimating his country's opposition to any interference by Europe in the Americas. The republic of Colombia had

already been recognized by the United States in 1822. Great Brit-old, was declared of age. ain recognized Mexico and Colombia in 1824 and only delayed recognition of the other new states until they should have given proof of stability. There now remained to Spain, of its far-flung empire, only the islands of Cuba, Puerto Rico and the Philippines.

The Succession Question .- Ferdinand, still childless on the death of his third wife in 1829, married Maria Cristina of Naples in that year and in so doing threatened the mounting hopes of his brother Don Carlos regarding the succession. Don Carlos was likewise an extreme reactionary, and the clash of ambitions threw Maria Cristina on the support of the Liberals. The birth of a daughter, Isabella, in 1830 greatly complicated the issue. By the ancient law of Castile and León women could rule in their own right. This right had, however, been abrogated by an act of 1713 designed to prevent any union of the crowns of Spain and France; and, although Charles IV had restored the former position in 1789, his enactment had never been published and its validity was now hotly disputed. Hence the birth of Carlism, which was for more than half a century to be a disturbing factor in the Spanish scene. When, on Sept. 29, 1833, Ferdinand died, his daughter was proclaimed queen as Isabella II, with Maria Cristina as regent. The First Carlist War broke out almost immediately.

The Regency for Isabella II (1833-43) .- Maria Cristina too would have ruled despotically if she could, but the support of the army and control of the machinery of government were not in themselves sufficient to resist the Carlists, in whose ranks were to be found not merely the clergy and other ultraconservative elements but also large numbers of Basques, Catalans and other peoples of the periphery who had been persuaded that their regional fueros were in danger and supplied the real fighting strength of the movement in defense of them. The necessities of her position thus drove the regent to accept parliamentary institutions under the constitution of 1837 and the return from England and France of the many exiles of the preceding decade gave much support to the liberal cause. But neither Maria Cristina nor her daughter ever genuinely accepted the principle of representative government and there ensued, within the civil war, a bitter struggle between parliament and the parliamentary cause on the one hand and the crown on the other, to the discredit of both.

The First Carlist War, which was for the crown a dynastic issue and for the nation a conflict between irreconcilable political principles, involved Great Britain in military commitments on the government's side and threatened more than once to disturb the peace of Europe. It ended with the convention of Vergara of Aug. 31, 1830, a recognition of Carlist defeat. Baldomero Espartero, the Liberal general, undertook to recommend to the Cortes the substantial confirmation of the Basque fueros, and Don Carlos left the country. But the Carlist cause remained alive; and the Cortes, which insisted, in the name of national unity and uniformity, on whittling down the fueros until little more than administrative autonomy remained, ensured continuing Basque support for Carlism. An earlier measure of kindred intent had been the supersession for administrative purposes, in 1833, of the earlier kingdoms of Spain by 49 provinces on the French model. From that year dates too the Catalan renaixença, a resurgence of regional feeling at once cultural and political that was to have far-reaching consequences. Another enactment destined to provoke repercussions for many years was the acceptance in the constitution of 1837 of state responsibility for the upkeep of the church and the consequent disposal by the state of ecclesiastical property. The Jesuits, readmitted by Ferdinand VII, had been re-expelled in 1835.

With the removal of the Carlist threat to the throne the regent was emboldened in her absolutist leanings. The new constitution of 1837, though much strengthening the royal prerogative, was still liberal and bore traces of the English Reform bill of 1832. Maria Cristina now sought to have it overthrown. Failing in this, she directed an attack on the independence of the municipalities in 1840, which provoked a major crisis that culminated in her abdication. Espartero was proclaimed in her place, and Spain had its first experience of the army in political control. After three disturbed years a military rising, with liberal and moderate backing, drove Espartero likewise into exile, and Isabella, then only 13 years

Isabella II (1843-68) .- The new reign proved but a continuation of the regency, a confused conflict between the attempts of the crown to rule despotically with a mere pretence of a Cortes and the nation's growing demand for honest and efficient parliamentary government. New constitutions (1845, 1852, 1855) alternated between the progressive and the reactionary and caused a spurious importance to attach to the letter as distinct from the spirit of constitutionalism. Party leaders were almost always generals, Espartero, Ramón María Narváez (leader of the "Moderates" or extreme conservatives), Leopoldo O'Donnell, Juan Prim. As such they were unable, even where willing, to further the cause of civic responsibility in the nation at large.

The queen's marriage in 1846 provoked international repercussions. Louis Philippe of France, seeking to revive the family alliance, with the aid of the queen mother constrained Isabella to wed her cousin Don Francisco de Asís de Borbón, who was believed to be impotent; on the same day her younger sister Maria Luisa Fernanda was married to Louis Philippe's son Antoine, duc de Montpensier. The affair broke the entente between England and France-Palmerston having only agreed on condition that the second marriage waited on the birth of an heir to the first-and was a contributory cause of the downfall of Louis Philippe (see FRANCE: History). The church's right to hold and acquire property, restored by a concordat of 1851, was again called in question by the pope's acquiescence, under a new agreement of 1858, in the policy of dispossession. The major external event of the reign was the Moroccan War of 1859-60, in which victory over the Moors in the field was foiled of its full harvest by the opposition of England and France.

Cumulative discontents against the crown, reflected in the emergence of a republican party in 1854, culminated in a mutiny at Cádiz, in Sept. 1868, of a squadron under Adm. Juan Bautista Topete, which became the signal for a general secession. The stand for the queen made at Alcolea by Gen. Manuel Pavía, marqués de Novaliches, was an exception. Even her prime minister, Luis González Bravo, deserted her. Isabella crossed into France an exile, and her reign ended. The revolution of 1868 was the first to be openly directed against the dynasty. The "spurious race of Bourbon," it was boasted, had disappeared; and, as in 1810, sovereignty was again for the moment vested in the people.

## AMEDEO AND THE FIRST REPUBLIC, 1870-75

The mass of the nation was, however, not yet ready for a republic, and a constituent Cortes, assembled in 1869, voted for a continuance of the monarchy under a different monarch; Gen, Francisco Serrano, a leader of the revolution, was declared regent until one could be found. In the constitution of 1869 may be found, for the first time since that of 1812, the entire program of the liberalism of the period. Monarchist opinion was divided, some favouring Isabella's son Alphonso under a regency, some the widower Ferdinand of Saxe-Coburg (formerly king-consort and then regent of Portugal), others the duc de Montpensier, or a Carlist or even the aged Espartero. The search for a democratic king, said Prim, the prime minister, was like looking for an atheist The offer of the crown to Prince Leopold of in heaven. Hohenzollern-Sigmaringen proved the spark that fired the Franco-

At length, in Aug. 1870, Prince Amedeo (in Spanish, Amadeo) of Savoy, second son of Victor Emmanuel II, accepted the offer of nomination. He was elected on Nov. 3 and landed in Cartagena on Dec. 27. On that day Prim was assassinated. Amedeo's reign lasted nominally till Feb. 1873. It was a period of turmoil and confusion. The monarch, become the tool of intriguing politicians, was looked on as an intruder by men of principle, royalist and republican alike. The Carlists threatened a new rising in the north, there was republican agitation in the towns and when the first honourable excuse presented itself Amedeo resigned.

Republican Interlude.—Disillusionment with monarchy was for the moment complete, and the Cortes proclaimed Spain a republic. New elections were held to a constituent Cortes, but the republic ran its brief and tempestuous course without a constitu-

tion. Beyond initial acceptance of the federal idea there was little agreement on first principles. Four presidents held office within the year, Estanislao Figueras, Francisco Pi Margall, Nicolás Salmerón and Emilio Castelar y Ripoll; ministries never knew stability, and many regions disavowed the authority of Madrid and proceeded to act independently. Cantonalists, going beyond federalism to a proposal to split Spain into cantons, seized Cartagena and the Spanish navy in its harbour, which was recovered for the government only by the help of British and German squadrons. The republic had further to contend with a new Carlist revolt, with monarchist opposition and with an insurrection in Cuba.

As it grew ever clearer that only the army could restore authority and order, one major plank in the republican program, the taking of the army out of politics, had perforce to be abandoned, and General Pavía was charged with the pacification of Andalusia. Castelar, reintroducing conscription, provided the means of reducing Cartagena and pursuing the war against the Carlists with vigour. When the Cortes reassembled in Jan. 1874 the extreme parties voted against Castelar, whereupon Pavía, then captain general of Madrid, turned the Cortes into the streets. The federal republic was dead. A unitary regime followed, under General Serrano, until, in Dec. 1874, another army pronunciamiento restored the Bourbons. Alphonso XII, 17 years old and till then at school in England, landed at Barcelona on Jan. 10, 1875.

## THE LATER BOURBONS, 1875-1931

Alphonso XII (1875–85).—National exhaustion and disillusion caused a substantial rallying of the nation around the young king. Pacification, military and political, was his first concern. The Carlists were not finally quelled until the beginning of 1876, when a general amnesty was balanced by the forfeiture by the Basque provinces of their differential system of 'taxation and military service. Part of the large army thus released was then sent to Cuba, where after a further 18 months of fighting the insurgents accepted the conventign of El Zanjón (Feb. 12, 1878). Arsenio Martínez de Campos, Spanish commander in chief, was made governor general and held out to the island the prospect of reforms, including a more liberal tariff and eventual self-government.

Alphonso's first premier, the conservative Antonio Cánovas del Castillo, ruled at first dictatorially without the assistance of parliament. Royal decrees set aside most of the legislation and reforms of the previous regime, respecting only—for a term—universal suffrage, on which basis a new Cortes was convoked in 1876. The constitution of that year was a compromise between that of 1845 and the more democratic principles of the charter of 1869; it was to remain in force for 47 years. By it the franchise was limited to taxpayers; the senate became in part elective; religious dissidence was tolerated though not recognized; and a considerable freedom of association was granted. Constitutional guarantees might, however, be suspended when the security of the state so demanded, a provision that left a tempting reserve of power in the hands of the crown, while the parallelism of civil and military districts facilitated its invocation.

The Liberals under Práxedes Mateo Sagasta formed the Fusionista party, whose name was indicative of its heterogeneity. But the real opposition came from the Socialist-Republican left. From the founding in 1869 of a Spanish section of the international, labour organization developed rapidly. The split between Marx and Mikhail Bakunin was reflected in Spain on a regional basis, labour being predominantly Marxist in Castile and Anarchist in Catalonia. Regionalism, likewise at its most active in Catalonia, provided another outlet for political dissatisfaction with Madrid.

Cánovas' first administration lasted till Feb. 1881, when, under suspicion of heading the country once again toward absolutism, he gave way to Sagasta and the Liberals. Thereafter, to the end of the century, the two parties alternated in power on an agreed rotatory system based on "made" elections that soon became one factor in the gradual discrediting of the restored monarchy. In Aug. 1883 an attempted republican rising, though soon quelled, led to the discovery of widespread revolutionary activities throughout the country. Fifty Republicans were returned to the Cortes at the general election of March 1893. In the country at large the

last two decades of the 19th century were scarred by an increasing resort to direct action and crimes of violence, with corresponding waves of harsh official repression.

Alphonso's first wife, his cousin Mercedes, daughter of the duc de Montpensier, had died in May 1878, five months after the wedding. His second marriage (1879) was with Christina (Maria Cristina), a second cousin of the Austrian emperor Francis Joseph. On Nov. 25, 1885, he died, leaving two daughters. Six months later a posthumous son, Alphonso XIII, was born. The queen was proclaimed regent.

Regency for Alphonso XIII.—The regency began with five years of Liberal rule, marked by the civil code of 1889, another major step in the consolidation of the country's still heterogeneous legislation, by the restoration of universal suffrage and of trial by jury and by a liberalizing of the laws affecting the right of association and the liberty of the press. Attempts to curb the political proclivities of the army were less successful and added military to Conservative opposition. The elections of 1890, which returned the Conservatives to office, showed that very few of those lately enfranchised had voted; they showed also that the home office's

control of the voting continued as before.

Cánovas now based his economic policy on protection, completely reversing the moderate free-trade policy which had been so beneficial to Spanish foreign trade since 1868. Heavy increases in duties on agricultural imports, particularly on breadstuffs, and the denunciation of all treaties of commerce that contained most-favoured-nation clauses soon made their adverse effects felt and evoked loud protest. Industrial interests alone benefited, and imports of raw materials, notably chemicals, coal and coke, increased. In 1892 Cánovas admitted that never since the restoration had the budget been balanced and that the exchequer was bankrupt. Political bankruptcy could be seen further in the failure of both parties to tackle the problem of the latifundios and a land-sterved peasantry. Signs of labour unrest multiplied, again chiefly in Catalonia.

Morocco and Cuba.—The Rif tribes bordering the Spanish zone in Morocco had never been good neighbours. In 1894 an incursion into Spanish territory resulted in defeat for the Spanish forces and a severe shock to public opinion at home. An army of 25,000 men, with 30 generals, was sent to Mellila, but hostilities were averted for the time being by a treaty signed in Fez and by the sultan's agreement to pay an indemnity of 20,000,000 pesetas. Earlier, between 1884 and 1886, Spain had established dominion over the vast territory of Rio de Oro, south of Morocco, in furtherance of a new African policy of pacific penetration advocated by Joaquin Costa.

The position in Cuba had again grown threatening, and press censorship left Spanish opinion unprepared for its outcome. Cuban autonomist deputies in the Cortes had formally tabled the demand for home rule in 1878, but this was rejected, as was a Conservative measure of 1893 for political and administrative reforms tending in that direction. In 1895 a much weaker Cuban Reform bill was passed by all parties, but before it could be promulgated a separatist rising had broken out in the old haunts of Creole dissatisfaction, near Santiago de Cuba, backed by a strong body of sympathy in the United States. Sagasta dispatched a force of 12,000 men to reinforce the 15,000 Spanish troops already in the island, and Cánovas, succeeding once more to the premiership, insisted that submission must precede any concessions. Gen. V. Weyler y Nicolau applied himself to the stamping out of disaffection with a ruthlessness which brought repeated diplomatic representations from the United States, which at the same time was supplying the rebels with arms,

Realizing the danger of more direct U.S. intervention, Cánovas presented to the Cortes a bill granting Cuba a substantially enlarged autonomy. His assassination by an anarchist on Aug. 9, 1897, brought Sagasta back into office. Recalling Weyler, Sagasta hastily enacted conciliatory legislation and sought to propitiate the United States, even offering a treaty of commerce which would have allowed the U.S. every advantage in trade with the West Indies possessed by Spain itself. But things had already gone too far, both in Cuba and in the United States, where public opinion

I32 SPAIN

pressed irresistibly on congress and president alike.

Spanish-American War, 1898.—On Feb. 15, 1898, in circumstances never clearly established, the U.S. cruiser "Maine" blew up in the port of Havana, and events moved quickly to a crisis. Spain appealed to courts and governments and to the pope for mediation, but none was disposed to go beyond mild representations to Washington. In April Pres. William McKinley approved a resolution demanding the cessation of hostilities in Cuba with a view to evacuation by the Spanish forces. Sagasta gave the U.S. minister in Madrid his passports and severed relations with the United States; the known inadequacy of Spain's resources for a struggle could not prevent it from yielding to the urge to defend the last remnants of its colonial empire.

The sequel is soon told. The Spanish fleet in the far east was defeated in Manila bay, the Caribbean fleet was destroyed off Santiago de Cuba and all communication between Spain and the colonies was severed. Within a fortnight of the landing of a U.S. force near Santiago the Spanish garrison surrendered (see SPANISH-AMERICAN WAR). At the end of July Spain sued for peace. The agreement of Aug. 9 stipulated clearly that Spanish rule in the new world must be considered at an end; and by the peace treaty of Paris (Dec. 12, 1898) Spain renounced unconditionally all sovereign rights over Cuba and Puerto Rico and ceded to the United States, in consideration of a payment of \$20,000,000, the Philippine Islands, the Sulus and the largest of the Marianas. The Carolines and a few other Pacific islands Spain sold to Germany in 1899, and a couple of islands omitted in the treaty of Paris were purchased by the United States in 1900. Apart from holdings in North and West Africa, the Spanish empire was at an end.

The Reaction in Spain.—The Liberal goverment was held responsible for the debacle; but the seeds had been sown long before, and the change to a Conservative cabinet was the least significant among its consequences. From the mood of sober analysis and heart-searching that ensued there emerged the "generation of '98", a group of thinkers who through their chosen medium—the essay—effected a renovation not merely of literature but of the country's intellectual life. The debate on the country's role in history led to a cleavage between europeizantes and africanizantes; it led also to a new interest in Africa as the one remaining field of overseas activity. With the radical reduction of its commitments the army became top-heavy, at once an intolerable drain on the nation's economy and more prone than ever to meddling in politics. The wave of solidarity with Spain that swept through Latin America went far to neutralize remaining antagonisms in this sphere.

Long-due reforms in taxation and the servicing of the nation's debts were carried through by a vigorous Conservative minister of finance, Raimundo Fernández de Villaverde. Bondholders were called on for even heavier sacrifices than taxpayers, and the interest on colonial debts, like that on internal debts and on Spanish holdings of external debts, was made payable in pesetas. But in the main the political scene remained untouched by the new spirit. Sagasta, premier once more in March 1901, was confronted by two major problems. One was the growth of the religious orders and congregations, in defiance of the Law of Associations of 1887 by which all congregations were required to register their members and, when not specifically recognized under the concordat of 1851, to apply for authorization. A proposal now to enforce the law greatly incensed the church. The papal nuncio announced that Rome would only consent to discuss the question on condition that all requests for authorization would be granted. To avoid a crisis just when the young king was about to become of age, Sagasta accepted a modus vivendi. A final settlement was not reached with the Vatican until 1912,

Industrial unrest constituted a more pressing peril. Fomented by socialist agitation and by anarchist direct action, it led in Jan, 1902 to serious riots in Barcelona and Saragossa and on Feb. 16 to a general strike in the former city. General Weyler's methods in restoring order all but brought the government down. They provided no solution to anarchism, which under the influence of Georges Sorel was now moving toward syndicalism as a basis for organized opposition to all government as such.

Accession of Alphonso XIII, 1902.—Alphonso XIII was enthroned on his 16th bitthday, May 17, 1902. He was still then under clerical and reactionary influences, and his contemptuous treatment of ministers showed from the beginning an intention of intervening actively in politics. His first official act was to countermand a decree closing the military colleges, aimed at reducing the disproportionate officer strength of the army. Sagasta died in 1903. Conservatives and Liberals alike were now suffering from weakened leadership, and there ensued a period of instability and frequent changes of government.

A tendency to disintegration in the political parties was symptomatic of the growing subordination of national to sectional interests. It became an important factor in the eventual collapse of representative government. This political instability contributed to the general unrest; and the old antagonisms, born of the conflict between the industrial north and the agricultural south and of the now traditional cleavages over regional, social and religious issues, were increasingly complicated by labour agitation. The notorious Law of Jurisdictions of 1905, under which attacks on officers and military institutions were to be tried before military tribunals, was a serious capitulation of the civil authority, that had farreaching consequences.

Alphonso's marriage on May 31, 1906, to Victoria Eugenia (Ena) of Battenberg, princess of Great Britain, marked a stage in his emancipation from clerical-conservative tutelage. Ecclesiastical controversy again loomed large at this period, formal recognition of the validity of civil marriage arousing such agitation among the clergy that the government threatened the bishop of Tuy and the Cordova chapter with prosecution. A new Law of Associations in 1906 brought the Liberal party itself to the verge of disruption, and after three changes of premiers the Conservatives returned to power under Antonio Maura.

Maura (1907-09).—Maura, who had already been premier under the regency, had many qualities of leadership. A sincere Catholic, though no clerical, he pursued first the maintenance of order and the reform of local government. A bill to the latter end was submitted to the Cortes in Oct. 1907. Aimed at destroying the power of the caciques or local bosses and at educating the electorate in their privileges and responsibilities, it made voting compulsory, abolished official interference with the polls and increased considerably the responsibility of local elected bodies. The bill met with strong Liberal opposition because of its alleged regionalistic tendencies and, though finally approved by the lower house in Feb. 1909, did not reach the statute book.

The elections of 1907 were notable for the return of a strong republican minority and the striking victory of the Solidaridad Catalana, a fusion, resulting directly from the Law of Jurisdictions, of seven Catalan parties in defense of regionalist interests. Of the 44 seats allotted to Catalonia, 41 were gained by its candidates. Maura, ruling rather as an enlightened despot than as the head of a constitutional government, was concerned also to strengthen the navy, to reform and to reconstruct the police force, to institute industrial tribunals and to regulate the conditions of work of women and children.

Trouble long brewing in Morocco broke out in July 1909 with an attack by Rif tribesmen on Spanish railway workers. The need to reinforce the Spanish troops in Africa had for some time been apparent, but Maura had hesitated to lay the necessary estimates before the Cortes. The proposal now of the war minister, Gen. Arsenio Linares, to organize a new field force by calling out the reserves, with its vivid memories of the useless miseries of earlier overseas expeditions, provoked another general strike in Barcelona; and a movement at first directed against "conscription" rapidly developed into a revolutionary attack on the established order in church and state that spread to the whole province. Churches and convents were favourite targets for violence. In Barcelona the rising was suppressed after three days of street fighting (July 27–29).

On July 28 martial law was proclaimed throughout Spain, and a military reign of terror continued until the end of September. In the fortress of Montjuich in Barcelona were collected not only rioters caught red-handed but many others, notably journalists,

whose opinions were unpalatable to the government. A sensation was caused by the arrest of Francisco Ferrer, a theoretical anarchist well known in many countries for his anticlerical educational work and especially as the founder of lay schools in Spain. Ferrer was tried by court-martial and shot. The execution aroused widespread indignation throughout Europe and produced a ministerial crisis in Madrid. The government, already weakened by a reverse in Morocco (Sept. 30), was furiously attacked by the Liberals under Segismundo Moret y Prendergast at the opening of the Cortes in October, and Maura resigned.

Moret and Canalejas (1909-12).-Moret's Liberal ministry sent General Weyler back to Barcelona to keep order, released most of the Montjuich prisoners, reduced the forces in Morocco and reopened negotiations with Rome for a modification of the concordat. In Feb. 1910 Moret was forced to resign through the king's refusal to grant him a dissolution, and José Canalejas y Méndez, the outstanding Liberal of his day, took office. His government, "inspired by the universal spirit of liberty of conscience," tackled the continuing refusal of the religious houses to comply with the law (in respect of registration and the payment of taxes when engaged in industry and commerce) and announced measures both to restrict the number of religious houses and to implement the religious toleration enshrined in the constitution. A violent Catholic agitation resulted, 72 Spanish bishops and archbishops presenting a formal protest to the government. To attacks from the Vatican Canalejas retorted with the famous "Padlock law" at the end of 1910 forbidding the settling of further congregations in Spain until a revision of the concordat should have been agreed on with Rome.

On the Vatican's demanding that all the obnoxious measures be rescinded as a preliminary to negotiations, the Spanish ambassador to the Vatican was recalled. Hints were dropped in papal circles of a possible rapprochement with the Carlist claimant to the throne, and diplomatic relations were not restored until 1912. The overthrow of the monarchy in Portugal on Oct. 5, 1910, and the expulsion thence by the new republican regime of all religious congregations did not ease the government's difficulties.

French activities in Morocco at this time compelled Spain to adopt a more active policy in its zone. To counterbalance the French entry into Fez a Spanish force was landed at Larache in June 1911 and took Alcazarquivir and Arcila. The recruiting of native regiments under Spanish officers did something to lessen popular indignation at home. France was prevented by the Agadir incident from reacting strongly, but a certain tension continued and pervaded the negotiations for a Franco-Spanish agreement following on the Franco-German treaty on Morocco. Concluded on Nov. 27, 1912, that agreement reduced the Spanish zone for the third time in 12 years.

A general railway strike in the middle of 1912 threatened the country with chaos. Canalejas met it by drafting railway workers into military service and compelling them to continue at their posts as soldiers. Such firmness was balanced by a genuine readiness to understand legitimate grievances, which led the Catalanists to make a serious attempt to come to terms. The premier responded by introducing a bill of mancomunidades (common-bine in one joint body (mancomunitat) to which the state would grant a substantial measure of devolution. The bill, which was inevitably unacceptable to many Liberals and Conservatives alike, and was regarded in Catalonia as merely a first instalment of Catalan demands, had not passed the Cortes when, on Nov. 12, 1912, Canalejas too was assassinated by an anarchist.

The Parties in Decline.—The new premier, Alvaro de Figueroa y Torres, conde de Romanones, was natural heir to the Liberal leadership, but he was unable to maintain the firm party discipline of his predecessor. He pursued meantime Canalejas' policy of seeking to attract and absorb the more moderate wing of the republican left, a policy the desirability of which had been greatly enhanced by the revolution in Portugal. Alphonso himself recognized the need for such an accommodation, and the response of republican leaders like Melquiades Alvarez led to hopes that the disintegration of the regime might yet be checked.

These hopes were dashed, firstly by an internal crisis in the Liberal party over the bill of mancomunidades, then by the "implacable hostlity" proclaimed by Maura against any policy of collaboration with the antidynastic parties. With the resignation of Romanones in Oct 1913 the king realized that the Liberal policy which he had consistently followed since 1909 was at an end. Maura's views aroused, however, such intense popular resentment that Alphonso entrusted responsibility instead to his fellow-Conservative Eduardo Dato, a choice that initiated the disintegration of the Conservative party in its turn.

The tangled fate of the bill of mancomunidades was resolved, against Dato's judgment, by a royal decree of Dec. 18, 1913, that granted to the four Catalan provinces the right to group together for "exclusively administrative purposes within their competence." This and several similar royal decisions in military matters, which savoured of unconstitutional action, created considerable opposition to the government. But internal difficulties were soon to be merged in the all-absorbing preoccupations and repercussions of World War I.

World War I.—The international situation of Spain at the outbreak of war in 1914 was determined officially by the agreement between Spain, France and England signed at Cartagena in 1907 and confirmed in conversations held there in 1913 between Raymond Poincaré and Romanones, which stipulated that. "should new circumstances arise tending to alter the territorial status quo" in the Mediterranean or on the Atlantic coasts of Europe and Africa, the three powers would "enter into communication" in order to take any necessary measures.

The war was obviously such a circumstance. France and England made no sign, but Dato promptly declared for absolute neutality, Spain having no stake in the conflict. As for the nation, its sympathies were divided. The working classes, most of the intellectuals and the trading communities—the Liberal left—were pro-Ally. The clergy, most of the army and of the bureaucracy and the "idle rich"—the Conservative right—were pro-German. But there was agreement on the one essential of keeping out, and the Cortes, resuming its sittings on Oct. 30, 1914, unanimously endorsed the government's decision.

A debate on military reforms brought Dato's government down in Dec. 1915, and Romanones again formed a Liberal ministry. By then the country was profiting from industrial activity on the Allied account, the peseta appreciated and the foundations were laid for the repatriation of the foreign debt. The picture had its reverse. In Morocco military operations were again necessary, this time to defend the mines from hostile tribes; while Spanish shipping was victimized by a ruthless German submarine campaign. By Sept. 1916 Spain had lost more than 30,000 tons by torpedo attack and another 50,000 in obscure circumstances. When, on Jan. 31, 1917, Germany intimated an "absolute blockade" of the Allied coasts, Romanones delivered a spirited answer intended partly to test public opinion.

His resignation on April 19, which cost him the leadership of his party, was not solely the result of the nation's failure to rise to his Toward the middle of 1916 the army had begun to organize secretly its so-called juntas de defensa in furtherance first of its professional efficiency, second-and soon chiefly-of its traditional prerogatives, the threat to which came principally from the king's fondness for personal intervention. Before long they were presuming to dictate to the government in a manner which led Romanones to attempt their dissolution. But this new menace to authority from the one bulwark of order loomed larger with each endeavour to exorcize it, and Romanones chose the easier path. Under his successor, Manuel García Prieto, an order to arrest the leaders of the juntas provoked an ultimatum (June 1, 1917) that brought the new government down; and Dato, recalled to office, capitulated before them, conceding to their regulations the force of law. This victory of a movement revolutionary in essence encouraged at first, in a public not alive to its implications, hopes of a renovation of political life. Coupled with early reports of the Russian Revolution, it stimulated the ferment at work in the country, and political manifestoes asking for a "renovation" in government and constitution followed one another (Socialists June 12,

Catalanists June 16, left coalition June 16).

In the teeth of government opposition, an assembly of senators and deputies convoked in Baraclona formally demanded constitutional reform and set up three commissions to report to a second meeting in Madrid. This movement, which might conceivably have provided the renovation so urgently needed, was defeated by the resort to direct action of extreme labour elements. On Aug. 13, three days before the planned second meeting, a revolutionary general strike broke out, led this time by the Socialist U.G.T. (General Workers' union) of Madrid and aimed openly at establishing a socialist democratic republic, which soon threatened to paralyze the whole country. A state of war was again declared. The army now showed its true colours and put down the strike by machine guns, and the juntas remained the only real force left in the country.

Among the victims was the constitution. The new minister for war imposed on the king by the juntas, Juan de la Cierva, dominated a heterogeneous ministry of Maurists, Liberals and Catalanists. Its short life (Nov. 1917–Feb. 1918), in spite of army support, showed that a severe blow had been struck not merely at party government but at cabinet government. Brought down by a telegraph stilke, it was followed by a hiatus that only ended when Alphonso, at a midnight meeting of former premiers at the palace on March 21, constituined them under threat of abdication to form a ministry of all the talents, under Maura. This lasted till Nov. 6. The abdication of the kaiser and the toppling of thrones throughment in the return of the Liberals to power, first under García Prieto, then (Dec. 3) under Romanones, whose first act as premier was to visit Pres. Woodrow Wilson in Paris.

The Postwar Situation.-Spared the war, Spain had passed nonetheless through a very disturbed and anxious four years. The submarine war cost it 65 vessels, in all 140,000 tons, which Germany had agreed to indemnify on a ton-for-ton basis. Against this, the influx of capital went far to revolutionize its economy. Gold reserves in the Bank of Spain, £22,680,000 in 1914, had risen to £88,920,000 in 1918. Not merely was Spain able to resorb in large part its foreign industrial debt and, almost entirely, its national debt and to acquire the ownership of the railways, new industries were founded, not all of which disappeared with the return of peace, and in older industries such as the Basque iron and steel works, plant and conditions were modernized. A mingling of two political currents, one a democratic and constitutional agitation born of the Allied victory, the other a revolutionary agitation akin in the civil sphere to that of the juntas de defensa in the military, created an involved situation in Barcelona which issued in the spring of 1919 into open conflict between the military and the civil authorities. When the former expelled the latter from the town, the failure to take up so flagrant a challenge brought the government down, and again there ensued a period of cabinet instability. Its most notable feature was that "made" elections, the mainspring of the old system, were failing now to produce the desired majorities. On March 8, 1921, Dato, who had been engaged in trying to rebuild Conservative unity, was assassinated.

The murder accelerated the final disintegration of the rotatory system which, ever since the death of Alphonso XII, had served the monarchy as substitute for a real constitutional regime on the English model. To its own internal weaknesses was added the triple assault from outside. There were the antidynastic elements, once lumped together under the common label of Republicans, now moving toward socialism on the one hand and toward different varieties of syndicalist or anarchist revolution on the other hand; there were the Catalan home rulers, gradually evolving from autonomy toward separatism under the stimulus of the respect shown by Versailles for the principle of self-determination; and third there was what might be called the military syndicalism embodied in the defense juntas.

With the last-named, governments lacked the moral courage to deal; toward the violence so frequently associated with the first they opposed more violence, failing to recognize legitimate grievances where they existed and tending always to identify the employers' interests with those of authority. To Catalanism opnosi-

tion in Madrid was instinctive, and the failure of a new approach from Barcelona in 1918-19 did much both to strengthen and to unify support for the movement throughout Catalonia. By 1923, when two strong groups, Estat Català and Acció Catalana, of the right and left respectively, were in agreement on the main objective and had concluded a triple alliance with Basque and Galician autonomists, it was clear that this issue was destined to loom larger and larger in the country's politics.

War in Morocco.—Effective occupation and pacification of the Spanish zone in Morocco were still far from complete, and in guerilla warfare the tribesmen were often more than a match for Spanish troops, with whom service in Morocco had become notoriously unpopular. In 1921 Manuel Fernández Silvestre, in command at Melilla, embarked impulsively, with Alphonso's personal backing, on an operation which ended in crushing disaster at Anual (July 21). To heavy losses in men and matériel was added a forced withdrawal from the whole eastern zone, the fruit of 12 years of slow penetration. General Silvestre committed suicide.

The repercussions in Spain were profound. The government fell, and Maura was called on to face the emergency. An army of 140,000 men was sent to the rescue of the troops in Morocco the growing public demand for an inquiry the new government had at length to give way, and General Picasso was charged with investigating responsibilities, his report being submitted in due course to a committee of the Cortes. Meanwhile the juntas de defensa had reacted strongly with a campaign of threats and accusations against the Cortes, which they sought to hold responsible for the general disorganization underlying the Moroccan crisis The government retorted with a formal disbandment of the juntas, replacing them by juntas informativas subject, in theory at least, to the minister for war. But the juntas were the stronger, and early in 1922 Maura was forced from office. His successor, another Conservative, José Sánchez Guerra, was brought down in December by the debate in the Cortes on the Picasso report. The insistence in Socialist sectors of opinion that definite responsibilities attached to specified individuals and should be brought home to them charged the issue with high explosive.

A Liberal coalition followed and was confirmed in office at the general election of April 1923. The sensational feature of this was the return of Socialists for five out of the seven seats in Madrid, a success attributed by their party to the strong line that it had taken on the war in Morocco. The burden which the Moroccan problem imposed on the exchequer (an average of 358,000,000 pesetas annually in 1919–23 as compared with 75,000,000 pesetas for 1909–13 and 146,000,000 pesetas for 1913–19) was aggravated by the gradual wilting of the artificial prosperity of the war years and recurrent industrial troubles at home. For the most part, however, these problems were but facets of the basic inability of government after government to uphold the prestige of authority. In the 21 years since Alphonso's accession to the throne there had been 33 ministries.

Dictatorship of Primo de Rivera (1923-30).—In Sept. 1923 the report of the Cortes commission on the Anual disaster was ready. Several politicians were believed to be deeply involved. some as having abetted the king in his fondness for unconstitutional initiative. The reaction of the army, notoriously restive under parliamentary or civilian criticism, was awaited with some concern. Suddenly, on Sept. 13, a dramatic stroke from this quarter brought to an end the system under which the country had lived since 1875. The captain general of Catalonia, Miguel Primo de Rivera, marqués de Estella, rebelled against the government from his headquarters in Barcelona, rejecting its authority and threatening its members with jail. His manifesto declared it imperative to liberate the country from "the professional politicians, the men who for one reason or another are responsible for the period of misfortune and corruption which began in 1898 and threatens to bring Spain to a tragic and dishonourable end." "The wide net of greedy politics," he added, "has caught and imprisoned in its meshes the royal will itself." He announced the setting-up of a military directorate which would find for the Moroccan problem a "quick, dignified and sensible" solution and which would bring home responsibility promptly and justly by the formation

of tribunals "of recognized moral authority"

The premier proposed to the king strong action against the rebels, who included now the military authorities of Bilbao and Saragossa and a council of high officers in Madrid. The king asked for time for reflection, and the government resigned. Two hours later a deputation of generals was received at the palace and the king requested Primo de Rivera, who was still in Barcelona, to take office. Administratively the new directorate struck an original note in that the only minister was Primo de Rivera himself, ministerial departments being left in charge of permanent officials while the "directors" concerned themselves with specific problems as they arose. The one significant exception was the home office, which was entrusted to Gen. Severiano Martínez Anido with the rank of undersecretary of state. Public opinion received the pronunciamiento without demonstration, save for a protest from the Socialist party. The directorate declared the country to be in a state of war. A strict press censorship and a ban on political manifestations were imposed. The Cortes was dismissed, and the seizure of the files of the Commission on Responsibilities, shelving the further inquiry into the Moroccan disaster which was due to begin on Sept. 15, made clear the reason for the timing of the coup. When, two months later, the king refused to acknowledge his obligation under the constitution to convoke a new Cortes within three months of a dissolution, he made equally clear his personal responsibility in the collapse of the parliamentary regime and rendered it inevitable that the eventual fall of the dictatorship should involve that of the throne. In November king and dictator paid an official visit to Italy and expressed open admiration of Fascism,

The compelling problem was still Morocco, and it was there that the dictator won his greatest success and the nation's gratitude. The first phase, initiated in the summer of 1924, was one of cutting losses and retreating to a base line near the coast sufficient to cover Ceuta and Melilla. Primo de Rivera claimed later that in this he was interpresing the popular will, "which was weary and sceptical of any other possible solution." He himself led the operation in the field. It evoked opposition from the army and was not effected without heavy loss, but by the end of the year it was completed

Abdel Krim's sudden attack on the French protectorate in 1925, which led to combined action by France and Spain against the rebellious tribes, made possible a complete reversal of policy. The brilliant landing (Sept. 8) in Alhucemas bay, again led by Primo de Rivera in person—the other generals having refused—was a thrust at the heart of the enemy's power, and within a month Abdel Krim was in flight. The pacification of the entire Spanish zone was not completed until 1927, but already Spain's position and prestige in Africa had been retrieved.

Primo de Rivera was now tempted to consider his mission at an end and withdraw, but there was substantial popular support for the view that the dictatorship could contribute no less to the sofving of the nation's internal difficulties. He decided, however, that the military directorate had by now served its purpose and, replacing this in Dec. 1925 by a predominantly civilian cabinet, sought to base his regime on more normal political foundations. The Unión Patriótica (1926) was an attempt to form a nonparty organization of all such good citizens as would accept his own motto of "Country, Religion, Monarchy"; the "supreme national assembly" (Sept. 1927) represented a pseudo Cortes largely nominated by the dictator and given a merely advisory function.

Primo de Rivera remained the fount of power and, in his zeal for reform, was driven inevitably to abuse that power, both by attempting to force the pace and by riding roughshod over dissident susceptibilities. His successes lay accordingly in such spheres as public works, finance and public order. In the conciliation of opposition elements he failed to make headway. The Confederación del Ebro, associating the many interests concerned in the utilization of that river, was a notable innovation and the forenuner of others of the same nature. Ambitious schemes for the electrification of the railways and for road development were set on foot. Income tax was introduced in Dec. 1926 and gradually worked its way into the national finances. Morocco had ceased

to be an intolerable drain on the exchequer, and in x927. for the first time in 20 years, no loan was raised. Economic policy was directed to the correction of the heavy adverse balance of trade by stimulating home industries, canalizing investment and creating state monopolies. In the labour field an elaborate system of corporations was initiated; deriving from the Italian model, it won the approval of many Socialist leaders. An agrarian credit bank gave promise of new life to the small farmer; the other great problem in agriculture, the breaking-up of the latifundios, the regime left untouched

In 1925 the government undertook the reorganization of provinical and municipal administration. The right to levy certain rates was delegated to municipalities, with a corresponding widening of their range of action; and female and proportional suffrage were instituted in local elections. One important provision in the decree of provincial reform was the abolition of the mancomunital, the central body in Barcelona responsible for co-ordinating the work of Catalan local councils. In its Catalan policy the directorate had soon reversed the sympathetic attitude to autonomy voiced in Primo de Rivera's first utterances, which were evidently directed to winning support in Catalanist circles for his coup d'état Army opposition to any measures of Catalan devolution combined with the inherent logic of dictatorship to create an attitude agad a policy described in Catalonia as one of systematic persecution.

In external relations interest centred chiefly on the League of Nations. In 1926 Spain claimed a permanent seat on the council of the League in fulfilment of repeated promises by the French and British governments. Similar claims by Brazil, Poland, China and Persia and opposition from Germany, Sweden and others to any increase in the number of permanent seats led to a confused situation and to much resentment in Spain. At the June meeting of the council Spain's representative was ominously absent, and on Aug. 9 Spain signed a treaty with Italy stipulating mutual neutrality in the event of unprovoked aggression. Further to stress this independent mood, Primo de Rivera announced in the latter month his desire for such a drastic change in the Tangier convention as would have amounted to the setting up in Tangier of a Spanish protectorate. The assembly and the council of the League decided in December to institute a special semipermanent seat on the council for Spain. Spain refused this and gave notice of withdrawal from the League.

Negotiations with France over Tangier led finally to a number of French concessions which improved the security position in the Spanish zone of Morocco. This was a factor when, on the invitation of the president of the League council in March 1928 to reconsider its attitude, Spain announced its readiness to remain a member of the League and to accept such status on the council as the League might determine.

The year 1926 witnessed three attempts to overthrow the dictatorship by force. A military rebellion at Valencia in June, led by old General Weyler and Gen. Joaquín Aguilera, was nipped in the bud. Trouble with the artillery corps arose from a measure in July abolishing its cherished tradition of accepting promotion by seniority only as a guarantee against favouritism. A compromise settlement was, the corps claimed, broken by Primo de Rivera, and in September the artillery officers too prepared a revolt. Its failure was followed by the abolition of the corps. An ammesty later restored all but a few to their posts, but much ill-feeling remained. In November Col. Francesc Macid, exide leader of the separatist Estat Català party, launched a futile attempt to invade Catalonia from France and set up a provisional government there for the restoration of "the national sovereignty."

By the end of 1928 civil discontent with the dictatorship had combined with army unrest to render the dictator's position more difficult. Continual dissensions between dictator and king, riots in the universities and protests from intellectuals were symptoms of the general unease. The world economic crisis of 1929 was soon reflected in a serious fall in the peseta. In Jan. 1930 the finance minister, José Calvo Sotelo, resigned; and when, shortly after, the captains general of the army intimated that they no longer stood behind the dictator his fall became inevitable. On Jan. 28, 1930, Primo de Rivera admitted defeat and, laying down the reins,

crossed the Pyrenees. He was already broken in health and died in Paris on March 16.

Fall of the Monarchy.-A temporary government under Gen. Dámaso Berenguer now sought to prepare the way for a return to constitutional rule. Unrest, however, continued. Revolutionary strikes multiplied all over the country. The ranks of republicanism were swollen by all those who refused to absolve the king from his responsibility in the abrogating of the constitution, and a revolutionary committee, pledged to bring about a republic, concluded with Catalan autonomists the pact of San Sebastián (Aug 17) whereby it undertook, in return for their support, to introduce a bill for regional autonomy as soon as it was in power. The peseta, which had dropped from 29 to the pound sterling to 36 50 during 1929, fell to 51 by the autumn of 1930. An abortive military rising took place at Taca (Dec. 15). On Feb 14, 1931, the government resigned, and a new administration under Adm. Juan Bautista Aznar was charged with convoking, first, municipal elections, and then parliamentary elections for a constituent Cortes. It was generally understood, nonetheless, that the former would be taken as a test of the national temper on the one great issue and that, if the outcome were held to warrant it, the revolutionary committee would attempt to seize power.

Full results of the municipal elections of April 12, 1931, which went off quetly enough, were never published. The only figures issued showed that 22,150 seats had gone to Monarchists and 5,875 to Republicans. But in Barcelona the Republicans had a three-to-ne majority of votes; in Madrid, Niceto Alcalá Zamora y Torres, leader of the revolutionary committee, headed the poll; and most of the large cities showed republican majorities. Alcalá Zamora took the bold course of demanding Alphonso's abdication and the immediate transfer of powers to his committee. The king, after some parleying, agreed to leave Spain, but without formal abdication, and on the night of April 14 he embarked at Cartagena for France. The revolutionary committee became the provisional government of the second republic.

#### THE SECOND REPUBLIC, 1931-36

King Alphonso's action, and the fact that the army was no longer behind the monarch, allowed the establishment of the new regime without bloodshed But the initial optimism did not allow for long the illusion that the nation as a whole had turned to fervent belief in responsible democracy or achieved the competence to exercise it. Right-wing elements-army, church, landed aristocracy -were prepared to tolerate the republic so long as it respected what they believed to be their prescriptive rights. Left-wing elements-Anarcho-Syndicalists and the more extreme Socialists (Communism was as yet an insignificant force in Spain)-regarded its advent as but a stage to the overthrow of the established order of society. The regional autonomists, fortified by the pact of San Sebastián, appeared to Madrid to be intent on disrupting the national unity. Moreover, the new government, attempting to steer a middle course through all these dangers, was forced by the quantity of social problems facing it to action that of necessity invaded sphere after sphere of vested interests. The dictatorship had been merely the culmination of a long denial to the mass of the people of education in political responsibility. The republic found itself heir to the consequences, and the challenge to the political stature of the nation was as searching as that to the statesmanship and administrative ability of those now come to authority.

The whole course of the republic was marked by revolutionary strikes, anticlerical outrages and incipient revolts against the regime, now of the right, now of the left, now of the regions of the periphery. In May 1931 churches were burned by the mobs in Madrid, Valencia and throughout southern Spain. The monarchist messpaper ABC was suspended and the primate, Pedro Cardinal Segura y Sáenz, expelled from Spain for alleged monarchical indiscretions. A Communist rebellion was crushed in Jan. 1932, a rightwing rising under Gen. José Sanjurjo in the following August. The economic life of the country was seriously jeopardized by its constant subordination to political agitation.

Parliamentary elections held in June 1931 gave the left-wing parties 315 out of the 466 seats in the new constituent Cortes.

The Monarchists had I deputy. The Cortes met in July, and on Dec. 9 the new constitution was promulgated. This defined Spain as "a democratic republic of workers of all classes," with authority "emanating from the people" and no official religion. It bound Spain to respect for the rules of international law and to the renunciation of war as an instrument of national policy. Provision was made for the granting of autonomy to regions which could justify the demand for it, but any federation of autonomous re gions was forbidden. Titles of nobility were abolished. Free expression of opinion was guaranteed, and both sexes were given the vote from the age of 23. All property and wealth were declared subordinated to the interests of the national economy; forcible expropriation of property, against adequate indemnity, might be authorized by the Cortes. Marriage was to be founded on sex equality, and unions were made dissoluble "as a result of mutual disagreement or on the petition of either party." Primary education would be, not merely compulsory and tree, as nominelly under the monarchy, but exclusively lay,

Legislative authority was assigned to a unicameral Cortes, with four years as the maximum length of each parliament. The president, to be chosen by an electoral college comprising all deputies and an equal number of ad hoc members, was to hold office for six years. His powers included the nomination of the prime minister and considerable authority over the Cortes. Amendment of the constitution required an absolute majority in the Cortes and the lapse of at least four years from the date of promulgation.

The most hotly debated clauses related to religion. New measures in this field included the disestablishment of the church, the cessation from Dec. 1933 of state payment of the clergy (a form of compensation for past expropriations agreed upon in the concordat of 1851) and the submission to a special law of all religious confessions and congregations. Freedom of conscience and of worship was recognized, subject to government sanction for all public manifestations of religion. Religious orders requiring a vow of obedience to an authority foreign to the state wege to be dissolved and their property nationalized for educative and charitable purposes. Other orders would likewise be dissolved if considered a peril to the safety of the state. None might hold more property than was necessary to its sustenance, and none could engage in industry, commerce or education. Finally, it would be "permissible" for the property of all the orders to be nationalized.

These provisions occasioned a first serious political crisis. Manuel Azaña y Díaz, who as war minister had been active in reorganizing the army and reducing its officer strength, violently attacked the religious orders in the Cortes, announcing as the government's intention the dissolution in Spain, under the "vow of obedience" clause, of the Society of Jesus (this took effect on Jan. 23, 1932) and the application of the other clauses with the utmost rigour. When, after an all-night sitting, the clauses were approved by a half-empty house (178 votes to 59), the prime minister, Niceto Alcalá Zamora, and the home secretary, Miguel Maura, resigned (Oct. 14, 1931). Azaña thereupon became premier, and in December Alcalá Zamora was elected first president of the republic.

A week after Azaña's accession came the notorious Law for the Defense of the Republic, under which certain constitutional guarantees might be suspended at the discretion of a single minister. By it the home secretary was empowered to cancel meetings, dissolve associations, close clubs and suppress newspapers. Eleven "acts of aggression" against the republic were named, some in the vaguest terms, and made punishable with fines or exile. The frequent and severe invocation of this law gave Spain in many ways less freedom than it had enjoyed under Primo de Rivera.

Left-Wing Government (1931–33).—Once the constitution was promulgated, Azaña recast his government, which became predominantly Socialist. The chief measures of 1932 were the Agrarian law and the Statute of Catalan Autonomy. The agrarian problem, one of the most pressing inherited by the republic, hinged on the prevalence throughout central and southern Spain of huge estates held by absentee landlords and worked by peasants at starvation wages. The new law (Sept. 15) provided for expropriation at discretion, against payment in government bonds to the value

of the estate as assessed for taxation. Its administration was entrusted to a state-subsidized Institute of Agrarian Reform, representative of both owners and landworkers.

The movement for regional autonomy was strong in the Basque provinces (although not successful there until Oct. 1, 1936, after the outbreak of the Civil War); it was weaker among Galicians and Valencians, who were far less united in their claims. In Catalonia its urgency was extreme. The fall of the monarchy had been followed there by the immediate proclamation of a "Catalan state, in a manifesto envisaging a "confederation of Iberian peoples." Appeals from Madrid secured the substitution of the historic and less provocative term generalitat of Catalonia and resignation to the status of an autonomous region within a unitary Spain. The necessary plebiscite of the Catalan people (Aug. 2, 1931) gave a vote of 592,961 for the draft Autonomy statute and of 3,276 against. Despite considerable opposition within the Cortes and from various interests without, the statute, much revised, was approved on Sept. 9 by 314 votes to 24. By it the generalitat was empowered, among much else, to organize its own police services and be responsible for public order, to execute much state legislation and to found and maintain its own educational institutions. Catalan and Castilian were to be "co-official" languages. Though bitterly disillusioned by the mutilations suffered by the statute. Catalonia, under its presidents Francesc Macià and-on his death in 1933-Lluis Companys, became on the whole the most contented part of Spain and the least affected by strikes and revolts. The Law of Religious Confessions and Congregations, implementing the clauses of the constitution dealing with religious activities, also had a stormy passage, lasting seven months (Oct. 1932-May 1933). The proposal that teaching by the orders was to cease after 1933 made necessary alternative provision for the education of at least 350,000 children-an impossible undertaking. Already in June 1931, in Madrid alone, 50,000 children were without schools. The Cortes had authorized the creation of 27,000 new schools, 7,000 to be finished within a year; but efficient teachers could not be thus improvised. Misgivings were widespread and were shared by the president himself, who deferred signing the law until the expiry of the period allowed by the constitution.

During these two years, despite the government's efforts to cope with its many major problems, opinion had been running strongly against the left. Opposition was much exacerbated in Jan. 1933 by the ruthless handling of disturbances in the village of Casas Viejas. In April partial municipal elections, held in 2,500 rural districts, gave impressive Conservative majorities. In the autumn Azaña resigned; and, after the Radical leader Alejandro Lerroux had failed to form a government, the Cortes was dissolved and elections fixed for Nov. 19. In them the new female vote, totalling 6,500,000, could be foreseen as likely to strengthen any swing to the right.

Centre-Right Government (1933-35) .- The election results showed how deep was the disillusion with the republican experiment to date. In the new Cortes the right held 207 seats, the centre 167 and the left 99. The centre thus held the balance of power, and-with occasional infiltrations from the right-governed for the next two years, generally under Lerroux. Changes of government were numerous (seven in 1935 alone). The most important, in Oct. 1934, admitted three members of the right and precipitated revolutions in Catalonia and Asturias. In Barcelona, on Oct. 6, the generalitat again proclaimed the Catalan state of the federal Spanish republic. The central government reacted strongly. After some street fighting, Companys and his fellowministers were arrested, the Autonomy statute was annulled in fact if not formally and Catalonia was again ruled from Madrid. The extremist revolt in Asturias (Oct. 6-13), which resulted in 1,335 killed and 2,951 wounded, was liquidated with extreme severity, reprisals being taken all over Spain. It was during this period that the Falangist (Spanish Fascist) party was founded by José Antonio Primo de Rivera, son of the former dictator. The right-wing leader in the Cortes was Gil Robles.

Government policy during this biennium was directed broadly to obstructing previous legislation of the left until, in Dec. 1935, revision of the constitution should become legally possible. Thus the substitution of lay for religious schools was indefinitely postponed, the clergy had part of their state stipends restored to them,
the transfer of powers to Catalonia was delayed and a new Agrarian law treated the large landowners with respectful benevolence.
But as the date in question drew near it became evident that this
negative policy and the severity of the government's repressive
measures were in their turn producing a widespread reaction.
Azaña, arrested on suspicion after the Catalan revolt, tried, set
free and later rearrested, became a popular hero and the centre of
progressive hopes, the "strong man" who would soon return to
power and carry to completion the reforms already begun. Some
looked on him as a possible dictator of the left. By the end of 1935
the centre-right could hold on to power no longer. The president
acceded to a dissolution, and new elections were announced for
Feb. 16, 1936.

The Popular Front (Feb.-July 1936) .- From the political manoeuvring preparatory to the elections Azaña emerged as the leader not only of his own party but also of the group of parties and trade unions (Republicans, Left Republican union, Socialists, Communists, Trotskyists, Syndicalists and Anarchists) that now banded together, in spite of the previous abstention of some from political action, to ensure electoral victory for the left. This popular front, so-called after a similar French combination, won by a substantial majority (left 256, centre 52, right 165), and no sooner were the results announced than tumult broke loose. Officials dispossessed during the preceding two years clamoured for reinstatement; prisons were burst open; bands of peasants seized land and defied the law to eject them; churches, seminaries, monasteries and the offices and houses of capitalists were set on fire; there was a wave of murders by gunmen. During the first four months of popular front rule 113 general and 218 partial strikes took place, while 170 churches, 69 clubs and the offices of 10 newspapers were fired by incendiaries, who attempted to burn a further 284 buildings, 251 of them churches.

Politically, the event of this period was the deposition, on the charge of unconstitutional dissolution of the Cortes, of President Alcalá Zamora. Having tried for so long to steer a middle course, the president found himself under attack by both right and left. Azaña had gone so far as to break off relations with him. Only 5 deputies voted for the president, 238 against. On May 10 Azaña was elected, almost unanimously, as his successor.

The new prime minister, Santiago Casares Quiroga, proved wholly unable to cope with the indiscipline of the country. While his government worked out fresh measures of reform, Spanish fascism grew, much as republicanism had grown in 1930–31, as a protest against the virtual usurpation of power by extremist violence. The premier flung down a challenge: "In its relations with fascism, the government is a belligerent." The challenge was taken up, and soon violence and counterviolence had relegated the activities of the Cortes to insignificance.

On July 13, in revenge for the murder of a Communist Heutenant in the shock troops, the former dictator's one-time finance minister, José Calvo Sotelo, was arrested and murdered by men in officers' uniform. Four days later an army mutiny broke out in Spanish Morocco, led by Gen. Francisco Franco Bahamonde, which spread next day to the mainland and within 48 hours had involved the whole country in civil war. The second republic had lasted just three times as long as the first, but it ended in much the same way and for much the same reasons.

## THE CIVIL WAR, 1936-39

Everywhere garrisons revolted. In the south Seville (under Gen, Gonzalo Queipo de Llano), Córdova, Granada and Cádiz supported the rebels; in the north, all Galicia, most of León and part of Asturias, with Burgos (for three years the nationalist head-quarters), Salamanca, Valladolid, Segovia, Pamplona and Saragossa. Both in Madrid and in Barcelona the mutinies failed (otherwise there might have been no war), and the government began the struggle with the whole of eastern and most of southern Spain under its control. The Basque provinces illustrated the tug of conflicting loyalties. Vizcaya and Guipíacoa, setting autonomy above all else, threw in their lot with the regime pledged to secure

this for them; Alava sided, as also did Navarre, with the insurgents, who claimed to have risen in defense of religion and traditional values.

The nationalists, as these called themselves, representing that theirs was no mere pronunciamiento but a movimiento nacional, lost several outstanding men early, notably General Sanjurjo and Gen. Emilio Mola, killed in aeroplane crashes, and Gen. Manuel Goded Llopis, shot after the unsuccessful rising in Barcelona. They had, however, the bulk of the army, of the armed police and of the arsenals. The popular front had to rely chiefly on untrained volunteers and on such arms, outside the arsenals of Madrid and Barcelona, as the unions had been storing for their own purposes. Much time was necessary to turn improvised militias into an efficient army, and by then the nationalists had greatly improved their positions.

Casares Quiroga had resigned the premiership on the outbreak of war. President Azaña, choosing a moderate, Diego Martinez Barrio, to succeed him, found his choice vetoed by the leaders of the extremist groups. The "strong man" was compelled to give way and, from then until his own resignation in Feb. 1939, was but a figurehead. The new government, thus chosen in contravention of the constitution, lost its claim to legality, and the constitution was no longer taken seriously.

By the end of July 1936 foreign intervention had begun. From the U.S.S.R., the All-Union Central Council of Trade Unions made the republicans a first payment of 12,145,000 roubles; both the U.S.S.R. and Mexico began to send war matériel; extremist volunteers (mainly Communist) from many countries entered Spain large numbers and formed the international brigade. The nationalists received combatants, technicians and large supplies of war matériel from Italy and Germany, the fruit seemingly of prior consultation with Rome and Berlin. Realizing the danger of international complications, France approached the leading powers, and as a result formal embargoes were placed on the export of war matériel and a nonintervention committee, representing 27 nations, was set up in London. Intervention continued nonetheless throughout the war.

With the capture of Badajoz in the middle of August the nationalists were enabled to unite their northern with their southern forces; and while the former took Irún and San Sebastián early in September, the latter advanced rapidly upon Madrid. The capital was saved by the detour made to relieve the nationalist garrison imprisoned in the Alcázar of Toledo (Sept. 27). Thanks to this delay the international brigade was moved up in strength before the arrival of the nationalists on Nov. 6; and instead of submitting to a triumphal entry the Madrileños held out through a 28 months' siege.

As the threat to the capital developed, the government, now under Francisco Largo Caballero and enlarged by the inclusion of both Communists and Anarcho-Syndicalists, moved to Valencia (Nov. 7), leaving Madrid in charge of a defense council under Gen. José Miaja. President Azaña had already gone to Barcelona. There the generalitat was allowed to retain nominal power and even to take over services reserved by the Autonomy statute to the state; bur real power had passed to the unions, which collectivized industry and commerce (Oct. 28) and were responsible for the ban on public worship that only ended with final defeat,

Apart from the taking of Målaga, little was achieved by the insurgents in the winter of 1936–37, two attempts to cut the roads to Madrid conspicuously failing. In April 1937 a new and successful offensive was begun in the north, with Bilbao as its first objective. The city's "iron ring" of defenses held out for nearly two months, but on June 19 the Basque capital fell and one of Spain's two autonomous regions was again centralized. Santander was taken on Aug. 25, and Gijón, the last town to hold out in the north, on Oct. 21.

On both sides the war was marked, especially in its early stages, by a ruthlessness which astounded the civilized world. Not only were churches burned or descenated and public religious observances forbidden throughout republican Spain; ten bishops and many thousands of priests, religious and devout members of the laity were murdered in cold blood, for no political activity or

crime. The nationalists for their part organized mass executions (e.g., in Badajoz), and the Basque town of Guernica was subjected to terroristic air bombardment.

On Oct. I, 1936, General Franco assumed the leadership of nationalist Spain and outlined the features of his proposed "broadly totalitarian" rule. These included abolition of popular suffrage and of regional autonomy; equitable and graduated taxation; complete religious tolerance and a new concordat with Rome; in foreign affairs, suppression of all "Sovietic contacts" and preferential treatment for "nations of related race, language or ideology" A technical council of state was set up, to be succeeded in Jan 1938 by a cabinet on the orthodox pattern. On April 19, 1937, the two main nationalist groups—Falangists and Traditionalists—were fused into a single party, the Falange Española Tradicionalista, and all other parties were dissolved. The organization of the F.E.T. was developed four months later by the creation of a national council of about 50 members and a junta politica or party cabinet invested with considerable powers.

Much constructive legislation was promulgated even during the war, such as the Labour charter of March 9, 1938, which, under captions like "Work for All," "Remuneration and Security," "Protection and Production," gave the worker an undertaking, somewhat vaguely worded, that the "new state" had not come simply to restore the ancien régime. In agrarian policy the objective was to give every labourer a living wage and every peasant family a small holding and to improve sanitary and housing conditions in the villages. Little idea was given as yet of how such aims were to be accomplished. Another feature of the Labour charter was the creation of vertical syndicates combining into one organism, under state direction, all the elements functioning within a single service or branch of production. This departure earned for the new regime the adjective "national-syndicalist."

The republican cause suffered from internal differences much more fundamental than were to be found on the other side, and serious clashes occurred. A miniature civil war within the Civil War was caused by an Anarcho-Syndicalist rising that raged for a week in Barcelona (May 3-10, 1937). On this followed a major crisis in the Valencian government, leading to the formation of a new cabinet, under Juan Negrín, from which the Anarcho-Syndicalists were eliminated; they were not again represented in the government until April 1938. The generalitat underwent numerous crises on a smaller scale (six between Sept. 1936 and June 1937 alone), which were due also, principally, to the clash between centralizing and decentralizing groups, though, as the combat became fiercer, these drew more closely together. Largescale plot and spy trials were frequent, some of them implicating the anomalously placed Trotskyists, whose group, known as the P.O.U.M. (Partido Obrero de Unificación Marxista) was the Cinderella of the republican family.

By the end of the first year of war, General Franco held 35 of Spain's 50 provincial capitals and 119,600 sq.mi, of territory. But the republicans had as yet scarcely organized their "new army," and the struggle was far from over. The loss of the north and the consequent unification of front simplified their practical problems; and when, on Dec. 4, 1937, they launched an unexpected offensive in Aragon, it won them the city of Teruel (Jan. 9, 1938). This was to be their last, as it was almost their first, important gain and was lost once more on Feb. 22. With the spring the nationalists regained the initiative, relieved Huesca, penetrated into Catalonia, captured Lérida (April 3) and pursued the enemy up the Segre valley to Tremp. An almost simultaneous push farther south carried them to the Mediterranean (April 15), and soon they had carved themselves a corridor 40 mi. wide, threatening Castellon to the south and Tortosa to the north. Republican Spain was thus cut in two, and its government, which had removed from Valencia to Barcelona on Oct. 31, 1937, deputed General Miaja, the defender of Madrid, to act as civil and military governor of its central and southern territory.

International Activity.—The efforts made by the London committee to prevent, or at least to lessen, foreign intervention were many and complicated. Though the entry of foreign combatants was made illegal (Feb. 21, 1937), they continued to enter,

despite a coastal control system inaugurated on March 7. All the powers save Great Britain and Fiance soon withdrew from this, and Great Britain proposed its supersession by port control and by the granting to both parties of belligerent rights as soon as the withdrawal of foreign combatants already in Spain should have made substantial progress. In fact General Franco never withdrew more than 10,000 of these during the war, and the republicans, though more amenable, had not completed withdrawal at its close. Belligerent rights were, therefore, never granted.

In the summer of 1937 intensified pronationalist submarine warfare in the Mediterranean led to a nine-power conference's beingled at Nyon, Switz. This organized (Sept 14) a new system of maritime zone patrols and agreed that any submarine attacking a non-Spanish merchant ship should itself be attacked. As the fighting moved more and more toward eastern Spain, attention became increasingly centred on the bombing of Mediterranean ports, which often resulted in great damage to neutral shipping and much loss of life among civilians. Protests were made by several powers and by the Vatican against the repeated bombing of open towns (Granollers suffered 700 casualties in one air raid, and Falset, near Gandesa, was almost completely destroyed).

The idea of peace negotiations, which the powers would have supported, was rejected throughout by General Franco, who insisted on the unconditional surrender which he eventually obtained. Signs that the republicans were envisaging defeat first came in April 1938, when Negrin formulated 13 points as his irreducible minimum. At the time of the Munich conversations (Sept. 1938) these were given great publicity, and there was talk of a more moderate republican government which might canvass for an armistice. That this was not formed may have been because of a checking of the nationalists on the Ebro (July 26-Nov. 18, 1938), which gave the republicans new hopes of an indefinite prolongation of the struggle. These proved vain. Their army was exhausted, their people half-starved, their territory cumbered by about 3,000,000 refugees from the west. When at length the nationalists were able to recross the Ebro, even the severe winter could not hold back their final sweep to victory.

The End of the War.-The war had been one of lightning offensives and wearisome delays, and it conformed to type to the end. The last great offensive began on Dec. 23. A general advance in Catalonia soon developed into an attack on Barcelona which, menaced from both northwest and southwest, fell on Jan. 26, 1939, after a campaign of only 34 days. The government fled north to Figueras, where, on Feb. 1, 62 members of the republican Cortes held a meeting in the castle vault and Negrín hurled defiance at the enemy, while announcing that his 13 points were now reduced to 3. Pursued northward along the three main roads to France, the republican forces soon lost the rest of Catalonia. Hundreds of thousands of refugees poured into France, able-bodied men of military age being at first sent back, though eventually admitted and interned. When Gerona fell on Feb. 4, the government moved to a village near the French frontier. Across this, a day later, passed a succession of presidents: Azaña, Companys and the Basque president José Antonio de Aguirre.

On Feb. 28 Azaña resigned, Negrín and his cabinet returning to continue the struggle from Madrid while the nationalists prepared to move south to attack the capital. With no heating in the city, only two ounces of food daily and hundreds dying of starvation, attack proved unnecessary. On March 5 all parties except the Communists formed a new council of defense, again under General Miaja, ousting the Negrín government. A revolt against the council by Communist and other Negrín supporters broke out two days later but was suppressed after a week of heavy fighting, and the council addressed itself to preparing for surrender. On March 28, without resistance, 200,000 nationalist troops marched into the capital. By the following day the rest of republican Spain had surrendered, and Burgos radio announced that the civil war was over. It had lasted two years and 254 days and was estimated to have cost 1,000,000 lives.

# GENERAL FRANCO'S GOVERNMENT

Great Britain and France had recognized General Franco's gov-

ennment on Feb. 27; the United States followed suit on April r. A victory parade in Madrid on May 19 was followed within a few days by the departure from Spain of the German and Italian combatants; and during the summer the various ministries returned to the capital. These few months saw the first stages of reconstruction, to speed which General Franco "adopted" the most severely damaged towns and granted extraordinary credits for house building, the repair of public buildings and the rehabilitation of the transport system. The Falange, reorganized, outnumbered the Traditionalists in the government, and Ramón Serrano Súñer, appointed minister of the interior and later foreign minister, emerged as the second strongest figure in the administration. He was brother-in-law to the caudillo (leader), as General Franco was now called in his capacity as head of the Falangist party.

World War II .- With the outbreak of hostilities between Germany and the Allies in Sept. 1939, General Franco was quick to reaffirm Spain's neutrality. Six months earlier, in March, Spain had joined the anti-Comintern bloc; but a much more significant action, as it proved, was the conclusion only four days after this of a treaty of friendship and nonaggression with Portugal. This agreement, reinforced by a protocol of July 1940, seemed calculated to rule out any step capable of involving Spain in war with Great Britain's oldest ally. The Soviet-German pact came as a great shock to Spanish idealism, and the overrunning of Catholic Poland brought consternation to "the most Catholic country in Europe." Germany's attack on the U.S.S.R. in June 1941 helped to restore the perspective, and Spain dispatched its blue division of volunteers to fight by Germany's side in the Ukraine. In a speech of July 18, 1942, General Franco reiterated his stand: "Yesterday, today and tomorrow, for the countries of Europe there exists only one danger-Communism." Earlier he had promised 1,000,000 volunteers for the defense of Berlin should this ever be threatened by the Russians.

Meanwhile, Spain had used the occasion of Italy's entry into the war to alter the status of Tangier, and on Nov. 24, 1940, the administration of the international zone was formally combined with that of Spanish Morocco. England refused to recognize this unilateral action and protested against attacks on British property in Tangier; but a modus vivendi was reached on Feb. 26, 1941, when Great Britain, while reserving all rights, accepted the new situation meantime. The redefinition, likewise in June 1940, of Spain's own status as one of nonbelligerency and the emphasis laid on its new-found "will to empire" reflected confidence in an impending Axis victory and the desire to share in any redistribution of colonial territories. The presence of German troops at the Pyrenees after the French collapse weighed heavily thereafter on Spanish policy; but although General Franco journeyed to Hendaye, Fr., on Oct. 23, 1940, to meet Hitler and to Bordighera, It., to meet Mussolini four months later (Feb. 12, 1941), he succeeded in avoiding irrevocable commitments. The creation in Nov. 1940 of the Council of Hispanity, its concern being "all activities tending to the unification of culture, economic interests and power throughout the Hispanic world," was aimed at the recovery of prestige and influence in Spanish America. The atmosphere across the Atlantic, as country after country identified itself with the Allied cause, was, however, unsympathetic in the main toward Spain and its totalitarian leanings, Argentina being the notable exception.

By late 1942 the course of the war was giving General Franco cause for second thoughts. The dismissal of the violently germanophile Serrano Súñer from the foreign ministry in September was one sign that Spain was cautiously reverting from nopbeligerency to neutrality. The Allied landings in North Africa in November, followed by the German occupation of the whole of France, threatened Spain for a moment with involuntary involvement in hostilities, and partial mobilization was decreed. But the danger passed, and in December an Iberian bloc was formally cemented with Portugal. This, described by Gen. Francisco Gómez Jordana y Souza, now foreign minister (it was he who had signed the original nonaggression pact with Portugal in 1939), as "an instrument of peace capable of playing its part in international policy," confirmed the new direction; and with the collapse of

Italy in July 1943 Spain began to urge the desirability of a compromise peace, in which it aspired to play the role of mediator. The Allies however were still not convinced that Spanish neutrality was genuine and in Feb 1944 the United States, to encourage its structer observance, imposed an embargo on oil shipments to Spain. This bore fruit in an agreement of May 2, Spain giving satisfaction on various outstanding Allied grievances concerning exports of wolfram to Germany, German agents in Tangier, Italian ships in Spanish ports and the blue division.

Ostracism by the United Nations.-The ending of the war in Europe in May 1945 and the political landslide to the left that swept the continent, from Great Britain to Greece, as its first consequence confronted the Spanish regime with a position of acute difficulty. Overtures concerning Spain's claim to a voice in the peace settlement and urging the need for a western entente against Soviet expansion were rudely brushed aside. The Potsdam declaration of July branded Franco's regime as unfit to associate with the United Nations, one-third of whom were Spain's daughter nations in Latin America. In August, at an international conference in Paris on Tangier, the U.S.S.R. but not Spain being represented, Spain was given a month in which to remove its troops from the city. In that same month Mexico, which had never recognized the new Spanish regime, granted hospitality and recognition to a Spanish republican government in exile. The culmination of this general ostracism was the decision of the United Nations in Dec. 1946, by 34 votes to 6, to demand the replacement of the regime by one "deriving its authority from the governed," coupled with the recommendation that all member nations should recall their ambassadors or ministers from Madrid. Apart from Portugal and Argentina, Spain had very few friends left.

Internal Politics.-This danger had been foreseen. Once the tide of war had clearly turned, the "totalitarian state" gave way to a new term, "organic democracy". A pseudo Cortes was inaugurated (March 1943), and Franco began to drop hints of a restoration of the monarchy. In Oct. 1944 a first approach to elections took place, for the renewal of the syndical organization. This last was the residual sphere of influence of the Falangist party, whose program of national syndicalism had earlier supplied the doctrinal basis for the regime. But the party's entanglement in government was coming to be felt as an embarrassment. The secretary-general of the party, now the sole survivor of three original Falangist ministers without portfolio, was dropped in a far-reaching cabinet reorganization in July 1945, and General Franco announced to the world that the Falange no longer wielded any political power in Spain. Party control of press, radio and propaganda was transferred in August to the ministry of education. The Falangist salute was abolished by decree in the following September, and the title of caudillo was supposed to recede with the party into the background.

Relations With the Church.-The appointment as foreign minister, in the aforementioned cabinet reconstruction, of Alberto Martín Artajo, former president of Catholic Action and not a party member, was likewise aimed at foreign opinion and particularly at closer relations with the Vatican. These had lacked something of the cordiality to which the regime had from the beginning felt itself entitled. Repeal of the divorce law, restoration of religious education and of budget provision for the church, and the return to the Jesuits of their property and prerogatives had followed close on victory in the Civil War, but there had been no progress toward the new concordat promised in the program of the "new state." A modus vivendi reached in June 1941, to allow the filling of vacant sees, then numbering about 20 out of 55, merely revalidated the first four articles of the concordat of 1851. The church distrusted certain of the totalitarian implications of the regime and by 1945 was demanding—as in a pastoral letter issued (Aug. 28) by the archbishop of Toledo and primate of Spain, Enrique Pla y Deniel, to mark the end of the world waran end to the "constituent period" and a return to a constitution "in conformity with Spain's historic tradition and the degree of political education of the Spanish people."

As during the war, however, a restoration of the kingship was

still to General Franco only the last resort. In March 1945 the pretender Don Juan, third son of Alphonso XIII (who had designated him as his successor before his death in Rome on Feb. 28, 1941), had called on General Franco in a manifesto to resign, offering Spain a new constitution to be determined by popular vote, a legislative assembly, guarantees of political liberty and individual rights, recognition of regional characteristics and an amnesty. Only the mention of an amnesty provoked any response, On April 29 it was announced that all political charges against republicans were being dropped and exiles were invited to return In October came a proclamation of full pardon for all prisoners convicted of political offenses committed during the Civil War, Coming six and a half years after the end of hostilities, the detail was elequent of the animosity with which the regime had persecuted its political opponents. The execution on Oct 17, 1940, of Lluis Companys, former president of Catalonia, who had been taken in France and handed over by the Vichy government, was perhaps the blackest and most impolitic stain on the record

Political evolution did not signify any abandonment of "the fundamental principles of the state," which were declared to be sacrosanct in a charter of rights, the Fuero de los Españoles, submitted to the Cortes on July 19, 1945; and it gradually became clear that by a restoration General Franco understood, not a return to the traditional monarchy, but only such a solution for the problem of the succession as would guarantee the continuity of those principles under a guise more acceptable to public opinion. This was made explicit in a Law of Succession published on April 1, 1947, by which Spain constituted itself a kingdom and the successor to General Franco was declared to be that person of royal blood with the best right who fulfilled certain conditions, swore to observe the fundamental laws of the regime and was approved by a two-thirds vote of the Cortes. Failing such a king, a council of the kingdom, acting jointly with the government, would nominate a regent. The fundamental laws of the kingdom were defined as the Fuero, the Labour charter, the law creating the Cortes, a law of Oct. 1945 instituting a national referendum for issues transcending normal methods for the consultation of public opinion and the Law of Succession itself. Don Juan rejected the law in toto as being completely at variance with Spanish tradition, but it was approved by the Cortes on June 7 and submitted to referendum on July 6. Of more than 17,000,000 voters on the register, 82%-being 93% of those who voted-were reported to have voted in favour. In Oct. 1947 General Franco assumed the prerogative of conferring titles of nobility.

International Relations.—The exclusion of Spain from Marshall aid and the failure of repeated approaches to the United States for loans were aggravations of the acute economic difficulties that had weighed on the regime ever since the end of the Civil War. A succession of droughts and bad harvests, together with the refusal of foreign credits, caused shortages of food, of water, gas and electricity and of raw materials and plant for industry, all gravely impeding the nation's recovery and contributing to black-market abuses on a scale that threatened alike public morale and administrative efficiency. They did not suffice seriously to threaten the regime. Apathy, born of the devastation of the Civil War and the desire at all costs to avoid another, had become a major political factor. The army was still behind the regime, and the psychological effect of the ostracizing of Spain by the United Nations had been to bind Spaniards together in defiance of outside interference. By late 1950 the withdrawal of ambassadors was seen to have had the opposite effect to that intended, and on Nov. 4, by 38 votes to 10, with 12 abstentions, the United Nations rescinded its resolution of Dec. 1946, thus paying the way for Spain's return to the family of nations.

paving the way for Spain's return to the family of nations. Binitographys.—B. Sanchez Alonso, Fuentes de la historia española e hispanoamericana, 3 vol. ### POPULATION

The Iberian peninsula has such important remains of most of the phases of civilization, from the later Palaeolithic Age onward, that the racial make-up of its population is, doubtless, highly complex. It is said that, as in the Dordogne in France and on the Welsh moorlands and elsewhere, very long-headed dark types which were characteristic of western Europe in the Aurignacian period of the Palaeolithic still occur among the people of the Basque provinces and Trás-os-Montes. The peninsula, generally, is inhabited by long-headed peoples without any of the large blocks of broadheads which characterize, for example, France and Italy.

The Basque language (q.v.) is a mysterious survival in the western Pyrenees (Navarre) and in the Basque provinces to the west Catalan, widely spoken in northeastern Spain, in Valencia and in the French Roussillon, is allied to Balearic speech and

Provençal and differs from Castilian Spanish, though both are derived from Latin. Galician is akin to Portuguese.

It was usually the eastern, southern and western coasts of the peninsula that maintained contacts with ancient Mediterranean civilizations. This is one factor in the contrast in social and cultural traditions observable between Galicia and Asturias, on the one hand, and the rest of Spain. But in the main physical considerations, such as the natural differences between pluviose and arid Spain, have contributed no less than historical phenomena to

characterize and mark off one from another the great regions of

It has often been said that Roman Spain had a large population; estimates up to 50,000,000 have been ventured, but without the slightest foundation in fact. After a century of commercial expansion Catalonia had a population of only 300,000 in 1378. This region by 1940 contained about one-tenth of the total population, as a result of a relatively more rapid growth during modern times About 6,000,000 certainly seems to be the maximum figure for the population of all Spain at the close of the 14th century. On the basis of separate regional enumerations of households, the population at the end of the 16th century has been placed at 8,000,-000 Economic decay, war and pestilence probably brought about a decline in numbers during the next century. The effects of emigration to the new world were probably not so severe as contemporary writers supposed.

Modern demographic data begin with the census of 1787, which showed a population of 10,268,150 By 1857 this figure had grown to 15 495,212, and the census of 1897 enumerated 18,065,635 Relatively, Spain fell behind other European countries in the 19th century, while these countries were experiencing rapid industrialization

Population increased 26.7% from 1900 to 1930 and the ravages of the Civil War of 1936-39 did not prevent an increase (98%) in the decade 1930-40. In 1950 the population was 27,976,755, an increase of 8.1% over 1940.

Of the total population in 1950, the following 20 cities, all with more than 75,000 inhabitants, accounted for 19.8%; Madrid, 1.571.939, Barcelona, 1,278,605; Valencia, 467.989, Seville, 324,-553; Málaga, 240,899; Saragossa, 235,444; Bilbao, 225,812; Granada, 142,642; Córdova, 141,579; Valladolid, 115,157; Las Palmas de Gran Canaria, 142,116; Corunna, 122,620; San Sebastián, 90.846; Cádiz, 100,249; Santander, 85,640; Gijón, 86,523; Murcia, 84,757; Jerez de la Frontera, 80,161; Salamanca, 80,084; Santa Cruz de Tenerife, 75,412. Madrid, which was larger than Barcelona in 1920 but smaller in 1930, had recovered its position partly by means of the incorporation of adjacent townships The rate of growth in urban centres in the decade 1940-50 was uneven; Barcelona increased 18.4%; Madrid, 44.4%; Valencia, 14.2%; and Las Palmas, 45 2%. On the average the provincial capitals were 24.2% larger in 1940 than in 1930.

Religion.-Roman Catholicism is the established religion of Spain. There are o metropolitan and 61 suffragan sees. The primate of all Spain is the archbishop of Toledo. Meditation was the chief function of the orders for women, but more than half the religious houses for men concerned themselves with education.

With important exceptions, Spanish liberalism has been anticlerical. The influence of the church was curbed during the revolutionary period of 1868-74, but the restoration greatly favoured the growth of monastic and ecclesiastical institutions. Disestablishment was one of the first major objectives of the second republic in 1931. The clergy were removed from the state pay roll. religious bodies were prohibited from teaching and trading and the Jesuit order was expelled. After the civil war of 1936-39, the new regime restored the church, substantially, to its prerepublican position; confiscated property was returned to the orders, which were authorized to acquire by expropriation additional real property; religious education was reintroduced, divorce was suppressed and the cemeteries were returned to ecclesiastical jurisdiction. On June 7, 1941, the government signed an interim agreement with the Holy See regulating appointments to the Spanish hierarchy. In consultation with the papal nuncio the executive was to nominate six persons for each episcopal vacancy. The pope was then to designate three of these as a panel from which the chief of state was to fill the post. The dignitaries of the church subscribed to an oath of fealty to the state, (R. S. S.; X.)

Education.—"Every Spaniard has the right to education. whether at home or in private or public centres of instruction, at choice" (Fuero de los Españoles). A Primary Education bill of July 1945 envisaged the building of 100,000 primary schools additional to the 54,000 then in existence, of which 3,000 had been established since the Civil War. Church and other private interests may found schools; the church has the right to inspect the religious instruction which is compulsory in all All instruction is free and compulsory in theory from 6 to 12 years of age (the full primary course runs to 15) and must be given in Castilian, with separation of the sexes save in sparsely populated areas. The same official textbooks are used throughout the country. Figures for 1947-48 showed 55,111 public primary schools with 2,121,958 boys, 2,099,480 girls and 55,833 teachers. There were 53 training colleges. The officially admitted figure for illiteracy was 208%.

Secondary education follows lines laid down by a law of Sept. 1938. Of 212,210 pupils (girls 74,319) in 119 schools in 1947-48, more than one-half were at schools run by the religious orders, one-quarter at private lay schools (both fee-paying) and the remainder at free state schools. The course (bachillerato) runs from 10 to 17 years of age, terminating with a state examination conducted by the universities, to which this serves as entrance qualification. Choice of textbooks is free, subject to official approval; French is the first foreign language Teachers in state schools must be graduates, and there is again segregation of the sexes Technical secondary schools for working-class pupils were promised in a proyecto de ley of July 1949

University education is regulated by a law of July 1943. There are 12 state universities, Barcelona, Granada, La Laguna (Canaries), Madrid, Murcia, Oviedo, Salamanca, Santiago, Seville, Valencia, Valladolid and Saragossa (these serving as centres of the country's 12 educational districts), with a total of about 47,000 students, who pay fees. Madrid has seven faculties (philosophy and letters, law, political economy, science, medicine, pharmacy, veterinary science); Murcia and La Laguna, the most recent foundations, a faculty of law only, with one or two other isolated departments. Entrants must pass, in addition to the state examination mentioned above, a qualifying faculty examination. Hostels (colegios mayores) house a proportion of the students The university city of Madrid, largely destroyed in the Civil War, was rebuilt and enlarged. Religious instruction is compulsory for all students, but theological training is reserved to church seminaries. There is no university autonomy, rectors and teaching staff being state-appointed.

# GOVERNMENT, ADMINISTRATION AND DEFENSE

The "new state" promulgated no formal constitution but five fundamental laws of the nation: the Labour charter (March 1938), the Law of the Cortes (July 1942), the Fuero de los Españoles (a charter of rights, July 1945), the National Referendum law (Oct. 1945) and the Law of Succession (June 1947). With the lastnamed the formative period of the regime was held to have ended. Its article r defined Spain politically as "a Catholic, social and representative state hereby constituted, in accordance with tradition, a kingdom." General Franco, head of the state, would be succeeded eventually by a king, being a person of the blood royal acceptable to the council of the realm, the government and the Cortes or, failing such, by a regent equally acceptable.

A regency council of three, appointed ex officio, would act in an interregnum. A name for the succession might be proposed to the Cortes at any time by General Franco: in his default, by government and council of the realm acting jointly. Such king or regent must swear the fundamental laws and fidelity to the principles of the national movement. A term and conditions might be set to a regency. Kingship would be hereditary, subject to the foregoing, and restricted to males. In pursuance of this law, General Franco resuscitated in Oct. 1947 the power of the head of the state to create titles of nobility.

The council of the realm, instituted by the Law of Succession, is the supreme consultative body, advising the head of the state on all matters of his exclusive competence, such as declaring war or making peace, the choice of a successor and the exclusion of royal personages from the succession. Seven of its 14 members are ex officio, 4 elected by the Cortes and 3 nominated by the head of the state. The Cortes, established by a law of July 1942 as the "superior organism for the participation of the Spanish people in the work of the state," discusses and may propose laws, the

head of the state, who with his ministers normally initiates legislation, having the power of veto. Ministers, members of the Falangist national council (reduced from 100 to 50 in 1946), civil governors, mayors of provincial capitals and heads of universities and of other learned bodies are members (procuradores) ex officio. The head of the state nominates as many as 50 more: a further so are elected to represent provincial municipalities; and syndicalist associations elect representatives of employers, technicians and workers, in equal numbers, up to a total of one-third of the whole. Elected members serve for three years. The Cortes functions both as a whole, to consider all major legislation, and by commissions. It has no control over the government, though members may ask questions of ministers Laws of outstanding importance are submitted further to national referendum, a procedure of 1907 reinstituted in 1945, in which all citizens over 21 years of age are required to vote. The head of the state presides over the cabinet, on which the secretary-general of the Falangist party sits without portfolio. General Franco stated in 1945 that the Falange no longer wielded any political power.

Local Government.-The statutes of regional autonomy passed by the republic were abrogated after the Civil War (Navarre and Alava, however, having sided with the nationalists, were in 1941-42 confirmed in possession of their traditional concierto económico, whereby in return for a block contribution to the exchequer they enjoy rights of financial autonomy); and legislation dealing with provincial and municipal government was modified The 50 provinces-named, except for Navarre, the 3 Basque provinces and the Balearics, after their capitals-are officially regarded as intermediary administrative units between state and municipality. The provincial council (diputación) is elected partly from representatives of municipalities, partly from economic, cultural and professional bodies; councillors serve for six years, half their number changing every three years. The displacement of politically disaffected diputaciones by administrative commissions (comisiones gestoras) nominated by the civil governor, a measure introduced under the dictatorship of Pumo de Rivera, was invoked on occasion under Franco. Even without this, the civil governor, appointed by the government and responsible to the minister of the interior, effectively controls the life of the province. He is answerable for public order, through the civil guard and in the last resort the army, exercises delegated state authority and may suspend decisions of the council. The mancomunidad or interprovincial association for the integration of common interests-best exemplified in that of the four constituent provinces of Catalonia instituted in 1914 and suppressed in 1939-continues in the Canary Islands (two provinces since 1028).

A municipal law of July 1945 laid the bases of municipal administration. In towns of 10,000 inhabitants and more the mayor (alcalde) is appointed by the government, in smaller communities by the civil governor of the province. (Municipalities may be either urban or rural and number in all 9,342.) The first elections since 1936 took place in Nov.-Dec. 1949, one-third of each council (ayuntamiento) being elected from among representatives of heads of families, the other two-thirds, in equal numbers, from those of syndical organizations and of economic, cultural and professional bodies, all Spaniards over 21 years of age having the vote. The mayor is regarded as a delegate of the central government and under its orders, whether intimated directly or through the civil governor, the council tending in consequence to fill a merely advisory function. The Institute of Local Administration founded in Madrid in 1940 had among its objects the training of local government officials and employees.

Judicial System and Law.—The principle of the independence of the judiciary, proclaimed by the republican constitution of 1931, remained for some time in abeyance after the Civil War, the new regime availing itself freely of legal process for political ends, notably through the tribunal of political responsibilities (1939) and the tribunal for the repression of Freemasonry and Communism (1940). Penal legislation at this stage was often retrospective, and the oath required of all judges, magistrates and fiscals bound them first to unconditional adhesion to the caudillo,

only secondly to "the upright and impartial administration of justice" By the Fuero de los Españoles (1945) no Spaniard may be held for more than 72 hours without being handed over to a judicial authority or be sentenced unheard or for a crime antedating the law in question. Judges and magistrates are now irremovable save as is provided for by law.

"Pending the definitive organization of the administration of justice m the New State," the supreme court was reconstituted in Aug. 1938. The president and 15 of its 20 members became direct, the remaining 5 indirect. government appointees Appeals are not admitted to its administrative division (contencioso administrativo) against government decisions There are 15 regional provincial serves as court of first instance for criminal offenses Below these are the 554 district judges, who hear civil cases in first instance, and the 9,342 municipal judges (not commonly lawyers) who deal with petty offenses and minor civil issues in each municipality. The jury system exists except for military trials.

Spanish law is founded on Roman law, Gothic common law and surviving elements of mediaeval customary and local law. Modern substantive law includes the civil code of 1889, much indebted to that of France; the penal code (1870; revised 1877 and 1932); the commercial code (1885), the labour code (1926) and the codes of civil and criminal procedure (1881–82). Numerous decrees and laws of the "new state" have modified or abrogated important sections of the statute law in force in 1936.

Defense.—On the conclusion of the Civil War the army was reorganized (July 1939), the standing army consisting of eight corps in Spain, corresponding to the eight military regions (capitanias generales) of Madrid, Seville, Valencia, Barcelona, Saragossa, Burgos, Valladolid and Coruna (numbered in that order and known by number), two in Morocco, two general commands in the Balearics and the Canaries, an independent cavalry division and the general artillerly reserve, making in all 25 divisions. A ninth military region (Granada) was constituted in Jan. 1944, of one division only. General Franco, as head of the armed forces, is chief of the supreme general staff and of the national defense council. Compulsory military service (two years) was instituted in Aug. 1940. The Falangist militia was dissolved in Dec. 1943.

The navy possesses 6 cruisers built between 1923 and 1936 (from 4,686 to 10,670 tons), 22 destroyers, 9 sloops, 9 mine layers, 6 submarines, 7 mine sweepers, 16 motor torpedo boats and various smaller craft, with, in 1951, 14 destroyers, 4 submarines and 7 mine sweepers under construction. The naval dockyards are at Ferrol, Cartagena and, on a smaller scale, Cádiz. Officers and ratings, including marines, total 22,300.

An "army of the air" was created by decree of Oct. 1939, which divided Spain into five air regions, with the Balearics, the Canaries and West Africa, and Morocco as three more. There are an air branch (with special sections including parachutists) and air infantry (for nonflying duties, including aerodrome defense). Personnel are trained at an air staff college, an air force academy and various technical schools.

Of the total ordinary budget for 1951, 5,704,000,000 pesetas or 31.6% was allotted to the armed services. (W. C. An.)

## ECONOMICS

Agriculture—Spain is essentially an agricultural country. More than 55% of the population work on the land (47% as casual labourers, 29% as landowners and 16% as tenant farmers in 1948); and in 1950 approximately 50% of the national income was derived from agricultural products, which supplied the bulk of the nation's food and were the principal source of foreign currency. In general the land is arid and poor. About two-thirds of it suffers from aridity; in certain small irrigated regions round the edges of the peninsula there exists a very productive soil, but the large central tableland (Meseta) consists chiefly of moorland, steppe pasture or desert. The agricultural yield per acre was thus less than that of other western European countries. Of a total area of 50,000,000 ha, about 17,000,000 ha (of which a quarter lay fallow), were under crops, while natural pasture and

shrubs (pastos y montes) covered about 23,500,000 ha. and cultivated trees and shrubs 3 500,000 ha

The progress of agriculture was not only handicapped by climatic conditions, it was also long retarded by the resistance of the landed classes to legislation for its development. The best land was for centuries in possession of the church or nobles. Cultivation, particularly in the central provinces, was sacrificed to large-scale sheep farming. During the first half of the 19th century extensive areas of common land were purchased by the middle classes. Estimates made c. 1930 showed that in Estremadura, Andalusia and La Mancha about 7,000 landed proprietors (most of them absentees) owned 15,000,000 ac. Living conditions for the tenant farmers and the landless labourer (often unemployed) were precarious. In attempting to redress this, the republican government met such opposition that little improvement was made before the outbreak of the Civil War.

Agricultural technique remained on the whole out-of-date, and mechanization (even in the 1950s) was rare. Irrigation, which is really vital to Spanish agriculture, had long been planned. Lack of capital and later the Civil War held up its development. Until the Civil War Spain did, however, manage to be selfsupporting in many agricultural products and even to produce a surplus for export in some In the immediate years following the conflict, agricultural production fell by 20% and cereal by 30%. The decrease in cereal acreage was the result of the imposition of control prices, the lack of fertilizers and machinery. Producers found more profit in industrial crops such as cotton, tobacco, esparto, vegetables and fruits (whose prices were not controlled). Some slight recovery in cereal production took place however after 1945 under the encouragement of the government. Nevertheless, whereas before 1935 Spain was almost self-sufficient in essential foodstuffs, in later years considerable quantities (particularly of

wheat) had to be imported.

Under General Franco attempts to improve agriculture were begun by the establishment in Oct. 1939 of the National Institute of Land Settlement, a successor to the republic's Institute of Agrarian Reform. Subsequent legislation included steps to buy develop and break up among small holders various large and unproductive estates; to select certain areas for irrigation and general development; to reorganize and combine existing agricultural organizations; to introduce a more helpful system of loans; and to promote some technical agricultural training.

In 1950, however, land was still divided very unequally (45% of farming land being occupied by farms of more than 100 ha. [I ha. = 2.471 ac.] and 30% by those of less than 5 ha.), and much depended on casual labour. Most small farms were uneconomical, and the rate of agricultural unemployment was high (permanent workers in 1948 were about 8%). Spain remained the least fertilized country in Europe because of a lack of nitrogenous fertilizers (new plant, however, was increasing the supply) and one in which scientific and mechanical cultivation was still out-of-date. Hence agriculture was failing to support the workers dependent on it or to provide for the basic needs of the country as a whole.

Crop Distribution .- Wheat was by far the most important cereal of the country, being chiefly grown in parts of León, of Old and New Castile and of Aragon and, to the southwest, in Estremadura and Andalusia. Except in good years, yield before 1939 was less than 10 q. (110 metric quintals=1 short ton) per hectare (total annual production was 4,400,000 q. before the Civil War, to be compared with 2,200,000 q. in 1947 and 4,800,000 in 1951). Barley and to a lesser extent oats and rye were the next important cereals. Barley (the chief grain fodder) was the principal product of the southeast but was subordinated to other cereals elsewhere: oats and rye were grown on the poorer soils, with rye (and maize) predominating in the northwest. Rice, a staple food in Spain (the second producer in Europe) was chiefly grown in Valencia and

Murcia. Other widely grown products were pulses (again a staple diet-chiefly chick-peas, dry peas, broad beans, dry beans and lentils) and potatoes (whose output had after 1945 become inadequate for home consumption). Onions occupied an area of more than 15,000 ha, which produced nearly 3,000,000 q in 1950.

Olives were one of the greatest sources of agricultural wealth; the chief producing district was Andalusia with less important areas in Catalonia, Castile and Estremadura. Around 98% of the crop was used to extract olive oil (600 tons in 1951). The cultivation of vines (1,432,000 ha. or 3% of the total area in 1950) was widespread; table wines were produced in La Rioja district and Catalonia, dessert wines in Valencia and Málaga, sherries in the southwest and brandy in Jerez. Must wine was exported in large quantities to France for blending. Total wine production in 1950 was 1,568,000 tons.

Fruit growing and market gardening (13% of the national production) were second only to cereals in Spain, and an increasing acreage was devoted to this type of agriculture. Citrus fruits (particularly oranges), stone and soft fruits and vegetables formed the basis for a large dried or tinned export trade.

Esparto, hemp and flax (more than 1,000,000 quintals in 1950) and cotton were produced in appreciable quantities as increasing attention was paid to industrial crops. Tobacco was principally grown in Granada (30,000 tons in 1950) The silk industry from silkworms bred in Murcia and Alicante (which produce 98% of Spain's natural silk) had declined considerably by 1950 to a total

The most important industrial food crops were sugar cane and sugar beets (the latter industry being nationalized); produce was 23,300 tons of sugar cane and 153,200 tons of sugar beets in 1950 Secondary industrial food crops were peanuts, the red pepper plant and aniseed. (See Table II.)

\*Figures for these and other commodities, even when official, should be regarded simply as indicating general trends.

Livestock.-Draught and working animals in 1950 still played an important part in Spanish agricultural life, as methods of tillage were primitive, roads bad and tractors insufficient. Plowing was done by cows or oxen; mules and asses were used for transport. Horses, mules and asses were bred chiefly throughout Catalonia and the basin of mules and asses were bred chiefly throughout Catalonia and the basin of the Ebro, in the Cantabrians and in Andalusia. Sheep were bred in all parts of the country and especially in the provinces of Estremadura and Old Castile. After World War II there was a marked increase in their number. The three basic breeds were Churro (long-woolled), Merino (short-woolled) and Manchegan. The wool of the Churro (found mostly in Old Castile) is a coarse variety; the fleece of the Marino (of which Scoit were had a secreptable its owner and secreptable is only and silly and Merino (of which Spain long had a monopoly) is curly and silky and yields a fine wool. All breeds give a good supply of milk, and the Manchegan a savoury mutton.

Pigs were raised chiefly in the western provinces and in Galicia. Cat-Pigs were raised cheirly in the western provinces and in Galicia. Cat-tle were bred mostly in the northwest and north—for all purposes. Dairy farming was practically confined to this area and even there was on a small scale. In other parts of the country cows were raised for working and meat production. Table III gives figures for livestock. Fishing.—Spain has a coast line of nearly 2,000 mi.; but good natural harbours are found only in Galicia, which proviace, with its sheltered inlets, was the main source of the fishing industry. Principal fish were scripings anchouse hake tunny and bream and shellfish and

fish were sardines, anchovies, hake, tunny and bream and shellfish and crustaceans in large quantities. After the second decade of the 20th century the catch showed a steady increase: 135,600 tons in 1917; 387,000 in 1934; 481,600 in 1944; and 501,000 in 1950. By 1950 the fishing fleet consisted of nearly 40,500 vessels, totalling 238,000 tons.

TABLE III .- Livestock

		Year				Horses	Mules	Asses	Cattle	Sheep	Goats	Pigs	
1919 1935 1948	:	:	:	:	:	594,300 800,000 608,000	1,069,400 1,479,000 1,078,000	1,104,500 999,000 747,000	3,396,500 4,215,000 3,300,000	19,337,400 17,325,000 15,921,000	3,070,600 4,690,000 4,222,000	4,228,900 5,141,000 2,688,000	

Forestry.-The area occupied by woodlands in 1940 totalled 7,292,000 ha, of which 2,610,000 were under pines, 873,000 under oak, 418,000 under beech. 125,000 under poplar and 3,266,000 under miscellaneous trees Cork (of which the Iberian peninsula has almost a monopoly) was produced from the cork oak principally in Andalusia and Catalonia, and the centre of the industry was Catalonia (production 75,000 tons in 1950) Products derived from the many varieties of Spain's aromatic plants included oil of rosemary, lavender and essences of sage, thyme, sweet majoram, etc

Minerals.-Spain has, since the time of the Phoenicians, been known as a rich storehouse of mineral wealth and was, before the disknown as a non-source or infinite weath and was, before the unservery of deposits outside Europe, a leading world producer of copper, mercury, lead and iron ore. The exploitation of other regions, together with Spain's political instability, lack of capital, etc., contributed during the 20th century toward a serious decline in the relative importance of the country's output.

The more important pining areas are situated as follows: in the

The more important mining areas are situated as follows: in the extreme north, that is, in the Basque provinces and the Asturias, particularly Vizcaya, Santander, Oviedo and Lugo, where both iron ore and coal are found, in the Sierra Morena area of the southwest, that is, in the invitwestern provinces of Andalusia (Seville, Huelva, Córdoya and Jaén), where are deposits of coal, lead and copper; and finally in the Sierra Nevada region of Murcia and Almería in the southwest, which has iron ore, lead and zinc

The number of workers in the mines was (1950), 154,000.

Coal—Spain being geologically composed largely of igneous rocks, carboniferous strata are relatively rare. The largest occur in the Cantabrian mountains of the north, where the Asturian coal field (about 1,000 sq.mi.) is the most important. It produces about 75% of Spain's Smaller basins exist in the other northern provinces the south there are two main areas and several minor ones in the lower hills of the Sierra Morena Finally, small fields exist in the extreme northeast (the provinces of Barcelona and Lérida).

normeas the provinces of barceiona and bernay.

Coal production was greatly stimulated by World War I, reaching an annual production of more than 7,250,000 tons in 1918. After a temporary decline in the immediate postwar years, it again reached this mark, but the Civil War brought a setback in production. After the outbreak of World War II, production again increased considerably, reaching a total of 11,400,000 tons by 1950. This fell considerably short of national requirements and (with coking coal) was supplemented by imports from the United States, Great Britain, Belgium, France and the Ruhr. The greater proportion of Spanish coal was of an inferior quality, and the amount of anthractic small. The country had to im-

port higher-glade coal.

Iron and Copper Ore and Pyrites.—Iron ore and pyrites were chiefly found in the Cantabrian provinces, particularly Vizcaya, where ores with an average iron content of 50% occur. Large-scale exploitation began c. 1875, and in the first decade of the 20th century the area was reading a composition annually. By 1038 this figure had fallen to producing 5,000,000 tons annually. By 1938 this figure had fallen to less than 2,000,000; i.e., to somewhat less than half the national output. Iron ore was also found in central and southern Spain, but its quality was not so uniformly good nor was it as easily worked as in the north. Deposits of iron pyrites with a large sulphur content were found in Deposits of iron pyrites with a large sulphur content were found in fuelva and Seville. The total production of iron ore steadily decreased to approximately 500,000 tons in 1945 but showed some recovery in subsequent years, when more mines, which had suspended operations, were encouraged by higher prevailing prices to resume production. Spain tor many years was a leading producer of copper ore and pyrites (in which a small proportion of copper was usually found with iron). The principal 20ne was in the Sierra Morena, particularly western Seville (El Castillo), and Huelva (the region between the Odiel and the Guadiana and along the Rio Tinto). Output of copper and pyrites has varied considerably: 3,750,000 tons in 1913; 1,500,000 in 1918; 10,000,000 in 1938; 10,000 ton 1939. Output of copper or alone was 68,100 in 1940 and 252,000 in 1950 (metal content 1.2 and 5.1).

Lead Ore.-In the earlier years of the 20th century Spain was second Lead Ore.—In the earlief years of the 20th century Spain was second to the United States in the production of lead. The chief area was to the east of the Sierra Morena, particularly the districts of Linares, La Carolina (in the province of Jaén), with a less prolific one to the west in Córdova. A second area lay in the southwestern provinces of Murcia and Almeria. Deposits also existed in the north, especially in Santander.

Mercury.—Spain remained one of the chief producers of mercury, Most important were the mines of Almadén in the central province of Cludad Real (exploited since Roman times), which still possessed in 1950 immense reserves. Other lesser supplies were found in Oviedo and on the southern slopes of the Sierra Nevada in Granada. Output

and on the southern stopes of the Sterra Nevada in Granada. Output has decreased, except for brief periods, since the end of the 19th century, when the mines of Almadén alone produced around 2,000 tons annually. Other Minerals—Other mineral ores found in Spain were manganese (in the provinces of the Asturias, Huesca, Ciudad Real and Huelva), in ore together with wolfram (in the northwest) and zinc (in Santander and southeastern Murcia). Between 1918 and 1939 the production of these minerals tended to decline, but in later years their importance to armaments stimulated output. Small deposits of many other metals, such as cobalt, nickel, antimony and hismuth also occur. Spain has for many centuries been well known for its precious metals. Silver was found ailled to the lead ore, especially in Murcia, Almeria, Jaén and Córdova, and in 1950 gold was still being worked in Almeria.

Other mineral products particularly include potassic salt in the Catalan basin, sulphur at Hellen (Albacete) and Libros (Teruel), rock sulphur and asphalt. Table IV illustrates the production of the principal

TABLE IV .- Mineral Production (in metric tons)

\*Metal or salt content

Industries.- The industrial areas of Spain comprised a few small regions within the predominantly agricultural country. Industrial development was seriously retarded by long periods of internal strife and

veropinelis was seriously retardited by long periods of interial surface and of specific properties of the properties of the and of capital and a certain social and religious traditionalism. Progress was, however, stimulated by World War I, which helped the expansion of existing industries and introduced new ones. After 1978 these industries, protected by tariffs, extended still further. In the early 1930s, however, an increasing social unrest reversed that properess, and finally the Civil War left all industries in chaos and semiruin. Spain's neutrality during World War II gave the government an opportunity to restore the position somewhat

Textiles - From the late middle ages textiles were being made in the towns near the wool-producing areas, for example Segovia, Cuenca, Guadalajara, Burgos, Béjar; silk making was established in the provinces of Murcia, Seville and Valencia. But, with the advent of electricity and the importation of wool and cotton, the woollen and silk industries declined in many of these centres.

Textiles, of which cotton was by far the most important, were in the middle of the 20th century Spain's most important industry. Their principal area was Catalonia, where modern technique was first applied to the industry. There 90% of the cotton industry, 75% of the wool and most of the rayon became concentrated. Less important areas were Valencia, the Basque provinces and Andalusia The cotton industry had about 68,000 looms with more than 2,250,000 spindles in 1910, 72,000 looms (chiefly automatic and mechanical) with more than 2,000,000 spindles by 1933, and 96,400 looms with 2,342,000 spindles in 1950. The number of workers in the industry in 1950 was 162,000. Barcelona and its district was by far the most important centre of textiles. Subsidiary textile industries, again mostly concentrated in Catalonia and particularly around Barcelona, comprised flax, hemp and jute, silk and hosiery

Metallurgy.—Spain's output of minerals was only devoted in a minor degree to the domestic metallurgical industry. The principal area of this was centred on Bilbao (which produced the greater part of Spain's pig iron and steel); a second area was round La Felguera, Albana, Moreda-Gijón in the Asturias and Santander (iron and steel); a third area was in Valencia (steel); and a fourth area was in the producing regions of the Sierra Morena Production of iron and steel in 1950, though higher than in 1935, was still well below what it had been in the peak year of 1929, and the shortage was handicapping secondary industries.

industries.

Copper refineries were chiefly situated in the province of Huelva and at Córdova, lead smelters at La Carolina and Linares (province of Jaén). Lead smelting was also to be found at Cartagena and La Unión (Murcia), zinc smelting at Reocin (Santander) and Castrillon

(Oviedo).

(Oviedo). The main centres of shipbuilding were at Bilbao, Barcelona, Gijón, Valencia, Cartagena and Cádiz; locomotives, rolling stock and machinery were manufactured at Bilbao, Barcelona, Valencia and Saragossa; armament centres were found at Trubia, Oviedo, Seville and Eibar. The electrical industry, which developed steadily after 1939, was found in most of the larger towns and especially in Barcelona, Córdova, and Eibar. The number of workers in the various metallurgical industries in 1950

was about 100,000. For production see Table V.

Chemical Industry.—Domestic mineral resources formed the basis

of a diversified and growing chemical industry, though sometimes their exploitation was found uneconomical because of transport costs. Phosexploitation was found uneconomical because of transport costs. Phosphates (largely imported from North Africa) were converted into superphosphates with sulphuric acid produced from pyrites. Such production was found chiefly in the seaboard provinces of Santander, Valencia, Murcia and Barcelona. Spain was also a large producer and exporter of potassic salts and by the 1950s was trying to develop the domestic exploitation of nitrate resources, so as to lessen dependence on imports from Chile. Other Spanish chemical products included sulphuric and nitric acids, paints, dyes, pharmaceuticals and explosives.

Table V -Metallurgical Production (in metric tons)

	1935	1939	1945	1951

11050

Miscellaneous Industries - The food industries were mainly based on the milling of cereals, the production of wines and oils and the curing of fish The refining of olive oil and processing of wine were widespread; fish products were manufactured chiefly in the northern and northwestern coastal towns; sugar refining was found especially in Saragossa and Granada. Good timber resources were raie; but two valuable forestry products were cork and resin The old established papermaking industry, chiefly dependent on raw imports, was centred in the Basque provinces and Catalonia Other industries included the production of cement (more than 2,500,000 tons in 1950), china, pottery and glass, leather and tobacco

Power—Spansh; coal is chiefly of an inferior quality and the country of the country of the control of the control of the country of the count

try's resources are insufficient to meet domestic demands Deposits of oil are likewise relatively negligible, the only important source being in the province of Ciudad Real. Water power was directly used to drive

many mills throughout the country.

The use of electrical power has been progressively developed, but the potentialities of the country were incompletely realized in this respect. Total electrical capacity (principally hydraulic as a lack of coal restricts thermic production) was 1,643,000 kv.amp. in 1933 (roughly 66% hydraulic) and grew from 2,000,000 to 2,200,000 between 1939 and 1947 Output was 2,896,000,000 kw.hr. in 1933; 5,600,000,000 in 1947, 7,265,000,000 (5,430,000,000 hydraulic and 1,835,000,000 thermic) in 1950 and 9,840,000,000 in 1952.

The north of the country was the chief source of hydroelectricity,

of which one-half was derived from the Pyrenean rivers and from the Ebro and its tributaries and one-quarter from the Cantabrian rivers. Plants of a much lesser capacity supplied power drawn from the rivers of the Sieria Morena and the Sierra Nevada The national system links the former grid systems of Catalonia, Valencia and Murcia, etc. (i.e., the southeast), Madrid, Andalusia, the Asturias and the Basque provinces; and plans were launched in 1944 to increase the total capacity of the reservoirs from 5,000,000 to 18,000,000 cu.m.

Communications.—The total length of roads in Spain was around

68,700 mi. in 1950 (cf., 46,650 in 1919 and 57,200 in 1932). The well-developed Roman system had been allowed to fall into decay, and in mediaeval times the only good paved roads were the pilgrimage ways. In the latter part of the 18th century the main (royal) routes were improved, but after the Peninsular War little repair or development took place until the 1920s. The Civil War resulted in another rapid de-terioration. Traffic on the roads was relatively small, and mostly con-centrated around Madrid and Barcelona (195,000 vehicles were registered in 1950).

tered in 1950). The first Spanish railway was opened in 1848, but later construction proceeded very slowly. By 1917 the total length of lines was 9,260 mi. (of which 2,189 were narrow gauge). By 1950 this length had reached 11,200 mi (75% broad gauge); 938 mi were electrified. Railways of standard gauge (1.676 m.) were nationalized in 1949. Only a few of the main lines were double tracked, and the mountainous nature of the

country restricted load and speed capacities considerably.

The rivers of the country are unsuitable for inland navigation because of variations in flow and in gradient and on account of their use for irrigation. Very few navigation canals were constructed. The Guadalquivir is the most important waterway, being navigable by ocean-going vessels for 54 mi., to Seville. The Ebro is the chief navigable river on the east and carried a certain amount of shallow-draught

Spain's mercantile navy increased from 884,000 tons in 1914 to 1,286,000 (its highest tonnage on record) in 1924. But in relation to world tonnage, Spain's proportion fell between 1896 and 1933 from 2,7% to 1.8%. The merchant fleet suffered severely during the Civil War but received extensive government aid after 1941 and had reached

a tonnage of 1,250,000 in 1952. Commerce.—Spain's commerce in relation to its size and geographical position was relatively small. Trade was mostly with northwestern trai position was relatively small. Trade was mostly with northwestern Europe and with the United States. Mineral ores and foodstuffs were exchanged for manufactured goods. A secondary trade was maintained with Latin America and with the Spanish colonies, in which small quantities of manufactured articles were re-exchanged for raw ma-

qualitates of maintactured altitudes well: e-channinged to law ma-terials. Trade policy was closely controlled. After 2018 a high customs barrier was erected, particularly for cotton. Before 1920 Spain's imports (worth 2,000,000,000 pesetas annually) were roughly matched by its exports. From that year until after 1946 Spanish trade suffered from abnormal conditions. The international crisis of the early 1930s was followed within three years by the Civil War, and trade sank to a quarter of what it had been before 1930. During World War II there was a pronounced recovery, but for several

years after 1945 the balance of trade was again unfavourable. The government tried to improve the situation by concluding numerous bilateral trading agreements and by negotiating various foreign loans (See Table VI.) In 1952 there was again a large adverse trade balance

(See I able VI.) In 1932 there was again a large adverse have bearing.

Before 1936 Great Britain provided one-tenth of the total imports and took one-quarter of the total exports of Spain. Imports from Great Britain were chiefly wool, metal and textile goods; exports were foodstuffs and wines and mineral ores. After 1946 Spanish exports to Great Britain had an increasingly favourable balance over its imports. Exports amounted to £18,697,500 and imports to £9,695,000 in 1949; and the figures for 1951 were £40,176,000 and £1,804,000 respectively.

TABLE VI -Foreign Trade (in ooo,ooo gold pesetas)

Item	1935	1940	1942	1945	1948	1950	1951

Exports	586	394	629	881	1,107	1,190 4	1,413 6
Balance	— 289	227	+25	+18	-326	-4 8	+237 6

With the United States the balance was very unfavourable to Spain. Cotton and petroleum were the chief imports, and exports mainly food products and wine. France, Spain's second largest customer before 1940, used to supply light machinery, chemical products, fine woollen and silk textiles and luxury articles in return for fruits, wines, vegetables and mineral ores. The closing of the Franco-Spanish frontier (1946-Feb. 1948) tended to retard the resumption of this trade after World War II. Germany was before the war Spain's second largest supplier and third largest purchaser. Of other European countries, Belgium and the Netherlands were Spain's chief trading partners Trade with the Latin-American countries chiefly concerned Argentina (which supplied creals, meat and hides) and Chile (nitrates). After World War II Spain attempted to supply Argentina with minerals, textiles and shipping equipment but was unable to carry out the undertakings.

Finance.—Spain has for centuries been unable to free itself of na-

tional insolvency. From 1808 expenditure always exceeded revenue, though some appearance of solvency might have been manipulated. Rarely were estimates of revenue fulfilled, and the balance of unpaid debts carried on from year to year was considerable. National accounts worsened considerably during the Civil War and the cost of reconstruction afterward absorbed any increase in revenue. Table VII shows specimen deficits that were actually budgeted for in certain years from 1932 but fails to reveal the actual state of insolvency. Actual revenue and expenditure, for instance, were 12,278,000,000 pesetas and 14,197,000,000 pesetas (cf,12,984,000,000 pesetas and 14,223,000,000 pesetas budgeted estimate) in 1947 and 13,137,000,000 pesetas and 15,421,000 pesetas (cf,15,115,000,000 pesetas and 15,196,000,000 pesetas) in 1948.

TABLE VII .- Budgets (in ooo.ooo pesetas)

	1934	1936	1937-39	1943	1950
Revenue	4,573	4,421	4,700	9,440	17,848
Expenditure .	4,600	4,569	12,000	9,456	18,052
Balance .	-27	-148	7,300	-16	204

The gap between revenue and expenditure was narrowed after 1939 by increased taxation on income, profits and real property and in the excise duties.

excise duties.

The funded national debt on Jan. 1, 1936, was 21,850,000,000 pesetas. Funding operations after 1939 included issues of 2,000,000,000 pesetas in 4% and 2,750,000,000 pesetas at 3% on treasury loans and the conversion of former 4½% and 5% long-term state loans to 4% and of short-term loans to 3%. The public debt then amounted, in 1940, to 28,900,000,000 pesetas, of which 1,200,000,000 pesetas in 1,200,000,000 pesetas, of which 1,200,000,000 pesetas in termal debt 2,108,000,000 pesetas; treasury bonds 8,700,000,000 pesetas; and guaranteed loans 1,145,000,000 pesetas. 1,145,000,000 pesetas. In 1950 the budget authorized new issues of government bonds amounting to 2,680,000,000 pesetas for para-statal bodies and 204,000,000 pesetas to cover the budget deficit.

Prices.—Deficit financing, the enormous cost of reconstruction and

Prices—Deficit financing, the enormous cost of reconstruction and the effect of World War II contributed to strong inflationary tendencies in 1939-43, which persisted unabated in the following years. The note issue of the Bank of Spain, which reached 4,800,000,000 pesetas in 1935, rose to 9,300,000,000 pesetas in July 1940 and soared to 15,700,000,000,000,000,000 pesetas, the figure showing an increase of 4,600,000,000 pesetas in three years. Wholesale prices advanced only 39% during the Civil War, but from 1940 to 1946 the price index increased 108%. The cost of living rose over the same period 102%, although the food component of the index increased 128%. To

arrive at a true index figure, however, the official figure should probably be increased by at least 50% to 60%. (See Table VIII.) Social Welfare and Labour.—In 1908 a National institute was established for granting old-age pensions and administering a scheme of social insurance; its funds came from endowments, state subsidies and donations.

Extensive schemes for social and labour reform were envisaged by General Franco's administration in 1938. Compulsory social insurance was introduced in 1939. Based on contributions from employers and workers, it provided for family subsidies and national health benefits This was extended in 1948 to old-age pensions and sickness benefits Cost-of-living bonuses were from time to time granted to various categories of workers, and subsidies were allotted to provide employment in various agricultural areas.

ment in various agricultural areas.

Spain has a long history of tade corporations and guilds, which in the middle ages were often of a religious origin Guilds were abolished by a 10yal decree of 1836, and Spain's later domestic politics were scarcely favourable to the growth of more modern unions. Under the second republic (1931–36) the unions were unfettered by supervision

second republic (1931-39) the unions were interested by agic viscoin and became active political as well as social and economic organizations. Under General Franco a system of national or vertical syndicates (from the raw material to the marketing stage in every industry) was formed for each industry and for agriculture. These syndicates came to normen for each moustry and for agriculture. These syndicates came to control the whole economic activity of the country. In each district national syndicalist centres or horizontal syndicates backed by labour courts settle such problems as working hours, conditions of labour, wages and industrial disputes. (J\_D L)

wages and industrial disputes.

España economica (Madrid, 1948).

SPAIN, CODES OF. (For mediaeval codes, see Fuero; Germanic Laws, Early.) The codes in force at the present time cover a considerable part of the legislation of Spain.

They are: (1) The Código fundamental; 1e, the constitution of the state of 1876, which was preceded by the constitution of Cádiz of 1812, and that of 1869. (2) The Código civil, comprising the law on status, rights and duties of persons (primarily Spaniards) considered as active members of society from birth to death. It came into force on May 1, 1889, and in the same year was applied to Cuba, Puerto Rico and Philippine Islands. As in the Code Napoléon, the Roman concepts were followed. code in fact carried out the directions of the Ley de Bases of May 11, 1888. (3) The Código de comercio of 1885 which came into force on Jan. 1, 1886, following the code of 1829, was framed on the model of the French code of commerce with improvements taken from French jurisprudence and the previous local laws of Spain, such as the Novisima Recopilacion and the Ordinances of Bilbao. (4) The Código de enjuiciamiento civil (civil procedure) of Feb. 3, 1881. (5) The Código de enjuciamiento criminal of Dec. 22, 1872. (6) The Código penal of 1870. (7) The Ley Hipatecaria (mortgage law) of 1870. These have all been modified by subsequent legislation.

SPALATIN, GEORGE, the name taken by George Burkhardt (1484-1545), an important figure in the history of the Reformation, who was born on Jan. 17, 1484, at Spalt (whence he assumed the name Spalatinus), near Nuremberg, where his father was a tanner. He went to school at Nuremberg, and afterward to the University of Erfurt, where he took his bachelor's degree in 1499. There Nikolaus Marschalk, the most influential professor, made Spalatin his amanuensis and took him to the new University of Wittenberg in 1502. In 1505 Spalatin returned to Erfurt to study jurisprudence, and was welcomed by the little band of German humanists of whom Mutianus was chief. He became a teacher in the monastery at Georgenthal, and in 1508 he was ordained priest by Bishop Johann von Laasphe, who had ordained Luther. In 1509 Mutianus recommended him to Frederick III the Wise, the elector of Saxony, who made him tutor to his nephew, the future elector, John Frederick. The elector sent him to Wittenberg in 1511 and procured for him a canon's stall in Altenburg. He managed all the elector's correspondence.

Spalatin's letters to Luther have been lost, but Luther's answers remain and are extremely interesting. Spalatin read Luther's writings to the elector, and translated for his benefit those in Latin into German. He would have dissuaded Luther again and again from publishing books or engaging in overt acts against the papacy, but when the thing was

done none was so ready to translate the book or to justify the act.

On the death of Frederick the Wise in 1525 Spalatin no longer lived the Saxon court But he attended the imperial diets, and was the at the Saxon court at the Saxon court But he attended the imperial delts all the constant and valued adviser of the electors, John and John Frederick. During the later portion of his life, from 1526 onward, he was chiefly engaged in the visitation of churches and schools in electoral Saxony, reporting on the confiscation and application of ecclesiastical revenues and he was asked to undertake the same work for Albertine Saxony. He was also permanent visitor of Wittenberg university. He died on Jan 26, 1545, at Altenburg

Jan 26, 1545, at Altenburg
His writings include Annales reformationis, ed. by E. S. Cyprian
(Leipzig, 1718), and "Das Leben und die Zeitgeschichte Friedrichs
des Weisen," published in Georg Spalatins Hittorischer Nachlass und
Briefe, ed. by C. G. Neudecker and L. Preller (Jena, 1851). A list
of them may be found in A. Seelhem's George Spalatin as sichs.
Historiographer (1876). There is no good life of Spalatin, nor can
there be until his letters have been collected and edited, a work still
to be done. There is an excellent article on Spalatin, by T. Kolde, in
Herzog-Hauck, Realency-klobadus. BA viii (1766). Herzog-Hauck, Realencyklopadie, Bd. xviii (1906).

SPALATO or Spalatro: see Split or Spljet.

SPALDING, ALBERT (1888-1953), U.S. violinist, was born at Chicago, Ill., on Aug. 15, 1888. At seven he commenced his musical studies under Ulpiano Chiti in Florence, continuing them with Juan Buitrago in New York city and Narcisse Lefort in Paris. Spalding's debut was made in 1905 in Paris, where in 1906 he appeared with Adelina Patti. His first American appearance was with the New York Symphony orchestra in 1908. During World War I he served with the U.S. aviation corps in Italy. He played at La Scala, Milan, in 1919 His compositions include many works for the violin. He wrote an autobiography, Rise to Follow (1943). Spalding resumed his concert career in 1945 and died May 26, 1953, in New York city.

SPALDING, a market town and urban district in the parts of Holland, Lincolnshire, Eng. Pop. (1951) 11,031. Area, 12.2 so.mi. It is the centre of an extremely fertile fenland area, visited in spring for its flowering bulb fields; it cans locally grown fruit and vegetables and has a large beet-sugar factory and a livestock market (1938). The Welland river passes through the town by a deep channel. The parish church (once the priory church) of SS. Mary and Nicholas dates from 1284. Ayscoughfee hall (15th century, now belonging to the town) was the house of Maurice Johnson, a founder of the Spalding Gentlemen's society (1710), probably the earliest antiquarian society in England; its museum includes birds and antiquities.

SPALLANZANI, LAZARO (1729-1799), Italian priest and biologist, was born at Scandiano in Modena on Jan. 10, 1729 At the age of 15 he was sent to the Jesuit college at Reggio di Modena, and soon went to study law at the university of Bologna, where his kinswoman, Laura Bassi, was professor of physics; she, it is said, first interested him in science. After taking orders, he was professor at Reggio, Modena and, under Maria Theresa, at Pavia, where he enriched the museum by the collections from journeys along the shores of the Mediterranean. In 1785 he was invited to Padua, but his sovereign doubled his salary and gave him leave to visit Turkey, where he made many observations. He visited Vesuvius and Sicily in 1788 and embodied his researches in Viaggi alle due Sicilie (1792-97).

Spallanzani was a skilled experimenter in physiology. He studied

the circulation of the blood, respiration, digestion, the senses of bats, the electricity of the torpedo, the breeding of cels and the regeneration of different appendages of Amphibia, following the muscles, nerves and bones with a microscope. By filtering the semen he proved that spermatozoa were necessary for fertilization in different animals. He spermatozoa were necessary for tertuization in dinerent animais. He artificially inseminated a bitch. He supported the preformation theory of embryology. In a controversy with J. T. Needham he disproved (1765) the spontaneous generation of Infusoria, which did not develop in vegetable infusions that had been boiled long enough and kept in properly closed vessels. His great works are the Prodomo di un'opera da imprimersi sopra le reproduzioni animali (Modena, 1768); and Dissertazioni de fisica animale e vegetabile, 2 vol. (Modena, 1780). He died at Pavia on Feb. 12, 1799. (A. C. Ce.)

SPANDAU, a suburb of Berlin, Germany. Pop. (1933) 146,-408. Spandau is one of the oldest places in the Altmark, and received civic rights in 1232. It afterward became a favourite residence of the Hohenzollern electors of Brandenburg, and was fortified in 1577-83. In 1635 it surrendered to the Swedes, in 1806 to the French and in 1813 to Prussia. Spandau was the chief garrison town of Prussia and contained the imperial war treasure. It was

united with Greater Berlin in 1920.

SPANDRIL, SPANDREL in architecture a space between any arch or arch-like form and the horizontal moulding or beam above it; also, in an arcade, the wall surface between two adjacent arches and any horizontal member above them. In buildings of skeleton construction such as steel-framed skyscrapers, the term refers to the space between the top of a window and the sill of that in the story above.

SPANGENBERG, AUGUST GOTTLIEB (1704-1792), German Monavian bishop, Count Zinzendorl's successor, was born on July 15, 1704, at Klettenberg, on the south of the Harz mountains, where his father. Georg Spangenberg, was court preacher and ecclesiastical inspector of the countship of Hohenstein. Left an orphan at the age of 13, he was sent to the Gymnasium at Ilefeld, and from there in 1722 he passed to the university of Jena to study law. Professor Johann Franz Buddeus (g v) received him into his family, and a stipend was procured for him.

He soon abandoned law for theology; he took his degree in 1726 and began to give free lectures on theology. He also took an active part in a religious union of students, in the support of the free schools for poor children established in the suburbs of Jena and in the training of teachers In 1728 Count Zinzendorf visited Jena, and Spangenberg made his acquaintance; in 1730 he visited the Moravian colony at Herrnhut A collegium pastorale practicum for the care of the sick and poor was in consequence founded by him at Jena, which the authorities at once broke up as a Zinzendorfan institution. But Spangenberg's relations with the Moravians were confirmed by several visits to the colony, and only the accident of an unfavourable appeal prevented his appointment as chief elder of the community.

His free lectures in Jena led to an invitation from Gotthilf Francke to the post of assistant professor of theology and superintendent of schools connected with his orphanage at Halle. He started work there in Sept. 1732, but differences between the Pietists of Halle and himself soon became apparent. He found their religious life too formal, external and worldly; and they could not sanction his comparative indifference to doctrinal correctness and his incurable tendency to separatism in church life. Spangenberg's participation in private observances of the Lord's Supper and his intimate connection with Count Zinzendorf brought matters to a crisis. He was offered by the senate of the theological faculty of Halle the alternative of doing penance before God, submitting to his superiors and separating himself from Zinzendorf, or leaving the matter to the decision of the king, unless he preferred to "leave Halle quietly," The case came before the king, and, on April 8. 1733. Spangenberg was conducted by the military outside the gates of Halle.

At first he went to Jena, but Zinzendorf at once sought to secure him as a fellow labourer, though the count wished to obtain from him a declaration which would remove from the Pietists of Halle all blame with regard to the disruption. Spangenberg went to Herrnhut and found among the Moravians his lifework, having joined them at a moment when the stability of the society was threatened. He became its theologian, its apologist, its statesman and corrector, through 60 long years of incessant labour.

For the first 30 years (1733-62) his work was mainly devoted to the superintendence and organization of the extensive missionary enterprises of the body in Germany, England, Denmark, Holland, Surinam, Georgia and elsewhere. It was on an island off Savannah that Spangenberg startled John Wesley with his questions and profoundly influenced his future career. One special endeavour of Spangenberg in Pennsylvania was to bring over the scattered Schwenkfeldians to his faith. In 1741-42 he was in England collecting for his mission and obtaining the sanction of the archbishop of Canterbury. During the second half of this missionary period of his life he superintended as bishop the churches of Pennsylvania, defended the Moravian colonies against the Indians at the time of war between France and England, became the apologist of his body against the attacks of the Lutherans and the Pietists and did much to moderate the mystical extravagances of Zinzendorf, with which his simple, practical and healthy nature was out of sympathy. The second 30 years of his work

(1762-92) were devoted to the consolidation of the German Moravian Church. Zinzendorf's death (1760) had left room and need for his labours at home. At Herrnhut there were conflicting tendencies, doctrinal and practical extravagances, and the organization of the brethren was very defective. In 1777 Spangenberg was commissioned to draw up an idea fidei fratrum, or compendium of the Christian faith of the United Brethren, which became the accepted declaration of the Moravian belief. As compared with Zinzendorf's own writings, this book exhibits the finer balance and greater moderation of Spangenberg's nature. In his last years Spangenberg devoted special attention to education He died at Berthelsdorf, on Sept. 18, 1792. In addition to the Idea fidei tratrum. Spangenberg wrote, besides other apologetic books, a Declaration über die seither gegen uns ausgegangenen Beschuldigungen sonderlich die Person unseres Ordinarius (Zinzendorf) betreffend (Leipzig, 1751), an Apologetische Schlussschrift (1752), Leben des Grafen Zinzendorf (1772-75); and his hymns are well known beyond the Moravian circle.

SPANISH-AMERICAN ARCHITECTURE. The high quality as well as the great quantity of colonial architecture in Spanish America establish it as a major contribution of the New World to the history of civilization. The zeal and power of the Spanish church were abetted by the wealth of the colonies in the construction of sumptuous ecclesiastical buildings. Skilled Indian labour also contributed to the early development of large-scale programs in both religious and domestic architecture. Types of buildings and styles are Spanish in origin, although local conditions produced modifications. Occasional Indian influence in remote regions is limited chiefly to decorative details and to a flat primitive method of carving. In centres of European culture such as Santo Domingo, Mexico City, Ouito, Lima and Cuzco architectural styles are contemporary with those in Spain. Mediaeval traditions survive, however, especially in monastić structures, even in the 17th century, the persistence of late-Gothic ribs in the vaults of churches being the most striking feature. Spanish-Moorish elements (Mudejar), such as wooden ceilings in geometric patterns. coloured tiles, the rectangular frame of an arch (alfiz), and the trefoil arch, were popular throughout Spanish American architecture, and they account for much of its exotic character.

Sixteenth Century.- In Santo Domingo, site of the first Spanish settlement, is preserved the earliest cathedral (1521-41), which has a superb Spanish Renaissance façade and a Gothic interior. In Mexico, large building campaigns (c. 1550-1600) were carried out by Franciscan, Augustinian and Dominican friars. Their monasteries generally have a huge vaulted church of single nave, cloister and monastic buildings, based upon Spanish proto-types. The large atrium yard and the "open chapel" for religious services out-of-doors are special features developed in America to accommodate crowds of Indians, as at Acolman, Cuernavaca, Huejotzingo, etc. Portals display a wide variety of styles, including mediaeval and Renaissance elements and occasional Indian influences. The largest Mexican cathedrals, those of Mexico City (1563-1813) and Puebla (1575-1690), have the rectangular basilican plan and other features of the Andalusian Renaissance. Their long delayed completion, however, resulted in a mixture of styles. Important monuments of Peru were destroyed by earthquakes, the surviving structures of modest character being found in Ayacucho, on the shores of Lake Titicaca and in Sucre (Bolivia). Vaulted churches were virtually unknown in South America until the 17th century. In Quito (Ecuador) the Franciscan and Dominican monasteries are notable for their cloisters and Mudeiar ceilings, and the cathedral (1562-1572) is an example of Andalusian Gothic-Mudejar construction.

Seventeenth Century.—Notably sober is the architecture of the first half of the 17th century, preserving the late classical style of the Spanish architect of the Escorial, Juan de Herrera. This austerity characterizes San Agustín and Santo Domingo in Puebla as well as the façade of the cathedral. Most awesome is the cathedral (1598–1654) of Cuzco, Peru, rectangular in plan, and Herreresque in its sobriety except for the early Baroque portal. With the building of the Jesuit church there, the handsome façade being designed in 1664 by Diego Martínez de Oviedo, Cuzco created the first school of late Baroque architecture in the Americas. The city abounds in handsome churches and palaces, built of Andean stone in the second half of the 17th century, and it is in many respects unrivalled in America. At Lima the rebuilding of the monastery of San Francisco (1657–73) brought a new wave of Hispano-Mauresque (Mudejar) influence in the geometric designs of the plaster work. The main portal (1674) of the church inaugurated in that city the late Baroque type of façade, closely resembling a carved altarpiece.

In Bolivia the chief architectural centre was Sucre, where Gothic vaults pessisted, but otherwise both religious and domestic buildings adhered to simple classical designs. The Jesuit church in Bogotá, Colombia, owes its Italianate classicism to the architect, Father Coluccini, who came from Italy. The greatest masterpiece of Jesuit architecture in America is, however, the church in Quito, Ecuador. There the Mudejar patterns, which stand out in gold against a red background, make the interior (1605–89) of the church unforgettably sumptuous. More provincial, though extremely colourful Mudejar interiors, are characteristic of the monastic churches of Tunja (Colombia). Due to the splendid designs of its monastic buildings, Quito stands with Cuzco as one of the major schools of architecture in South America.

Bighteenth Century.—The final stage of Baroque architecture in Spanish America is generally distinguished by richly sculptured façades, whereas the interiors often remain sober settings for resplendently carved and gilded altarpieces. The late Baroque altar of spiral columns was imported from Spain about 1650-60. Its translation into stone on the façade of a church first occurred (1697-1704) in South America in La Merced at Lima, to be followed by San Agustín in Lima and three splendid churches in Cajamarca.

In this period appeared in southern Peru and Bolivia a school of architectural decoration characterized by native Indian contributions in the primitive manner of carving and in the introduction of non-European ornament. The crossbred style is known as mestizo, because it, like the people, is compounded of European and native Indian stock. Evidences of Indian contribution are also found in Mexico throughout the colonial period, and there exist parallel phenomena in Central America. The first examples of the independent Peruvian-Bolivian style are preserved in Arequipa where the façade (1508) of the Jesuit church represents a culminating point in the tapestrylike treatment of the walls. A masterpiece is Santiago at Pomata (about 1509–1722), but most extraordinary of all is the façade of San Lorenzo at Potosí. Among other fine examples are the façade (1700–07) of the Jesuit church at Potosí and San Francisco (1753–72) at La Paz.

Argentina lay in the outer periphery of the Spanish colonies, and its early architecture consisted of provincial chapels of ruble and adobe, with the exception of the Jesuit monastery (1654–79) at Córdoba. In the 18th century two Italian Jesuit architects, Blanco and Prímoli, established the spacious style of the Italian Baroque in the Jesuit estates of Alta Gracia and Santa Catalina near Córdoba, and in El Pilar at Buenos Aires.

Baroque architecture reached its climax in Mexico with lavishly carved façades in which the tapering pilaster (estipite) is a distinguishing feature. Introduced in the capital in the Sagrario façade (1749-68) under the architect Lorenzo Rodríguez, it spread like fire and reappeared in La Santísima, in the Jesuit semi-ary at Tepozotlán, in the churches of Guanajuato, etc. The school of Puebla maintained independence in producing an extra-ordinary array of brilliantly coloured exteriors of glazed tiles, both in churches and in countless palaces. Mixtilinear contours in doorways, windows, and roof levels create highly picturesque effects in Mexican buildings of this period.

Throughout Spanish America, cities were built on a gridiron

plan with rectangular plaza in the centre and covered sidewalks (portales) of Mediterranean tradition. Houses, large or small, were arranged about a central patio. Although handsome domestic buildings exist throughout the continent, special mention should be made of those in Mexico City, Puebla, Tunja, Potosí and Cuzco. Most remarkable civil edifices, such as the custom house and viceregal palace, survive in Mexico City, whereas elsewhere only the royal mint at Potosi (1753–73) and the government palace (1764) in Antigua, Guatemala, are comparable in importance. Spanish colonial architecture came to an abrupt end with the triumph of Neoclassicism (1800) Thereafter European revivalism prevailed until the advent (1930) of the international style of steel, concrete and glass with Argentina and Mexico in the vanguard.

E. Wethey, Colonial Architecture and Sculpture in Peru (Cambridge, 1940).

SPANISH-AMERICAN LITERATURE. For more than 300 years after its discovery Hispanic America was culturally as well as politically an Iberian colony. The conquistadors and the missionaries who accompanied them wrote the first Spanish-American literature in the letters and reports which they sent home telling of their victories with sword and cross. Foremost among these are the letters from Columbus to the Spanish court and the five dispatches, so-called Cartas de relación, sent by Hernán Cortés (1485-1547) to the emperor, Charles V. Longer accounts of the conquest and descriptions of the New World, La conquista de México v de la nueva España by Francisco López de Gomara (1510-60), Verdadera historia de la conquista de la Nueva España by Bernal Díaz del Castillo (1492-1584), and Sumario de la natural y general historia de las Indias by Gonzalo Hernández de Oviedo y Valdés (1478-1557) followed. The oppressed Indians found a champion in Fray Bartolomé de Las Casas (1474-1566) whose Brevisima relación de la destrucción de las Indias appeared in 1552. Later, one of their own blood, the Inca Garcilaso de la Vega (1540?-1616), told their story in his Comentarios reales (Pt. I 1609, Pt. II 1617).

Before the end of the 16th century Mexico and Lima had become centres of intellectual activity. A printing press was set up in Mexico in 1539 and charters for a university were granted both cities in 1551. The extent to which letters were cultivated at the viceregal courts may be inferred from the fact that in a contest held at Mexico in 1585 more than 300 poets took part. The outstanding poetic achievement of this period was the epic of the conquest of Chile, La araucana (1569-89), written by a young Spanish officer, Alonso de Ercilla y Zúñiga (1533-94), who himself had taken an active part in the exploit and been moved by the valour and dignity of his enemies. The same material was used by a native Chilean poet, Pedro de Oña (1570-1643), in his Arauco domado (1506) with less distinction. These epics and the long descriptive poem, La grandeza mexicana (1604) by Bernardo de Balbuena (1562-1627), are significant in that, though they follow the European fashion in poetic form-Ariosto's epics were then in vogue-they deal with genuine American themes of which the authors had expert, first-hand knowledge.

The cult of Góngora, which in the 17th century superseded in Spain that of the Italian poets, called forth the first important piece of literary criticism in America, the Apologético en Javor de D. Luis de Góngora (1694) by Juan de Espinosa Medrano, as well as the lyrics and prose selections of the anthology, Ramillete de varias flores poéticas (1675), collected by Jacinto de Evia (b. 1636). The great Mexican-born dramatist, Juan Ruiz de Alarcó, (c. 1580-1639)—generally counted among the poets of Spain, since his plays were all written and published in that country—is comparatively free from the affectations of this school. His gifted comparative, the "tenth Muse," Sor Juana Inés de la Cruz

(1651-95), shows its influence in some of her works, but the fame of this extraordinary woman rests chiefly on the simpler beauty of her autobiographical lyrics.

No hterature of outstanding value was produced in Spanish America during the 18th century. The later years of the century were years of political unrest. Revolutionary pamphlets imported from France urged the cause of independence. When the wais of liberation broke out in the first decades of the 19th century, America produced pamphleteers of its own, among them the fiery Benardo de Monteagudo (1785-1825) of Argentina and the Mexican satirist José Joaquín Fernández de Lizardi (1776-1827), publisher of the journal El pensador mexicano (1812) and author of the first real American novel, the picacesque tale El periquillo-sarmento (1816). Simón Bolívar (1783-1830), the great liberator, nourished from childhood on the works of Rousseau, wrote distinguished prose in his Discourses and letters composed during the campaigns.

In all parts of Spanish America the victories of the revolution called forth patriotic verse. La victoria de Junin. Canto a Bolivar by José Joaquin Olmedo (1784-1847) of Ecuador was the most successful of these poems. Among other talented poets who wrote in the cause of liberty were José María Heredia y Heredia (1803-29) of Cuba, best known for his ode to Niagara; José Fernánce Madrid (1784-1830) and Luis Vargas Tejado (1803-29) of Colombia; Juan Cruz Varela (1794-1839) of Argentina; and Anérés Bello (1781-1865, of Venezuela. Bello, who was to become later one of Spanish America's greatest scholars, is remembered, however, not for his political verse but for his Silva a la agricultura de la zona torrida.

At the close of the revolutionary period the poets of America came under the influence of the prevailing European literary fashion, romanticism. Standing, as it did, for freedom, individualism and emotional intensity, romanticism seemed made to fit Spanish-American conditions and temperaments. Many of the poets were political as well as literary "liberals" The young Argentine, Esteban Echeverría (1805-51), who had returned from a stay in Paris in 1830, published the first important romantic work, the poem of the pampas, "La cautiva" (in Rimas, 1837). Echeverría and his associates-among them. Juan María Gutiérrez (1809-78), compiler of the anthology, América poética, and José Mármol (1818-81), author of El peregrino, a South American Childe Harold, and of the famous political novel, Amalia (1851)-as political refugees from the tyranny of Rosas, carried the new fashion from Argentina to Uruguay and Chile. In Mexico Ignacio Rodríguez Galván (1816-42) and Fernando Calderón y Beltrán (1809-45) followed the Spanish romantics Espronceda and Zorrilla as lyric poets and dramatists. Though the favourite genre of the romanticists was lyric poetry, two important novels were produced during this period, Mármol's Amalia and the Maria of Jorge Isaacs (1837-95). Later phases of romanticism were represented in Mexico by Ignacio Manuel Altamirano (1834-93) and in Argentina by Olegario Victor Andrade (1838-83) and Juan Zorrilla de San Martín (1855-1931), author of the Indian epic, Tabaré.

Two indigenous literary genres without European prototype also were developed during the latter half of the 19th century. One of these was the so-called "gaucho poetry" of Argentina and Uruguay. The life of the gaucho had long been the subject of folk tale and ballad. It had been used in the Dielogues of Bartolomé Hidalgo (1788–1823). It had been given serious study in the great work of Domingo Faustino Sarmiento (1811–88), Civilización y barbarie: Vida de Juan Pacundo Quiroga. It now received epic treatment in José Hernández's Martín Fierro (1872) and La vuelta de Martín Fierro (1879). It formed the basis of Estanislao del Campo's masterpiece Fausto (1866).

The other genre, which appeared at about the same time, was the creation of the Peruvian Ricardo Palma (1833-1910), who in his famous Tradiciones peruanas (first series 1872) elevated the historical anecdote to the realm of art.

In 1888 a Nicaraguan poet, Rubén Darío, published a volume of poems and short stories called Asul which had a profound effect on the letters of the Spanish-speaking world. It was the basic work of the modernista movement, a cult of beauty which urged

the enrichment of poetry with new forms, new rhythms, new words. Precursors of the movement may be found in the Cuban poet and patriot José Martí (1853–95), in the Mexican Manuel Gutiérrez Nájera (1859–95) and in the Colombian José Asunción Silva (1865–96). Dario was its high priest and perhaps the greatest poet which Spanish America has produced. Other famous adherents of the movement were Leopoldo Lugones (1874–1938) of Argentina, Amado Nervo (1870–1919) of Mexico and Julio Herrera y Reissig (1875–1910) of Uruguay.

In reaction to the formalism and the escapist tendencies of the modernistas there soon appeared in Spanish America a movement which concerned itself with the subject matter of literature. This was variously known as "Americanismo," "Criollismo" or. "New Worldism" In its broadest aspect it was essentially a gospel of nationalism and racial solidarity. Its prophet was the Uruguayan José Enrique Rodó (1872–1917), the "Latin Emerson," who wrote his message in the essay Ariel (1899). It was introduced into poetry by José Santos Chocano (1875–1934) and into the drama by Florencio Sánchez (1875–1910) and the lesser playwrights of the teatro criollo of Argentina and Uruguay. It has been most fruitful in the development of prose fiction.

Indeed, the remarkable development of prose fiction in Spanish America is the most significant phenomenon of the 20th century. Some eminent poets have appeared, notable among them the former Chilean schoolmistress Gabriela Mistral (Lucila Godoy Alcayaga) (1889—), winner of the Nobel poetry prize in 1945; Delmira Agustini (1886—1914); Juana de Ibarbourou (1895—

); Alfonsina Storni (1802-1038); Enrique Banchs (1888-); Rafael Arévalo Martínez (1884-); Pablo Neruda ). But as the countries of South America have de-(1904veloped economically and industrially, their writers have become increasingly concerned with the inequalities and injustices in their social environment and have found the novel or the short story the best medium for the expression of this concern. All phases of contemporary life have been reflected in fiction: ranch life in the works of Carlos Reyles (1868-1938), Ricardo Güiraldes (1886-1927), Javier de Viana (1872-1926); life on the plains of Venezuela by Rómulo Gallegos (1884-); life in the tropical jungle by José Eustasio Rivera (1889-1928); life in the city by Manuel Gálvez (1882-); life in a Peruvian Indian village ); life in the Uruguayan forests by by Ciro Alegría (1909-Horacio Quiroga (1878-1937). In Mexico an influential group of "novelists of the revolution," Mariano Azuela (1873-1952), Gregorio López y Fuentes (1895-) and Martín Luis Guzmán ) dealt realistically with the agrarian, industrial, racial and religious problems resulting from the upheaval in Mexican society which began in 1910.

The Spanish Civil war (1936-39) and World War II brought a conflict of loyalties and increased emotional tension to many countries of Spanish America, but they produced no new literary trends that were immediately discernible. Prose fiction dealing with contemporary problems continued to be the favourite literary medium. There was evidence of a heightened awareness of the importance of political and racial problems and a strong conviction on the part of many writers that their countries have an important contribution to make toward the solution of these problems.

SPANISH-AMERICAN WAR OF 1898. On Feb. 15, 1898, the U.S. battleship "Maine" was destroyed in Havana harbour by an explosion, with a loss of 266 lives. An American board of inquiry made an extensive examination of the wreck, and reported to the navy department on March 21 that the explosion was caused by an exterior mine, the principal reason for this decision being the upheaval of the ship's bottom. On April 20 President McKinley approved a resolution demanding the with-

drawal of Spain from Cuba and setting noon of April 23 as the latest date for a reply. Before this could be delivered by the American minister in Madrid, the Spanish government sent him his passports. On the 22nd the president declared a blockade of Cuban ports; on the 24th the Spanish government declared war; and on the 25th the United States congress declared that war had existed since the 21st. The joint resolution of congress of April 20 had declared that relinquishment by Spain of authority in Cuba was the object of American action; the struggle thus naturally centred about the island and all operations were thus at hand. The regular United States army, the only available force until war was declared and a volunteer force was authorized, had been assembled at Tampa, Fla., New Orleans, La., and Chickamauga, Ga., but until the control of the sea was decided, the army could not prudently be moved across the Strait of Florida The Spanish fleet under Pascual Cervera, which had left the Cape Verde Islands for the West Indies, was the real objective of the navy, and had to be settled with before any military action could be undertaken. Accordingly Rear-Admiral William T. Sampson left Key West early on April 22, and began the blockade of Havana and the north coast of Cuba. His North Atlantic squadron of 28 vessels of all kinds, of which the armoured cruiser "New York" (flag), the battleships "Iowa" and "Indiana," and the monitors "Puritan," "Terror" and "Amphitrite" were the most important, and which included 6 torpedo boats, was increased to 124 vessels by July 1.

Battle of Manila Bay .- In the Pacific, the American squadron—the protected cruisers "Olympia" (flagship of Commodore George Dewey), "Baltimore," "Raleigh" and "Boston," the small unprotected cruiser "Concord," the gunboat "Petrel," the armed revenue cutter "Hugh M'Culloch," with a purchased collier "Nanshan" and a purchased supply ship "Zafiro"-left Hong Kong at the request of the governor and went to Mirs bay, some miles east on the Chinese coast. Ordered (April 25) to begin operations, particularly against the Spanish fleet, which he was directed to capture or destroy, Dewey left Mirs bay on the 27th, and arrived off Luzon, in the Philippines, on April 30. The Spanish admiral Montojo anchored to the eastward of the spit on which are the village and arsenal of Cavite, in a general east and west line, keeping his broadside to the northward. His force consisted of the "Reina Cristina," the "Castilla" (an old wooden steamer which had to be towed), the "Isla de Cuba" and "Isla de Luzon" (protected cruisers of 1,050 tons), the "Don Juan de Austria" and the "Don Antonio de Ulloa" (gunboats of about 1,150 tons) and the "Marques del Duero" (of 500 tons).

Dewey passed into the Boca Grande, paying no attention to rumours of torpedoes, and at midnight passed El Fraile. When he sighted the Spanish squadron to the southward he stood down in column with the "Olympia," "Baltimore," "Raleigh," "Petrel," "Concord" and "Boston" at 400-yd. intervals. When within 5,000 yds. he ported his helm, and at 5:41 A.M. opened fire. He stood westward along the Spanish line, using his port batteries, turned to starboard and stood back, gradually decreasing his distance to 2,000 yds. At 7:35 Dewey withdrew and gave his men breakfast. Before he re-engaged at 11:16 the "Cristina" and "Castilla" bad broken into flames, so that the remainder of the action consisted in silencing the Cavite batteries and completing the destruction of the smaller Spanish ships. The victory was complete. All the Spanish ships were sunk or destroyed. The injury done U.S. ships was practically nil. The Spanish lost 167 killed and 214 wounded, out of a total of 1,875. The Americans had 7 slightly wounded out of 1,748 men in action. Dewey took possession of Cavite and awaited the arrival of a land force to capture Manila.

Santiago.—Cervera had left the Cape Verde Islands on April 29 with four armoured cruisers, the "Almirante Oquendo," "Inanta Maria Teresa" and "Vizcaya" (sister ships of 7,000 tons) and the "Cristobal Colon" (same size; differently equipped) and three torpedo-boat destroyers. On hearing (May 1) of Cervera's departure, Sampson went east to San Juan, Puerto Rico, with the armoured cruiser "New York," the battleships "Iowa" and "Indiana," the cruisers "Montgomery" and "Detroit," and one torpedo boat. He reached San Juan on the 12th. Cervera was not present, and Sampson at once started back for Havana. Cervera

reached Santiago de Cuba early on the 10th without being sighted en route. It was not until the end of the month that the American fleet was assembled before the harbour. An attempt was made to sink the collier "Merrimac" in the entrance channel, which was less than 200 ft. broad in parts available for ships. The preparations for a quick sinking were chiefly carried out by naval constructor Richmond P. Hobson, who went in, in the early morning of June 3, with a crew of seven men. The steering gear was disabled by a shell. and the ship drifted too far and was sunk in a broad part of the channel where it did not block the egress of Cervera's squadoron.

On June 6 the hatteries at the entrance were bombarded and their weakness was ascertained. Sampson thereupon placed, every evening, a battleship close in, with a searchlight turned on the channel, making it impossible for the Spanish squadron to escape by night. The port of Guantánamo, 40 mi. east of Santiago, was occupied and was used thereafter as a base and coaling station.

The Land Campaign .- When war was declared the total military forces of the United States consisted of 27,822 regulars and 114,602 militia. An act of April 22 had authorized the president to call upon the states and territories for men in proportion to their population. A first call was made for 125,000 men, and a month later a second call for 75,000. On April 26 large additions to the regular army were sanctioned for the war The quotas were filled with extraordinary rapidity, and in May 124,776 had volunteered. The troops were concentrated chiefly at Chickamauga, Ga., at Camp Alger, Va., and at Tampa, Fla., which was selected as the point for the embarcation of the expeditionary force for Cuba, and where Maj-Gen. W. R. Shafter was in command. After the arrival of Cervera at Santiago, the blockade of his squadron and the request (June 7) of Admiral Sampson to send a land force for co-operation, the troops embarked on June 7 and 8, but a start was not made until the 14th. On the 19th the fleet of 32 transports arrived off Santiago. The whole force consisted of about 17,000 officers and men, 16 light field guns, a train of heavier pieces, and about 200 vehicles. From the 22nd to the 27th the army was landed at Daiquiri, 18 mi. E. of Santiago, on a rough coast with scarcely any shelter from the sea; after the first day Siboney, 7 mi. nearer Santiago, was used as well as Daiguiri. With the exception of three volunteer regiments (the 1st Volunteer Cavalry, known as the Rough Riders, of which Theodore Roosevelt was lieutenant-colonel; the 2nd Massachusetts and the 71st New York Volunteers), these troops were composed almost wholly of regulars, most of whom had served on the plains against the Indians. Soon afterward more volunteers arrived.

No opposition was made to the landing. The American troops (commanded by Maj.-Gen. Joseph Wheeler until the 29th, when General Shafter landed) pushed forward, but the advance was slow and a week elapsed before Shafter was ready to fight a battle in front of Santiago. Here the defenders, under Gen. Arsenio Linares, held two positions, the hill of San Juan, barring the direct road to Santiago, and the village of El Caney, to the north-ward of the American position of El Pozo. The plan of attack on July 1 was Shafter's, but owing to illness the actual command was exercised by the subordinate generals, Joseph Wheeler, H. W. Lawton and J. F. Kent. General Lawton's division was to attack and capture El Caney, and thence move against the flank and rear of the defenders of San Juan, which would then be attacked in front by Kent and Wheeler from El Pozo. But Lawton for nine hours was checked by the garrison of El Caney, in spite of his great superiority in numbers (4,500 to 520); at 3 P.M. the final assault on El Caney was successfully delivered by Gen. A. R. Chaffee's brigade. Only about 100 of the Spanish garrison escaped to Santiago; about 320 were killed or wounded, including Gen. Vara del Rey, who was killed. In the meantime Wheeler and Kent had an equally stubborn contest opposite San Juan hill, where, in the absence of the assistance of Lawton, the battle soon became a purely frontal-fire fight, and the rifles of the firing line had to prepare the attack unaided. The strong position of the Spaniards, gallantly defended by about 700 men, held out until 12:30, when the whole line of the assailants suddenly advanced, without orders, and carried the crest of the Spanish position. On the American side over 1.500 men out of 15,000 engaged, including several of the senior officers, were kılled or wounded. On the Spanish side, out of the small numbers engaged, more than 50% were out of action. Linares himself was severely wounded

Though victorious, the American army was in danger: after great fatigue under a tropical sun by day, the time spared at night from digging trenches was spent on a rann-soaked ground; the soldiers' blankets and heavy clothing had been cast aside; and there was insufficient food. Brisk firing was continued on July 2 and 3, with a considerable number of casualties to the Americans. On the morning of the 3rd a demand was sent to the Spanish commander to surrender, with the alternative of a bombardment of the city to begin on the 4th.

Naval Battle of Santiago .- On the morning of July 3 Sampson, in his flagship the "New York," left the fleet to confer with General Shafter at Siboney with regard to combined operations at the harbour entrance At 9:31, when he had gone about 5 mi, the "Maria Teresa" was seen coming out. The ships in front of the port were the yacht "Gloucester," the battleships "Indiana, "Oregon." "Iowa" and "Texas," the armoured cruiser "Brooklyn" and the vacht "Vixen." The "Iowa" hoisted the signal "Enemy coming out." All at once stood in toward the Spanish ships, which were standing westward along shore, and began a heavy fire. The "Maria Teresa" (flagship) was followed at 800-yd. intervals by the "Vizcaya," "Colon" and "Oquendo." They were firing vigorously, but most of their projectiles went far beyond the American ships. The "Brooklyn" (flag of Commodore W. S. Schley, the senior officer present) made a turn to starboard, which seems to have caused the "Texas" to stop and back, and to have given the "Colon" the opportunity of passing almost unscathed. "Maria Teresa" and "Oquendo" had taken fire almost at once, and were run ashore about 61 mi, W. of Santiago, burning fiercely. The "Vizcaya" and "Colon" were still standing westward. The "New York," Sampson's flagship, had passed, and stood on signalling the "Iowa" and "Indiana" to go back and watch the port, lest an attack be made on the American transports. The "Vizcaya" hauled down her colours off Aserraderos, 15 nautical miles west of Santiago, and was there run ashore burning. The "Iowa" was ordered to stop and rescue her men, and the "Oregon," "Brooklyn" and "Texas" (and behind them the flagship) settled down to the chase of the "Colon," about 6 mi. ahead. She was, however, slacking her speed, and at 12:40 the "Oregon" opened with her 13-in. guns at a range of 9,000 yds., as did also the "Brooklyn," with her 8-in When the "Oregon" had fired five shells, the "Colon" hauled down her colours, and was beached at the mouth of the Rio Turquino. The whole Spanish fleet was destroyed; Admiral Cervera was taken prisoner. More than 500 Spaniards were killed or wounded, and the survivors (except a few who escaped to Santiago) were prisoners. On the American side only one man was killed and ten were wounded, and no ship received serious injury.

After the naval victory, combined operations were arranged for attacking the batteries of the harbour, but little more fighting occurred, and eventually a preliminary agreement was signed on the 15th, and the besiegers entered Santiago on the 17th. The exposure of the campaign had begun to tell in the sickness of the Americans; yellow fever had broken out to some extent; and no less than 50% were attacked by the milder forms of malarial fever. The army, indeed, was so weakened by illness that the general officers united in urging its removal from Cuba.

Fall of Manila.—On May 7 a telegram had been received from Dewey at Manila: "I control bay completely, and can take city at any time, but I have not sufficient men to hold." Maj-Gen. Wesley Merritt, to whom was assigned the command of the troops for the Philippines, first requested a force of 14,000, and afterward asked for 20,000 men. On May 25 the first troops, 2,491 in number, under Brig.-Gen. T. M. Anderson, sailed from San Francisco. On June 20 possession was taken of the Island of Guam, and on June 30 the ships arrived in Manila bay. A second detachment of troops, 3,586 in number, under Brig.-Gen. F. V. Greene arrived on July 17; on July 25 General Merritt, who had been appointed governor-general, arrived; and on the 31st the five

transports with which he had left San Francisco arrived with 4.847 men, making nearly 11,000 men at Manila, with 5,000 more on the way. General Merritt moved his forces from Cavite, and established an entrenched line within a thousand yards of the Spanish position at Manila On Aug. 7, a joint note from Dewey and Merritt, announcing that bombardment might begin at any time after 48 hours, was sent to the Spanish captain-general, Fermin Jaudenes, who replied that he was surrounded by the insurgents, and that there was no place of refuge for the sick and for the women and children. A second joint note demanding surrender was declined by the Spanish commander. Preparations were made for an attack There were 13,000 troops within the city fortifications, but with the strong fleet in front, and with the beleaguering force of Americans and insurgents ashore, resistance was hopeless. When the combined assault of army and navy was made on the 13th there was no great resistance, and a white flag was hoisted at II o'clock. The total loss of the U.S. during the whole campaign was 20 killed, 105 wounded.

Puerto Rico.-Immediately after the surrender of Santiago (July 17), preparations were made for the invasion of Puerto Rico with 3,500 troops which had been sent as reinforcements to Santiago, but had not landed. They were largely reinforced and left Guantánamo, under Gen Nelson A. Miles, on July 21 The towns on the south side of the island were occupied, practically without resistance. The attitude of the population was friendly, and opposition was not met until advance was begun northward. The troops were divided into four columns, advancing from Guanica around the western end of the island to Mayaguez; from Arrovo at the eastern end to meet the San Juan road at Cayey; from Ponce by the fine military road, 70 mi., to San Juan; and the fourth column by way of Adjuntas and Utuado, midway of the island. The various movements involved several skirmishes On Aug. 12 operations were begun by the "Newark" and other vessels against Manzanillo. But during the night news arrived of the signing of the peace protocol on the 12th, and of an armistice.

The total American loss was—in the navy, I officer, 17 men killed; in the army, 29 officers, 440 men. The health of the American feet was kept remarkably. Its average strength during the I14 days of hostilities was 26,102; the deaths from disease during this time were 56, or at the rate of 7 per 1,000 per year As nearly the whole of the service was in the tropics, and in the summer or wet season, this is a convincing proof of the efficiency in sanitary administration. The army did not fare so well, losing by disease during May, June, July and August, 67 officers and 1,872 men out of an average total of 227,4494. Its larger proportion of illness must of course be ascribed, in part, to its greater hardships. The lack of proper preparation by the war department and the ignorance and thoughtlessness of the volunteers were the principal reasons for the high death rate in the army.

For the terms of the peace and the results of the war see UNITED STATES; PHILIPPINE ISLANDS; CUBA; PORTO RICO.

The literature of the Spanish-American War is voluminous. See the War Notes of the Office of Naval Intelligence, Washington, the appendix to the report of the Bureau of Navigation and reports of other government departments for 1898. F. E. Chadwick's The Spanish-American War (2 vol., 1911) is the standard work. Good histories are H. C. Lodge, The War with Spain (1899); and H. W. Wilson, The Downfall of Spain (1900). See also W. A. M. Goode, With Sampson through the War (1899); J. Wheeler, Santiago Canpaign (1899); Theodore Roosevelt, The Rough Riders (1899); C. D. Sigsbee, Personal Narratives of the Battleship Maine (1899); R. A. Alger, Spanish-American War (1900); Gomez Nuñez, La Guerra hispano-americana (1900); John D. Long, The New American Navy, 2 vol. (1903); and George Dewey, Autobiography (1913).

SPANISH BROOM, a handsome shrub with long switchlike green, few-leaved or leafless branches and large yellow sweet-scented papilionaceous flowers. It is a member of the pea family (Leguminosae), and known botanically as Spartium junceum. It is a native of the Mediterranean region and the Canary Islands, and is often cultivated, especially in California where it blooms almost throughout the year. The whole plant, but especially the flower shoots and seeds, has a bitter taste and tonic and diuretic properties and was formerly used medicinally. The fibres of the young stems were used in making nets, carpets, mats, baskets, etc.;

the flowers yield a vellow dve.

SPANISH LANGUAGE. "Spanish," one of four tongues still spoken in Spain (the others are Catalan, Basque and Galician), is historically Castilian, the speech of Castile Its acceptance as the language of the nation resulted largely from the union of the crowns of Castile and Aragon in 1474 and from the centralizing policy thereafter pursued by Madrid. Discovery and conquest in the New World imposed it as the speech also of the vast territories that once constituted Spanish America, where it is still known as Castilian, and of the Philippines. It is spoken today by about 85,000.000 people.

The Iberian peninsula was linguistically more diversified in the middle ages than it is today. Apart from Arabic in the south and Basque astride the western Pyrenees, there coexisted five major derivatives of Vulgar Latin (Galician-Portuguese, Asturian-Leonese, Castilian, Navarro-Aragonese and Catalan) and a number of lesser dialects. Mozarabic, spoken by Christians living under Moslem sway, was cut off from the trends of linguistic and cultural development to the north and became notably archaic. Castilian, originating in Cantabria (adjoining the Basque frontier) in the early 8th century, soon revealed innovating tendencies consonant with the temperament and enterprise of a people which, shaking off the tutelage of León, in the middle of the 10th century raised the status of its territory from county to kingdom, with Burgos as capital, and found itself thereafter in the van of the reconquest. The taking of Toledo, the ancient capital of Visigothic Spain, in 1085 greatly enhanced the cultural prestige of Castilian and also extended a sway that the next great wave of Christian advance, in the early 13th century, was to carry to the south coast. Thereafter Castilian made steady gains to east and west, reducing Leonese and Navarrese to the status of spoken dialects, and, while not wholly supplanting the other tongues, was from the 16th century generally understood throughout Spain. That same century, which witnessed the incorporation of Portugal in the Spanish dominions, had already seen Castilian recognized as a second tongue there too. More than 600 Portuguese authors are on record as having written in Castilian.

Spanish derives, like the other Romance tongues, from Vulgar Latin, the essentially nonliterary speech of the Roman legionaries and colonists who began the romanization of the peninsula toward the end of the 3rd century B.C. Little is known of the lost "Iberian" tongues or of the extent to which Basque, the one survivor, has evolved from the speech that the Romans found and failed to dislodge. It is on the testimony largely of Basque that tentative prestratum influences are advanced. These include: the substitution of aspirate h for initial Latin f, a development found beyond the peninsula but peculiar, within it, to Castilian; the passage of plosive intervocalic b, d, g to fricative; the pronunciation of s as apico-alveolar and of v as bilabial; the palatalization of nn, ll, ct. The terminations -orro, -arro, -urro are of Basque or Iberian origin, as are the topographical terms vega, nava, páramo; the termination -iego derives from a Celtic or pre-Celtic -aecu. Early Germanic loan words, which number about 800 (plus the ending -engo), are mostly common to Romance, dating from frontier contacts with the Roman empire rather than from the period of Visigothic dominion in the peninsula. The long Moslem occupation bequeathed about 4,000 terms, commonly recognizable by the article prefix al-, many place names and the suffix t. There was a marked influx of French terms in the 12th and 13th centuries, as of Italianisms in the 15th and 16th. The discovery of America introduced many indigenous "Indian" words. The Renaissance also brought about the reintroduction of a spate of Latinisms, mostly abstract terms either lost in the Vulgar Latin of Spain or given a concrete meaning, whence many doublets (artejo and artículo, cadera and cátedra). Later borrowings came chiefly from French (literary and social terms) in the 18th century and from English (politics, sport) in the 19th and 20th. These extraneous elements, promptly assimilated to Spanish speech norms, are predominantly names of things borrowed. In phonology, morphology, syntax and idiom the language remains faithful to its Vulgar Latin origins and all but impervious to foreign influences. By the 18th century Castilian had achieved a stability

in its essential structure that has scarcely altered since. Literary developments dating from the late 19th century greatly enhanced its vigour and flexibility; and today, still respected as the norm throughout the Spanish-speaking world, Castilian has won recognition too as one of the world languages of international diplomacy and administration.

Phonology .- The sonority that is the first characteristic of spoken Castilian derives in part from the voicing of Latin intervocalic surds (apotheca > bodega); in part from a rich intonation extending over more than an octave, its mean falling below that of French or Italian, but chiefly from a yowel-consonant balance that places the language midway between the extreme vocalism of Portuguese and the extreme consonantalism of Catalan. vowels are the basic five, together with a more open e and  $\rho$ . der the accent these latter give ie (earlier ia) and ue (earlier ua, uo), diphthongization being impeded by a following yod (yodh) but not, as in French and Italian, by a closed syllable. Latin internal atonic vowels fell early, proparoxytones thus proclaiming themselves learned forms (ánima for alma, rápido for raudo, -ículo for -ejo). Final e fell after single consonants (cantar, paz); mediaevally there was much apocope too of o and a. Latin diphthongs au, ai, oe, ae gave o, e, e, e; the rejection of Latin hiatus produced new diphthongs (Juan, Santiago) Synaloepha is pronounced, a sequence of up to five or six vowels coalescing in a single syllable ("Y el móvil ácueo a Europa se encamina"). There are no nasal vowels, although nasalization may be induced (mão), and no mixed vowels as in French Unstressed vowels are never relaxed to the point of losing their identity.

Early consonantal changes include, in addition to those already mentioned: the loss of Latin finals, save l, r, s (miel, entre, menos) and, in monosyllables, n (en, con); the reduction of double consonants, save nn, U, rr, to singles (bucca, boca); the passage of initial cl-, fl-, pl- to palatal \(\lambda\) (llave, llama, llano); the palatalizing of guttural plus dental (dixi > dije, restagnare > restañar, factum > hecho) and of ly, ny (palia > paja, vinea > viña); the reduction of c'l, g'l, ly beyond the palatal \( \lambda \) of the rest of the peninsula to ž (oculu > ojo, cilia > ceja); and the advancing of guttural c before a front vowel to prepalatal \$\hat{s}\$ or \$\hat{z}\$, these sounds resulting also from the fusion of ty, cy (platea > plaça, liciu > lizo). A second period of active change in the 16th and early 17th centuries affected chiefly the palatal and dental sibilants, the voiced in each pair (ś, ź; ŝ, ẑ; š, ž) giving way to the voiceless; ŝ then evolved further into the interdental  $\theta$  (taza, dice), and  $\tilde{s}$  into the velar  $\chi$  (Quijote, coger). Voicing may still be induced by assimilation (esmola, hazlo). The h- coming from Latin f- lost its aspirate.

Morphology .- Noun and adjective derive from the Latin accusative, a, as corresponding to the first declension (which largely absorbed the fifth), o, os to the second (and fourth), other endings to the third. Only sporadic survivals remain of the other cases, which are better preserved in the pronoun (ille > él, illi > le, cuius > cuyo). The weakening of ille to the article (el) led to its reinforcing as demonstrative (accu-ille > aquel). neuter survived only in the article (lo bueno) and in the pronoun (esto, ello); neuter noun forms became masculine or feminine according to ending, as pignus > peño(s), pignora > prenda(s). In the verb the Latin third conjugation (-ere) was absorbed by the second (-ére). Traces survive in strong preterites (dije, hice); the present infinitive can be discerned in the far- of haré and the present indicative in vamos, vais. The past participle -udo, common until the 13th century, was discarded thereafter. The adoption for verbs in -er of the preterite and past-participle endings of those in -ir, with the substantial agreement in their tense endings throughout, has largely merged these two conjugations in one. All new verbs, except incipients in -ecer (-escere), are of the first conjugation (telefonear, sintonizar). The degree of preservation of Latin tense endings makes the subject pronoun unnecessary save for emphasis or to distinguish in the third person between Vd. "you" (usted, a contraction of vuestra merced), él and ella; it also contributes to a striking freedom of word order. The use of the "personal a" (before a personal or personified direct object) may be extended to guard against ambiguity ("Al otoño sigue el invierno"

instead of "El invierno sigue el otoño").

Syntax .- The aspects of most interest concern the verb. To the normal evolution of Romance tense values Spanish adds (1) a future subjunctive amare (a fusion of Latin amavero and amaverim), now falling into disuse; and (2) a form amara (Latin amaveram) which may be equivalent to the conditional indicative amaria, to the imperfect subjunctive amase, or (literary) to the pluperfect indicative había amado. From Latin sedere and stare Spanish evolved two words "to be" (ser, estar), connoting greater and lesser degrees of permanence, estar with the present participle gives a continuous tense (estoy viendo). From the 16th century haber became restricted, apart from its use as the impersonal "to be," to the role of auxiliary, tener replacing it as the transitive "to have" Tener is itself one of a number of verbs (quedar, llevar, resultar, etc.) which, employed as semiauxiliaries, add greatly to the flexibility and subtlety of verbal expression. The infinitive may be used as a noun: abstractly in the singular, with subject and object and modified by an adverb; concretely in 'he plural, with an adjective (el trabajar bien, el hacer yo esto, los subires y bajares de la vida). The present participle derives from the Latin gerund (cantando). The subjunctive is used more subjectively than in French, frequently alternating with the indicative to suggest nuances of implication. Constructions with the passive are avoided in favour of active or reflexive (le fusilaron, se le fusiló).

Orthography.—Spanish, if less than the perfect "phonetic" language, shows a close conformity between sound and spelling, I, rr, ch, qu (before front vowels) are single sounds; c is guttural k and (before e, i) interdental \(\theta\) (spelled z before a, o, w); g before e or i is uvular \(\chi\) (also spelled j before any vowel); x may be ks, s or gaz, b, d, g are plosives or fricatives; h is mute. Otherwise sound and symbol agree, and all letters are pronounced. Stress falls normally on the penultimate syllable when the word ends in a vowel, n or s, on the ultimate with other endings. Exceptions bear the acute accent (cámara, cárcel, carrón), which serves also to distinguish the more important of words spelled alike (\(d\)^0 (\(rho^0\)^0, \(d\)^1 (\(rho^0\)^0, \(d\)^1 (\(rho^0\)^0); this acute accent, the tilde of \(\vec{n}\) and the diaeresis of give, gui- are the only diacritics. Exclamation and interrogation marks are written inverted at the beginning as well as normally at the end of interjection or question.

SPANISH LITERATURE. Spanish literature falls into three divisions: Castilian, Catalan and Galician. Galician, for linguistic and historical reasons, is more conveniently dealt with under Portuguese. In the two Senecas, Lucan, Martial and Quintilian—as also in Prudentius—Spain had contributed much to Latin literature before the separation of the Romance languages; while the writings of Spanish Moslems and Jews form an important branch of the literature of Arabic.

## CASTILIAN LITERATURE

By the time of the Moslem invasion (711) the Latin spoken in the Iberian peninsula was already in process of transformation into Romance. By the 10th century, the Glosas emilionenses and the Glosas silenses reveal traces of a vernacular already substantially developed. Mocádem, a blind poet who flourished near

Córdova at the beginning of the century, was recorded 200 years later as having taken "expressions in vulgar Arabic or Romance, called them markaz and built on them his zéjels or muwassahas After 1948 numerous examples of the markaz, or theme stanza. written in a Romance idiom transliterated into Hebrew or Arabic. were recovered from Hebrew and from Arabic muwassahas dating from the 11th century onward. These provided not only the earliest texts in Mozarabic (the Romance dialect of Spaniards living under the Moslems) but also evidence of a popular poetry that may have begun in the time of Mocádem or earlier and can be seen now to explain much in the traditional lyric types (e.g., the villancico) of the later middle ages and the Renaissance. poem as a whole was generally a love song sung by the woman (comparable to the later Galician cantiga de amigo), and the motif in Romance was a cry of passion on which the whole was an elaboration or to which it led up.

Heroic Poetry (11th and 12th Centuries) .- The earliest surviving monument of Spanish literature and one of its most distinctive masterpieces is the Poema de mio Cid, an epic poem (cantar de gesta) of the middle of the 12th century (the existing manuscript is an imperfect copy of 1307). This work of 3,730 irregular lines (from 11 to 18 syllables, with marked caesura and traces of a four-beat accentual rhythm) grouped in assonating laisses tells of the fall from and restoration to royal favour of the Castilian noble Ruy Díaz de Bivar, known by the Arabic title of sids ("lord"), who lived from 1040 to 1099. The historical setting and personages, the topographical detail, the realism of tone and treatment and the proximity in time of the anonymous poet to his hero have allowed the advancing of "historicity" as a first characteristic of the poem and of the Castilian epic in general The latter two of its three cantares, however, while equally convincing in detail, are untrue to recorded history; the conception of the whole is essentially poetic and is handled with much imaginative artistry; and the according of a mere seven lines to the Cid's greatest achievement, the taking of Valencia from the Moslems after a nine-months' siege in 1094, makes clear the subjective scale of values. However, the poem caught the popular imagination and lived on in later epic, chronicle, ballad and drama, helping to fix the popular conception of the Castilian character. The only other surviving epic text (apart from a 100-line fragment of uncertain filiation on Roncesvalles, of the early part of the 13th century) is the wholly fanciful and decadent Cantar de Rodrigo of the 14th century, telling of the Cid's early manhood; it was from this that the later legend of the Cid took shape.

Frequent allusions in the vernacular chronicles to the heroic narratives of minstrels (juglares) make it clear that this mester de juglaría was much richer than the scarcity of surviving manuscripts would suggest. Thanks to the same vernacular chronicles, which from their beginning late in the 13th century accepted these narratives as being of historical validity and prosified them at length in their pages, it has been possible to reconstruct the themes and even, on occasion, fragments of the poetic text of epics on Los siete Infantes de Lara, Fernán González (both set in the 10th century), El Cerco de Zamora (again involving the Cid and perhaps artistically the best) and others. Bernardo del Carpio provides a hero of the days of Roncesvalles in defense of the national prestige against the French Carolingian epic; the remaining themes are an integral part of the feudal history of 10th- and 11th-century Castile, close to the time of telling and less probably related in their origins to the very different French epic than to a remote Visigothic past.

Learned Narrative Poetry (13th and 14th Centuries)—A new school of erudite poetry, much indebted to France and linked not with the itinerant juglar reciting to popular audiences but with the monastery and a literate public, became known as the mester de clerecia. Regularly adopting the French alexandrine in the set mould of the cuaderna via or "fourfold way" (four-line single-rhyme stanza) and dealing with religious, didactic or pseudo-historical matter, it was a product of the study. The school is best and probably first exemplified in Gonzalo de Berceo (d. after 1246), the earliest Spanish poet known to us by name, a cleric of the same San Millán de la Cogolla that had produced the

Glosas emilianenses, in La Rioja. Apologizing for his inadequate Latinity, he versiend unwearynigly in the vernacular the lives of Spanish saints, the miracles of the Virgin and other devotional themes with an ingenuous candour and an accumulation of picturesque and affectionately observed detail which largely atone for his prolixity (about 13,000 lines) and his fidelity to his sources. Also of the 13th century and in the same form are the Libro de Alexandre, much more erudite and pretentious, the Libro de Apolno, a romantic tale of Greek extraction, and the Poema de Pernán Gonçález, a clerical reworking of a lost epic on the 10th-century count of Castile who won his county's independence from León.

The Beginnings of Prose.—A major influence on prose was exercised by Arabic. The gates of oriental learning and story were opened to Spain by the capture from the Moslems of Toledo (1085), which became a centre of translation from oriental languages. In 1120 Pero Alfonso, a Jew converted to Christianity, introduced Indian fable to the non-Arabic reader with his Disciplina clericalis, a collection of tales translated into a barbarous Latin. The translation from the Arabic of the "beast fable" Kailia e Dimma (1251) is the first essay in storytelling in the Spanish language. The romance of the Seven Sages (or Sendebar) was translated under the title of Libro de los engamos e assayamientos de las mageres (1253), and other collections of eastern stories followed.

Alphonso the Wise .- The middle of the 12th century saw the recovery of Córdova, Valencia and Seville by the Christians, the kingdom of Granada alone remaining in Moslem hands. An indication of the more propitious intellectual atmosphere resulting was seen in the founding of the first universities (Palencia c. 1212, Salamanca c. 1243); and under the personal stimulus of Alphonso X of Castile and León (Alfonso el Sabio, "the Wise:" reigned 1252-84) literature achieved official prestige. Alphonso, in whose chancery Castilian replaced Latin as the language for public documents, may be called the father of Castilian prose. He organized a vast enterprise of translation and compilation aimed at fusing in the vernacular all available knowledge, classical, oriental, Hebrew and Christian. The works undertaken, often under his personal editorship, included the great legal code Las siete Partidas (a mine of curious information on the life and customs of the time) and compilations from Arabic sources such as the Libro de saber de astronomía, the Tablas alfonsies, the Lapidario and the Libro de los juegos. With the Primera Crónica general, covering the history of Spain from its first settlers, and the Grande e general Estoria, an attempt at universal history from the creation, Alphonso was the founder of Spanish historiography in the vulgar tongue: the former work, carried by Alphonso to A.D. 711 and completed in the following reign, gave rise to a whole series of chronicles over the following two centuries and was the most influential single work of the Spanish middle ages; the latter work did not reach later than the parents of the Virgin Mary. Himself a poet. Alphonso was responsible too for one of the greatest collections of mediaeval poetry and music, the Cantigas de Santa Maria in Galician (then the accepted vehicle for lyrics).

The 14th Century.—The period of translation and compilation was succeeded by one of brilliant original creation. It is best represented in the prose of Alphonso's nephew the infante Don Juan Manuel (1282-c. 1349) and in the poetry of Juan Ruiz, archpriest of Hita (c. 1283-c. 1350). Juan Manuel's Libro de Patronio, known also as El Conde Lucanor (1335), a collection of 50 tales each pointing a moral, still drew heavily on Arabic sources; but by its individuality of style and treatment, the connecting thread of plot and the relating of fable to the day-to-day problems of life in high position, it ranks high in the beginnings of Spanish fiction. The same author's Libro del caballero e del escudero and Libro de los estados, both betraying indebtedness to the Catalan Raimon Lull (Ramón Llull), likewise pursue in the guise of fiction a doctrinal purpose, the education of a prince.

Earlier, under the influence in part of the matière de Bretagne (see ARTHURIAN LEGEND; TRISTAN), which from the turn of the 13th century had been circulating in Spain in translation, there had appeared (c. 1305) the first Spanish novel of chivalry,

El Caballero Cifar, the work possibly of the archdeacon Fernán Martínez. Cıfar's squire Ribaldo was a distant precursor of Sancho Panza and thus an early token of the constant impinging of the real on the ideal so characteristic of Spanish literature. Contemporary with this was the creation, also related to the Breton cycle, of the Amadis de Gaula (c. 1304-12), destined to father a progeny that held the imagination of kings, courtiers and scholars through the 16th century Sentimental idealism, lyrical atmosphere and supernatural adventure notwithstanding, the weight of evidence is against the traditional ascription to Portugal, where the work is first found mentioned c. 1450; the author may have been a Galician troubadour, João de Lobeira living in exile at the Castilian court.

Juan Ruiz, archpriest of Hita, a man of the people, was the most intensely alert and individualized of early writers. His Libro de buen amor (1330, expanded in 1343) represents a collection of the most disparate elements-Ovid, Aesop, the Pamphilus de amore, the Carmina Burana and the liturgy-with a strong suggestion of Moslem ways of thinking in the mingling of eroticism with devotion and the invitation to the reader to interpret for himself the author's very equivocal teachings But the diversity of adventure was presented as a satiric autobiography and stamped with the author's exuberant personality; and his Trotaconventos, ancestress of Celestina, is the first great character creation in Spanish literature. The dominant metre was still the cuaderna via, handled with a narrative vigour and a plasticity that it had never known before; but the interspersing of the text with lyrics, religious, pastoral-farcical, amorous or satirical, of great metrical variety pointed to the approaching supersession of the "fourfold way."

Continuing evidence of the exotic strands that were being woven into the texture of Spanish letters may be found in the Poema de Yucuf (assigned to the same 14th century) and in the rabbi Sem Tob's Proverbios morales (c. 1355). The former, an Aragonese version in cuaderna via of the story of Joseph, is based not on the Bible but on the Koran and is written in Arabic characters; it is the chief representative of the so-called alianiado ("barbarian") literature, Spanish in language, Arabic (or Hebrew) in tone and script. The Proverbios of Sem Tob (Shem Tobh), comprising 725 alexandrine couplets with internal as well as end rhyme, introduced to Spanish the grave sententiousness of Hebrew poetry with extreme aphoristic concision; his chief sources were the Old Testament, the Talmud and Ibn Gabirol (Avicebron) The principal surviving manuscript, much later than the date of composition, is in Hebrew characters. Sem Tob was a poet too in the Hebrew tongue.

The chancellor Pero López de Ayala (1332–1407) dominates the later part of the 14th century both in poetry, with his Rimado de palacio, the last major relic of the cuaderna via, whose 8,200 lines distilled the essence of a lifetime of experience and disillusion in high places, and in prose as a historian of things seen. His chronicles of the four reigns (the last incomplete) of Peter I. Henry II, John I and Henry III of Castile infused new life in the vernacular into the tradition of the Latin cronicón and greatly stimulated the writing of personal, contemporary history. An early humanist, he translated and imitated Livy and Boccaccio together with Boethius, St. Gregory and St. Isidore.

The 18th Century.—The early part of the 15th century witnessed a first tentative renewal of Spanish poetry under Italian influence, which was to extend and to produce ever deeper effects over the next 150 years. The contrast is strong, during the long reign of John II (1406–54), between the social anarchy of a feudalism in its death throes and the cultivation of politic letters, which was now becoming an expected mark of birth and breeding. Collections such as the Cancionero made for the king c. 1445 by Juan Alfonso de Baena, containing 583 poems by 55 poets ranging from highest nobles to humblest versifiers on the fringes of their service, show not merely the now decadent tradition of the Galician-Portuguese troubadour school but the new stirrings of a much more intellectual poetry which used symbol, allegory and classical allusion in the treatment of themes of high moral, philosophical or political intent. Francisco Imperial, son of a Genoese

settled in Seville, drew on Dante in the first years of the century to present a challenge which Íñigo López de Mendoza, first marqués de Santillana (1398-1458), Juan de Mena (1411-56) and others duly took up. Santillana, like Juan Manuel and Pero López de Ayala, was poet and scholar as well as soldier and statesman, a collector of the masterpieces of foreign literatures and a stimulator of translations. His Prohemio e carta al condestable de Portugal (c. 1449), the earliest work of literary history and criticism in Spanish, draws upon his reading in Italian, French, Catalan, Provençal, Galician and Portuguese as well as in the classics in translation. Imperial had already sought to acclimatize the Italian hendecasyllable. Santillana's 42 sonnets "fechos al itálico mode" marked the beginnings of the formal enrichment of Spanish poetry at the dawn of a new age, though these, like his long poems La Comedieta de Ponza, the Diálogo de Bías contra Fortuna, or La Defunsión de don Enrique de Villena, which in thought and structure likewise show the poet at school in Italy, are today neglected in favour of his charming canciones, decires and serranillas of native inspiration, his role as precursor is still outstanding.

Juan de Mena's vast allegorical poem of the drama of history past, present and to come (El Laberinto de Fortuna, known also as Las Trezientas, c. 1444) was a more conscious attempt to rival Dante; felicitous often in isolated narrative passages out of Spain's herorc past, it is weighed down by pedantry and by over-Latinization of syntax and vocabulary. His metre, the common vehicle of learned poetry throughout the 15th century, is the verso de arte mayor, characterized less by its variable length (9-14 syllables, with 12 as the norm) than by its two hemistichs and strong ternary rhythm; accentual verse will not be found again in Spanish until the 15th century. The other outstanding name in the century's poetry is Jorge Manrique (c. 1440-79), who achieved immortality with one poem, the Coplas a la muerte de su padre.

In prose the age saw the first appearance of books of travel, notably the accounts of a journey to Samarkand (1493-06) of Henry III's ambassador Ruy González de Clavijo (Historia del gran Tamorián) and of the travels in Europe and the near east (1435-39) of Pero Tafur (Andanças e viajes por diversas partes del mundo). Contemporary history took on a biographical dress in two admirable collections of portraits of eminent Castilians, Fernán Pérez de Guzmán's Generaciones e semblanzas (part of a larger Mur de historias, c. 1450) and Hernando del Pulgar's Claros Varones de Castilla (1486).

The Renaissance and the Siglo de Oro.—The unification of Spain under the "Catholic kings" and Columbus' discovery of the New World, following the introduction of printing (1474) and concurrent with the full play of cultural traffic with Italy (where Naples had been since 1443 a dependency of Aragon), may be taken as opening the era of the Renaissance in Spain. With the exception of the more popular veins associated with oral tradition, the mediaeval poetic achievement lapsed into oblivion: the Poema de mio Cid and the corpus of the mester de clerecta were not to be recovered and printed until 1779, the Auto de los reyes magos (sole surviving fragment, from the early 12th century, of mediaeval dramatic activity) not until 1863. National heroic themes survived through ballad and chronicle, early beneficiaries of the printing press.

What conferred on Spanish literature its distinctive mark in this period was, however, the wealth of new experience born of the overseas adventure, reflected not merely in historical and scientific writing but also in the detached and questioning attitude, so strikingly exemplified in the theatre, to the rediscovered norms of classical authority. The first Spanish humanists were also the first grammarians and lexicographers of any Romance tongue: the Gramdstace asstelland (1492) of Antonio de Nebrija (Lebrija) was written under the sense of impending imperial responsibilities. Juan Luis Vives (1492—1540), a figure of European eminence, the brothers Juan and Alfonso de Valdés and others among the best brains and noblest minds of contemporary Spain were friends or followers of Erasmus, whose writings circulated in translation from 1520 until their suppression after his death in 1546, and

whose influence has been seen in St. Ignatius of Loyola, founder of the Society of Jesus, and even, a generation later, in Fray Luis de León

The masterpiece of the early Renaissance is the Tragicomedia de Caluxio y Melibea (c. 1499), a novel in dialogue form by a converted Jew, Fernando de Rojas. The dominant character, a go-between elaborated from Juan Ruiz's Trotaconventos and depicted with a realism unsurpassed in Spanish letters before or since, soon caused the work to be popularly rebaptized La Celestina, thereby obscuring its significance as a tragedy of idealism in the new world of the senses liberated by the Renaissance. The analysis of passion and the dramatic conflict with nemesis that its pursuit involves were worked out with such psychological intensity on the intersecting planes of the noble and the ignoble, of mediaeval and Renaissance, as to make of the work the first indubitable and universal masterpiece of Spanish prose. It gave rise to innumerable sequels and imitations and was in due course translated into most European languages.

Romancero and Early Drama .- Spanish ballads (romances) form the strongest link in a chain of tradition that runs unbroken from mediaeval heroic epic to 20th-century poetry and diama; they lie at the heart of the national consciousness; and their expansion and capacity for survival, from Salonica to Chile, from the Low Countries to North Africa, accurately reflect the farflung boundaries of Spain's prestige in its age of greatness. The ballad form is clear: the 16-syllable line with equal hemistichs (or two octosyllables) and a single assonance, suggesting a regularizing of the old epic versification, though it is doubtful whether we may infer from this that the romancero originated in the fragmentation of the decadent epic. The earliest datable ballads treat of frontier incidents (late 14th century) or lyrical themes (early 15th century), and it has been shown that only 5 out of about 35 "old" ballads on the Cid bear relation to known epic sources, while two-thirds of the whole vast corpus are lyrical in character and betray French or other exotic influence. It is on the ballads on mediaeval heroic themes, nevertheless, that the peculiar importance of the kind in Spain hinges. they formed everyman's source book on national history and on the national character. Circulating first as pliegos sueltos, the traditional ballads were collected in the Cancionero de romances (Antwerp, c. 1550) and in the Silva de varios romances (1550) and thereafter repeatedly. Soon the form was taken up and exploited for lyrical purposes in the romances artísticos of the most famous poets of the age, to remain ever afterward the chosen medium for popular narrative verse.

The origins of drama in Spain may be presumed, in default of evidence, to have been like those of drama in France and England. A tradition of religious performances in the vernacular is supported by references in legal and other documents and by the fragmentary Auto de los reyes magos, already mentioned; and one may infer, as also from a passage in Las siete Partidas, the existence of a secular drama interpreted by juglares. Juan del Encina (1468-c. 1529) marked the first stage in the emancipation of the drama as we know it from ecclesiastical leading strings, by way of performances for a noble patron. The representaciones and églogas in his Cancionero (1496) began as pastoral-religious, cast in a rustic dialect, sayagues, which was later accepted as a convention; but he soon turned to the debating of purely secular themes or to the vividly depicted farce of the Auto del repelón. Three plays dating from a long stay in Italy (Églogas de Fileno y Zambardo, de Cristino y Febea and de Plácida y Vitoriano) show Encina's conception of drama transformed by the experience from an ingenuous mediaevalism to one of bold Renaissance experimenting in the realm of sensuous indulgence, fortified by classical myth and allegory.

Encina's Portuguese disciple Gil Vicente (c. 1465-c. 1536), a court poet at Lisbon who wrote 11 of his 44 plays entirely and 17 of them partly in Spanish, showed a great advance in naturalness of dialogue, acuteness of observation and humour of situation. His weakness lay in plot, his peculiar distinction in a lyricism that expressed itself in the finest Spanish poetry of the period and in a vivid, plastic representation of allegory (as in the trilogy of the Barcas) that looks forward to Calderón. Bartolomé de Torres

Naharro (d. after 1530), who settled at Naples, published there in his Propalladia (1517) six of his eight comedies, all again performed before a noble audience. These show a sense of plot and a first awareness of dramatic theory with the division in form into five acts (soon to be reduced to three) and in kind into comedias a noticia and comedias a funtasia (the former realistic, as the Comedia soldadesca and the Tinellaria, satirizing respectively an army of occupation and the servants' hall in a cardinal's palace; the latter romantic and novelesque, the Comedia serafina and the Himenea being of particular interest as foreshadowing the cloakand-sword comedy with the pundonor or "point of honour" as theme).

The emergence of the drama to the market place and the creation of a public were largely the work of Lope de Rueda (c. 1510–65), who from 1551 toured Spain with his modest troupe, his still more modest properties and a repertoire of his own composing F8s four prose comedies all owned Italian models and were clumsy in construction: it is in the ten comic pass (interludes performed between the acts of longer plays) that his dramatic merit resides, and with it the distinction of fathering the one-act play which, constantly renewing itself, has today some claim to be held the most living and popular of all dramatic forms in Spain.

The first dramatist to realize what might be made of the romancero in the theatre, in the sense of stirring the public's most responsive chord, was Juan de la Cueva (c. 1550-c. 1610): most of his 14 comedies and tragedies (1583) were taken, it is true, from classical antiquity and written in the manner of Seneca, but in three of them (Los siete Infantes de Lara, El Reto de Zamora, La Libertad de España por Bernardo del Carpio) he turned to themes of Spain's early heroic story, already familiar in ballad, and thereby set an example that accounts in large part for the immense fertility of the comedia and for the close accord thenceforth established between dramatist and public. Juan de la Cueva was not an accomplished dramatist, but he helped to found a drama "national" in supject-matter and free from pseudoclassical norms.

The 16th-Century Lyric .- The earlier attempt to Italianize Spanish poetry had failed through an overambitious intellectualizing of theme, on a basis of pedantic imitation, at a time when language and metrics were still incapable of sustaining the burden. A century later Juan Boscán (d. 1542), by reintroducing Italian metres (sonnet, ottava rima, canzone, tercet, blank verse), prepared the way for a much greater poet, his friend Garcilaso de la Vega (1503-36), with whom the lyric was reborn. The importance of the new metres went much beyond the formal. in Garcilaso the most significant novelty is the verse paragraph of the silva (a free combination of hepta- and hendecasyllables), allowing a new concern with the analytical expression of thought and emotion. To a mastery of the poetic process derived from close study of Petrarch, Boccaccio and Sannazaro and also of Theocritus, Virgil, Tibullus and Horace he added the gift of infusing an intense personal note into the most characteristic Renaissance themes. His meagre output of eclogues, elegies and sonnets, published posthumously in 1543, won him recognition for centuries as "the prince of Castilian poets" and largely determined the course of lyric poetry throughout the siglo de oro.

Fray Luis de León (1527-91), adopting chiefly Garcilaso's lira stanza (7, 11, 7, 7, 11) for poems charged with a deep emotional sincerity, typified a so-called "Salamanca school," with its emphasis on content over form. Fernando de Herrera (c. 1534-97) headed a contrasting school of Seville which, deriving equally from Garcilaso, was concerned rather with Petrarchan subtleties of refined sentiment; in a quartet of remarkable odes he gave vibrant expression to heroic themes of the day. A movement of protest in defense of the short native metres, associated chiefly with the name of Cristóbal de Castillejo, was greatly reinforced after 1550 by the printing of romanceros and by the evolving drama which, while employing much metrical variety for the procuring of specific effects, found in the octosyllable the accepted vehicle for narrative and description. Throughout the 17th century poets were to write in both the old and the new, their practice still allowing a notable degree of equation between the old and "verse"

and between the new and "poetry."

For epic poetry the metre was the octava real (ottava rima) and the models Ariosto and Tasso, with the reserve that the themes and the heroes to be sung were those of overseas conquest and expansion or of defense of the empire and of the faith at home. Alonso de Ercilla y Zúñiga came nearest to achievement with his Araucana (1569–90), telling at first-hand of native resistance to the conquest in Chile; its defects sprang from a wavering concept of epic theory, now martial-heroic unrelieved, now amorous-fantastical with admixtures of prophecy and pedantry. Bernardo de Balbuena's Bernardo, on a familiar mediaeval theme, and Lope de Vega Carpio's Dragontea (Drake) and Corona trágica (Mary Stuart) may stand for the multitudinous activity in a kind that laid its compulsion on every poet of ambition.

History.-Prose before the Counter-Reformation produced some notable Lucianesque dialogues, from the pen especially of Alfonso de Valdés (Diálogos de Lactancio y un arcediano and de Mercurio y Carón, both 1528). His brother Juan wrote in Naples a Diálogo de la lengua (c. 1535) which, though not published till 1737, is still a document of the highest critical value. In style these stand at the other extreme from the Relox de principes and the Cartas familiares of Antonio de Guevara (c. 1480-1545), which enjoyed a European notoriety in their day as the Spanish counterpart of euphuism. History in the tradition of Alphonso the Wise continued to be cultivated, patriotism waxing higher as Spain's imperial greatness cast its shadow over Europe; its last great flowering was seen in the Historia de España of Juan de Mariana (c. 1536-1624), the translation of which from its original Latin (1592) into Spanish (1601) by the author himself marked the final triumph of the vernacular for all literary purposes. Diego Hurtado de Mendoza gave in his Guerra de Granada (c. 1572) an extreme example of the concern to write history upon the classical model; the Anales de la corona de Aragón (3562-79) of Jerónimo de Zurita exalted by contrast serious documentation and impartiality over style.

But the real landmarks in historical writing came from the New World and showed the transmuting of vital experience into literature with a vividness till then unknown in Spain. The letters of Columbus, the Cartas de relación of Hernán Cortés and many another narrative by humble conquistadores void of literary artifice or pretension opened up new horizons to the reader and, as in the attempt to capture exotic landscapes in words, enlarged the resources of the language. Most engaging of them all was the Historia verdadera de la conquista de la Nueva España, written in old age by Bernal Díaz del Castillo (1492-c. 1581), who had a phenomenal memory, an infallible eye for the telling detail and a passion for distributive justice. Bartolomé de las Casas (1474-1566), "father of the Indians," wrote history for noble yet partisan purposes: on his Brevisima Relación de la destruyción de las Indias rests a large measure of responsibility for the leyenda negra which Spain's enemies were for so long after to use against it.

Mysticism.-The great period of Spanish mysticism coincided closely with the Counter-Reformation, though it had its antecedents. Raimon Lull had been a notable precursor in 13thcentury Catalonia; and the Dialoghi di amore (1535) of the expatriate Spanish Jew Judas Abrabanel ("León Hebreo"), which both in Italian and in Spanish translation exercised a profound influence on 16th-century Spanish thought, allowed the infiltration of many a Platonic image and doctrine. The literary importance of the mystics derives not only from their subject matter but also from the consideration that in the constant striving to transcend the limitations of language there were liberated resources of expression, especially in the sphere of psychological probing, till then unknown. In the Libro de su vida, in the Libro de las moradas and in the Cartas of the untutored St. Theresa (1515-82) many of the novelist's greatest gifts can be appreciated in embryo. Fray Luis de León, humanist and theologian, did not attain to the highest flights of the mystic ascent, but in his prose De los Nombres de Cristo, as in his poems, he moves by his passionate devotion, his sincerity and his profound feeling for nature, the whole finding expression in a style of singular purity. St. John of the Cross (1542-91) rests on a pre-eminence unparalleled in Spanish literature by virtue of three mystical poems (Noche oscura, Cántico expiritual, Llama de amor viva) of which his prose writings were long and involved expositions The poems throb with religious ectasy and represent the most exalted expression in Spanish of the most exalted of human experiences, mystic union.

The Novel .- Popular taste in the novel was dominated for a century by the monstrous progeny of the Amadis de Gaula, which had achieved print in 1508 These interminable romances kept alive certain ideals of mediaeval chivalry, but, having lost touch with life at every point, represented pure escapism and in due course evoked, along with moral censure, various literary reactions The pastoral novel was one Akın to the ecloque naturalized from Italy by Garcilaso, it was modelled on Sannazaro's Arcadia and inspired by nostalgic echoes of the golden age Its shepherds were courtiers and poets who, no less than the knights-errant, turned their backs on material reality, with the purpose, however, of exploring the more freely, against an idealized and carefree setting, the realm of the emotions. In Spain the first and best example was the Diana (c. 1559) of Jorge de Montemayor; to the vogue it started, Cervantes with his Galatea and Lope de Vega with his Arcadia alike subscribed. In Gaspar Gil Polo's Diana enamorada (1564), which was outstanding among the many sequels and imitations, the story became little more than framework for a lyrical anthology.

A more positive reaction against the inflated tales of chivalric prowess was seen in the picaresque novel (q.v.) initiated in 1554 with the brief, anonymous Lazarillo de Tormes. The word picaro, of doubtful origin, does not appear in the text; the kind, native to Spain, was to exert influence in many foreign literatures. The picaro was the antihero, innocent of ideals and concerned only to keep alive, who lived on his wits and, as he passed from master to master, saw and depicted life from underneath. Important for its part in guiding fiction back to direct observation of life, the picaresque formula had nothing to contribute to the development of the novel as an art form. The seed sown by the Lazarillo did not in fact bear fruit for nearly 50 years; and with the Guzmán de Alfarache (1599) of Mateo Alemán, whose interminable moralizings showed the Counter-Reformation's influence on literature at its heaviest, and Quevedo's Buscón (1626), where realism has become a cynically grotesque caricature of all human values, the kind, though it continued abundant throughout the 17th century, may be held to have given what it had in it to give.

Miguel de Cervantes Saavedra (q.v.; 1547-1616), the culminating figure in his country's literature, produced in Don Quixote (1605-15) the prototype of the modern novel and still its greatest exemplar. Nominally a satire on the already moribund romances of chivalry, the conception allowed of the presentation of reality on two levels, the "poetic truth" of Don Quixote and the "historic truth" of Sancho Panza. In pursuing the constant interaction of these equally valid but rarely compatible attitudes to life Cervantes revealed the true scope of the novel as a philosophical commentary on existence, and in tracing the constant interplay of character between master and squire-in contrast with the static characterization of previous fiction-he established psychology as one of the touchstones of excellence. In the Novelas ejemplares (1613), 12 tales of which the 5 belonging to the romanticadventure type of the Italian novellieri may be discounted, Cervantes particularized his claim to be the first to write novelas (short stories) in Spanish by differentiating between those which interest by the action and those whose merit lies in the mode of telling, "making something out of nothing."

Later Drama.—The comedia achieved its formula and its splendour in the genius of Lope de Vega (1562-1635) toward the close of the 16th century, to fill thereafter with an incredible fertility of invention the 100 years prior to the death of Calderón in 1681. Its manual was Lope's own Arte nuevo de hacer comedias en este tiempo (1600), which firmly rejected the "rules," opted for a mixed kind (comedia is in Spain an all-embracing term) and for metrical variety and made of the vulgo the ultimate arbiter of taste. This was essentially, therefore, a "social" drama, ringing a thousand changes on the accepted foundations of society, respect

for crown. for church and for the human personality, the latter symbolized in the "point of honour" that Lope commended as the best theme of all "since there are none but are strongly moved thereby." The pundonor was in truth a matter largely of convention, "honour" being equivalent, in a very limited and brittle sense, to reputation. Here too the drama was social; characters, to merit esteem, had perforce to abide by all the prescriptions of their fellows. It followed that this was a drama less of character than of action or of intrigue, which rarely if ever grasped the true essence of tragedy or knew the cathartic function. What the great Spanish playwrights did possess was a remarkable sense of stage-craft and the ability to make the most intricate plot grip to the end, however arbitrary the final typing or untying of the knots.

Lope, the "prodigy of nature," as Cervantes called him, who claimed authorship of 1,800 plays, some composed within 24 hours, and of whom we still possess around 500, swept public and fellowdramatists alike into vassalage by his powers of creation. Little that he wrote was perfect, but he had an unerring sense for the theme and the detail that could move an audience, conscious of being on the crest of its country's greatness, to respond to a mirroring on the stage of some of the basic ingredients thereof. Because of him the comedia became a vast sounding board for every chord in the Spaniard's consciousness, a "national" drama in the truest sense. His plays have been classified into religious, mythological, pastoral, novelesque and the like. In reality only two groupings matter: the native historical, and the capa y espada ("cloak-and-sword") plays of contemporary manners. Lope ransacked mediaeval chronicle, the romancero, popular legend and song for heroic themes, chosen for the most part as throwing into relief some aspect of the national character or of that social solidarity on which the Spain of his own day rested. Fuente Ovejuna, Peribáñez y el comendador de Ocaña, El Caballero de Olmedo, La Estrella de Sevilla (concerning the authorship of which there is now some doubt) count among the best.

The cloak-and-sword play, a type which weighed more and more in the comedia after Lope, was pure diversion, written to a number of hollow conventions with much disguising, mistaking of identities, duelling, falling in and out of love and false alarms about "honour" and a duplicating of the plot below stairs between gracioso (the gallant's humorous or would-be humorous lackey) and lady's maid. Though contemporary, it could in no sense be held to give a true picture of society, but it gave pleasure by its infinite resource and dexterity, its sparkling dialogue, its tripping convolutions in the relations between the sexes and its constantly implied paean to the Carpe diem in an irresponsible world. The essentially lyrical character of much of the comedia further explains its charm.

The greatest of Lope's immediate successors was Tirso de Molina, pen name of Fray Gabriel Téllez (c. 1584-1648), whose El Burlador de Sevilla, though far from his best play, achieved fame as presenting the Don Juan legend on the stage for the first time. La Prudencia en la mujer figures among the greatest of Spanish historical dramas, as El Condenado por desconfiado does among theological, while his cloak-and-sword comedies include some of the liveliest of the kind. In the delineation of character, especially feminine character, Tirso had few equals. Juan Ruiz de Alarcón (c. 1581-1639) struck a distinctive note which some have sought to relate to his Mexican birth and upbringing, others to his physical deformity. His 20 plays were sober, studied and imbued with serious moral purpose; La Verdad sospechosa inspired Corneille's Le Menteur. The dramatic conflict between love and honour posed in Las Mocedades del Cid by Guillén de Castro (1569-1631) was the source similarly of Corneille's Le Cid. But moral purpose and dramatic conflict are infrequently to be found among the plays of Antonio Mira de Amescua, Luis Vélez de Guevara, Juan Pérez de Montalbán and the many others who with more or less distinction, if with dwindling originality, bridged the transition from Lope to Calderón.

Culteranismo and Conceptismo.—In poetry and prose the early 17th century was marked by the rise and spread of two interrelated movements. The one, known as culteranismo, of which Luis de Góngora (1561–1627) was the archpriest, resumed, as one of its facets, earlier attempts to ennoble the language by re-Latinizing

it. In Góngora's Soledades and Polifemo y Galatea this process was not only carried to extremes in vocabulary, syntax and word order, so that the reader too must needs be something of a Latinist, but expression was garbed in the full panoply of classical myth and allusion and further complicated by every subtlety of which metaphor is susceptible. Yet this poetry was something other than a deliberate cult of obscurity. Theme and treatment make clear the attempt to achieve a poetry not merely "pure" but timeless, to do for Spanish what the lyric poets of antiquity had done for Greek and Latin, to write poems which, rediscovered after the lapse of hundreds or thousands of years, could be acclaimed still fresh and immortal. Indeed after 300 years Góngora was so rediscovered; but for his age his example invited many who lacked his genius to imitate slavishly his procedures. Gongorism disfigures many a good play by Calderón.

The twin affectation was conceptismo, which played on ideas as culteranismo did on language. The conceptista purveyed thought and sought to shock the reader into attention by the subtlety and also by the violence of his conceits. Aiming always at the semblance of profundity, the quintessential, his style was concise and epigrammatic and demanded for comprehension not the wellstocked mind but one infinitely nimble and alert. Conceptismo thus belonged properly to prose, inclined to satire, since it was much concerned with stripping off appearances, and found its most adequate outlet in the essay. Francisco de Quevedo (1580-1645), the master satirist of his age in the literary, the political and the social sphere and one of Spain's greatest wielders of language, was, in Los Sueños, its outstanding exponent. Baltasar Gracián (1601-58), its preceptist, reduced all its refinements to an exact code in his Agudeza y arte de ingenio, as in a series of treatises (El Héroe, El Discreto, El Oráculo manual y arte de prudencia) he sought to codify also the art of worldly living. Gracián, if doubtfully a philosopher, was a thinker, and his allegorical novel El Criticón, a pessimistic interpretation of life as a "daily dying," was to influence La Rochefoucauld, Schopenhauer and Nietzsche.

Calderón.-Pedro Calderón de la Barca (1600-81) spanned the century of Spain's decline, and his drama constitutes a studied expounding of patterns of behaviour (the pundonor) or of belief. He wrote 80 autos sacramentales (symbolical plays performed on Corpus Christi day), and these, together with La Vida es sueño, La Devoción de la cruz and El Mágico prodigioso, which gave what dramatic tension was possible to a highly intellectualized exposition of Catholic dogma, make of him the perfect literary representative of the Counter-Reformation. In the so-called "honour" plays-El Médico de su honra, A secreto Agravio secreta venganza, El Pintor de su deshonra and El mayor Monstruo los celos—the cold logic with which an unreal code is pursued to the extreme becomes repugnant. El Alcalde de Zalamea, a reworking of a play by Lope, is perhaps his most successful play on the human level. La Vida es sueño, to the extent that it raises profound philosophical issues on a plane of universality, has given him his great fame abroad.

Francisco de Rojas Zorrilla (Del Rey abajo, ninguno) and Agustín de Moreto (El Desdén con el desdén) stand out among those who revolved in the orbit of Calderón. After his death Spanish drama lay dead for the next hundred years. Culteranismo and conceptismo, though symptoms rather than causes, had played their part too in the stifling of imaginative literature, and by the close of the century nothing but the shell remained of the greatness that had been the siglo de oro.

The 18th Century.—With the advent of the Bourbon dynasty in 1700 and its establishment after the War of the Spanish Succession a profound renewal of the country's intellectual life took place. Numerous academies were created, the most influential being the Real Academia Española founded in 1713 to maintain the purity of the language (Diccionario de autoridades, 1726-39; Gramática de la lengua castellana, 1771). Men of letters once again went to school abroad and discovered how far Spain had deviated from the intellectual courses of western Europe.

Moreover, a new spirit of inquiry into the national heritage was to carry back to Luis de León, to Herrera and to Garcilaso an awareness that in the early decades of the century had seemed

limited to Góngora, Quevedo and Calderón (worst of models for an imitative generation) and was indeed to go back earlier still, to unearth the forgotten mediaeval literature. Gregorio Mayáns y Siscar (1600-1781), sometime royal librarian, edited Juan Luis Vives (in Latin), Juan de Valdés and Luis de León and, in a study of Cervantes, initiated Cervantine criticism. The Augustinian Enrique Flórez, embarking on the vast Teatro geográfico-histórico de la iglessa de España better known as España sagrada (29 vol., 1747-73; increased to 52 vol by 1918), helped resurrect the whole cultural background of mediaeval Christian Spain. A landmark of even greater importance was the publication for the first time in Tomás Antonio Sánchez's Poesías castellanas anteriores al siglo XV (1779-90) of the Poema de mio Cid, the works of Gonzalo de Berceo, the Libro de Alexandre and Juan Ruiz's Libro de buen amor. From all this critical activity there resulted a debate between old and new which, waged throughout the middle decades of the century, compelled either side to reason its position and marked the birth of a new critical approach to literature.

Two names stand out: Ignacio de Luzán, educated in Italy and well-grounded in foreign literatures, whose Poética (1737) introduced to Spanish readers the aesthetic of Muratori, Boileau and René Le Bossu and launched the great polemic; and Benito Feijóo (1676-1764), a Benedictine whose Teatro crítico and Cartas eruditas (8 vol. and 5 vol., 1726-60) comprised more than 280 essays ranging over the entire universe of human knowledge. Assailing error, prejudice and superstition wherever he found them and so bitterly assailed in his turn that the king intervened to protect him, Feijóo made a monumental contribution to the intellectual emancipation of Spain Imaginative prose produced the Noches lúgubres of José Cadalso (published posthumously in 1792), looking forward to romanticism; and the Fray Gerundio (1758-68) of Francisco José de Isla, a satire in the guise of biographical fiction on affectation in the pulpit, which looked back to the picaresque novel.

Poetry, moribund for nearly 100 years, raised a timid head at length in a small group at Salamanca, led by the Augustinian Diego González, which toward 1775 turned for inspiration to Luis de León, just as two decades later a group at Seville sought to revive the glories of Herrera; and again, though the lines were now more blurred, Salamanca stood for content, Seville for form. Juan Meléndez Valdés (1754–1817), who learned to think from John Locke and to feel from Edward Young, best exemplified the combination of new influences at work. A conscious artificer rather than a great poet—though the nearest to such among the Salamancans—he helped poetry through the painful apprenticeship necessary to its rehabilitation.

For drama, the second half of the century saw the great battle of the "rules," meaning chiefly the unities that the siglo de oro had spurned. La Raquel (1778) of V. A. García de la Huerta, combining a traditional Spanish theme with neoclassic construction, showed of what the reformist school was capable. The same author's yeat compilation of earlier drama, the ré-vol. Theatro hespañol (1785-86), made apparent in its total omission of Lope, Tirso and Alarcón how unsubstantial were the grounds on which condemnation rested.

It fell to Ramón de La Cruz (1731-94) to bridge the gap, unwittingly but very effectively, by his fecund resurrection on a somewhat ampler scale of the earlier paso or entremés of Lope de Rueda, Cervantes and Luis Quiñones de Benavente (1589-1651). Based on acute satirical, though in the main good-humoured, observation of the contemporary Madrid scene, his one-act sainetes could not, in their brevity, transgress the unities or offend the purist; at the same time they delighted the vulgo and brought the drama back from the realms of pseudoantiquity to the function of commenting on life and society. Leandro Fernández de Moratín (1760-1828) applied the lesson to the full-length play and produced in El Viejo y la niña, La Comedia nueva and El Si de las niñas comedies imbued with deep social seriousness which, written to a meticulous observance of the unities, were still good theatre. The Comedia nueva, a remorseless flaying of such writers as L. F. Comella (1751-1812) who had reduced to absurdity what they fondly believed to be the Calderón tradition, absolves one from any among the best prose of the 18th century.

Romanticism .- The first third of the 10th century proved but a prolongation of the 18th the Napoleonic wars and their long aftermath casting a blight on letters The inspiriting odes of a Nicasio Gallego or a Manuel José Quintana or the impassioned prose of a Gaspar Melchor de Tovellanos, one of the noblest figures of the age (1744-1811), show neoclassic objectivity and proportion set aflame with the emotion of outraged patriotism. War against France did not mean the repudiation of French literary influences. The thousands of liberals driven into exile by Ferdinand VII after 1823 sought refuge for the most part in France (some too in England). Having drunk there the heady wine of romanticism, they flocked back to Spain on Ferdinand's death in 1833.

Such fortuitous contacts were far from being the sole source of Spanish romanticism. The ground for this had been prepared in Cadiz from 1814 in a notable debate on literary values initiated by the German I. N. Böhl de Faber: in Barcelona with the founding in 1823 of the review El Europeo, its three editors a Catalan, an Englishman and an Italian; and in Madrid with Agustín Durán's critical essays on the drama of the siglo de oro and his vast Colección de romances antiguos (1828-31). Romanticism in France, moreover, was largely a revolt against native literary tradition and a turning abroad, notably to Spain, for new sources of inspiration; whereas in Spain it implied the rejection of an alien neoclassicism and to that extent a return to the spirit of its own earlier classics: All the formal characteristics of Spanish romantic drama -the mingling of kinds, the rejection of the unities, metrical variety (this now extended to the inclusion of prose)-had characterized the drama of Lope and his contemporaries, who had moreover treated many of its themes (taken preferably from the Spanish middle ages). It is from a study of these themes that the novelty and significance of the new school becomes apparent. Whereas the drama of the siglo de oro had rested directly on social solidarity, romantic drama was in revolt against society: its protagonist staked everything on his right to be himself, especie única, and, deliberately flouting every convention, defied society to stand in his way. In France, tragedy was by romanticism deflected into drama; in Spain, drama into tragedy,

The movement in Spain, coming to fruition a generation later than elsewhere in Europe, knew a correspondingly short and chequered life. The six plays that epitomize its dramatic achievement fell within the decade 1834-44: Francisco Martínez de la Rosa (1787-1862), La Conjuración de Venecia; Mariano José de Larra (1809-37), Macias; Angel Saavedra, duke de Rivas (1791-1865), Don Álvaro o la fuerza del sino; Antonio García Gutiérrez (1813-84), El Trovador; Eugenio Hartzenbusch (1806-80), Los Amantes de Teruel: José Zorrilla y Moral (1817-93) Don Juan Tenorio; so too the poetry of José de Espronceda (1808-42). Rivas' Don Alvaro came nearest, in the theatre, to expressing a "philosophy" of romanticism; and the preface, from the pen of Antonio Alcalá Galiano, to his Moro expósito to supplying a foundation of precept. But the movement never possessed either the consistency of a school, or a leader, or a corpus of doctrine. Espronceda was the one romantic who lived his romanticism, if with an element of Byronic posturing; his Estudiante de Salamanca, Canciones and unfinished Diablo Mundo were the only subjective lyricism of value that the period produced and marked too a milestone in the enlargement of poetic form. In comparison, the Romances históricos of Rivas and the Cantos del trovador of Zorrilla were little more than exercises, brilliant within the limitations of their kind, in the retelling of picturesque legend. In prose Larra, Rivas, Espronceda and others tried and failed to acclimatize the historical novel after Sir Walter Scott, a form that never struck roots in Spain. Larra, the outstanding prose writer and most critical mind of his generation, dissected society pitilessly in his Articulos de costumbres, which, with the Escenas matritenses (1836-42) of Ramón de Mesonero Romanos and the Escenas andaluzas (1847) of Serafín Estébanez Calderón, helped to prepare the ground for the resuscitation of the novel.

Post-Romantic Poetry.-Three poets bestride the third quarter of the century and, in their diversity, reveal how one of ro-

need to read their handiwork. Moratin's dialogue here ranks manticism's major services was its liberation of the individual personality, whereby literature was set free from compulsory subscription to any school or doctrine. Gustavo Adolfo Bécquer (1836-70), accounted a romantic, was concerned only to give expression to his own tortured emotions. His 76 brief Rimas, which owe something to Heinrich Heine, bear the stamp of a deeply moving sincerity. In his Leyendas Bécquer proved himself too a prose stylist in a richly poetic and imaginative vein. Ramón de Campoamor (1819-1901) affected the epigrammatic in his Doloras, Pequeños poemas and Humoradas, names indicative of a sustained attempt at originality and at bringing poetry back into the realm of ideas. The contemporary fame as a thinker of this bourgeois, utilitarian mind has not withstood the lapse of time; but he had a gift of mildly ironic observation, and later dramatists on occasion found in a quatrain by him matter for a play. Gaspar Núñez de Arce (1834-1903) likewise endowed poetry with a purpose, the social purpose of stimulating the civic virtues and defending the body politic against dangerous heresies. His Gritos del combate represented a noble if despairing attempt, at times overdeclamatory in tone, to stem the tide. Among somewhat later poets were Salvador Rueda (1857-1933; Cuadros de Andalucia, Aires españoles), an exuberant local colourist who has been taken as a precursor of modernism; José María Gabriel y Galán (1870-1905; Castellanas, Extremeñas, Campesinas), a laudator temporis acti singing the traditional virtues of the Castilian countryside; and Rosalía Castro (1837-85), a true poetess of Galicia, whose one volume of poems in Castilian, En las orillas del Sar (1884), invited comparison with Bécquer.

The 19th-Century Novel and Drama,-The last-named poets, each identified with his patria chica, shared with the novelists a quality that was to characterize Spanish fiction on its rebirth. For more than two centuries, from long before the period of afrancesamiento, the kind in which Spain had made its most striking contribution to world literature had been virtually extinct. The revival during the romantic period of the cuadro de costumbres was a pointer to where the native bent lay, and some novelas de costumbres timidly reidentified the novel with realistic social observation. It was Fernán Caballero (pen name of Cecilia, daughter of Böhl de Faber) who, with La Gaviota (1849), determined the particular technique of observation that was to rehabilitate the novel. This simple tale of romantic disillusion captivated less by its plot than by its Andalusian setting and by vividness of colour and detail. Twenty-five years later, coinciding with the restoration of the Bourbon monarchy (1874), came the beginning of the great period of the regional novel.

Pedro Antonio de Alarcón (1833-91), a waverer between the esoteric-romantic and the pedagogic, achieved his masterpiece in El Sombrero de tres picos, a sparkling tale of Andalusian peasant malice. A fellow-Andalusian, Juan Valera (1824-1905), brought much psychological insight and a classical note of cultured detachment to four novels (Pepita Jiménez, Las Ilusiones del doctor Faustino, El Comendador Mendoza and Doña Luz) which depended less on local realism, acutely observed though this was, than on the author's knowledge of men and women. José María de Pereda (1833-1906), graduating through a long series of Escenas montañesas, emerged as the greatest of the school. His realism in depicting his native Santander was no longer merely picturesque but a powerful re-creation of nature as the abiding reality, more important than the individual and therefore than the plot. Sotileza and Peñas arriba, perhaps his best novels, revealed a champion too of traditional values-religion, the family, country life-in a dissolving society typified by the big city.

Emilia Pardo Bazán (1851-1921) attempted, in two novels of Galicia, Los Pazos de Ulloa and La Madre naturaleza, to combine the Spanish Christian outlook with French naturalism, which she had already examined curiously and with many reserves in La Cuestión palpitante. The attempt made clear the incompatibility, and in later novels (La Quimera, La Sirena negra) the return to a genuinely Spanish realism, in which spiritual values also found their place, was complete. Armando Palacio Valdés (1853-1938) was the novelist of Asturias even when, as in the perennially popular La Hermana San Sulpicio, the stage was transferred to

Andalusia or, in La Alegria del capitán Ribot, to Valencia. He likewise experimented, in mid-career and somewhat half-heartedly, with naturalism (La Espuma, La Fe) but was saved by his most engaging quality, humour.

Besides this cult of regionalism, the fecundity in the novel of Benito Pérez Galdós (1843-1920) created a world in itself. Coming to Madrid from the Canary Islands in 1862, Galdós was better placed to see Spain from outside, in the round; and, after living through one of the most turbulent chapters in Spanish history, he addressed himself to the task of imaginatively re-creating its antecedents, beginning with the war against Napoleon. The 46 vol. of his Episodios nacionales, written from 1873 to 1879 and from 1898 to 1912, embraced 70 years of the country's record, from Trafalgar to the early years of Alphonso XII, and taught generations of Spaniards much of whatever history they knew. Other series (Novelas de la primera época, Novelas españolas contemporáneas) completed the revelation of Spain to Spaniards; embodying the author's liberal and challenging views, they constituted a concerted campaign to regenerate and Europeanize Spanish society and thought. Gloria, La Familia de León Roch, Fortunata y Jacinta, Angel Guerra, Misericordia are individual excellences in the rich endowment of this giant among Spanish novelists.

The drama in the later 19th century, disorientated after the brief romantic efflorescence, produced few outstanding works and no clear conception of goal or function. Manuel Tamayo y Baus (1829-98), who began by oscillating between, and even attempting to' fuse, classical tragedy and romantic drama, gradually evolved from verse to prose and from the historical-heroic to the contemporary-social; he achieved fame by the isolated Un Drama nuevo (1867), a powerful portrayal of a Yorick compelled to act on the stage his own personal tragedy. Adelardo López de Ayala (1829-79) used considerable technical gifts to pillory bourgeois vices (El Tejado de vidrio and Consuelo). The Nobel prize for literature (1904) set a seal on José Echegaray (1832-1916), whose 63 plays fall into two main groups: in the first, imbued with a violent neoromanticism, drama became melodrama with a constant striving after effect and a basic falsity of character, passion and situation alike; the second comprised a serious, often tragic drama of social problems in which Ibsen could be seen as one of several foreign influences (El gran Galeoto, O Locura o santidad, De mala Raza, El Hijo de don Juan), though here too passions were apt to be torn to shreds and dénouements to rely on the violent dispatch. Joaquín Dicenta, still close to Echegaray in his search after effect, brought the drama nearer to earth with an unpleasantly realistic study of working-class conditions in Juan José (1805). Failure to master the problems involved in the change of medium robbed Galdós of full success in the theatre, to which he turned increasingly in his concern to stimulate the social conscience (Realidad, La Loca de la casa, Electra, El Abuelo).

The Generation of 1898.—Once again, as in 1700, the turn of the century brought about a radical change in literary values and directions. Over the previous two decades and more a mood of scathing analysis had been developing with the growing conviction that behind the peace and order of a nominally representative regime much rottenness lay concealed. Galdós sensed and gave voice to the disquiet; and it evoked, in Angel Ganivet's Idearium español (1897), one of the most searching analyses of the Spanish character ever written. With 1898 came the brief and disastrous war with the United States, which left Spain stripped of the last vestiges of its trans-Atlantic and Pacific empire. The imperial cycle begun in 1492 had ended in ignominy, and thinking Spaniards embarked on an analysis of their country's ills, a scrutiny of its possible destiny and an attempt to shock the national mentality out of its aboulia. Among literary consequences were the informing of the novel with a new seriousness of purpose and the emergence of the essay-critical, psychological, philosophical-to a new importance. These novelists and essayists constitute the "generation of '98." Rarely in agreement in their diagnosis or on the treatment proposed for the patient, they reinvigorated Spanish letters to a point where these again commanded respect abroad and, as part of the process, laid Spain open to English, French, German, Russian and other influences on a scale never known hafava

Miguel de Unamuno (1864–1936) dominated the literary scene for a generation. In him the national problem was intertwined with his obsession with the personal problem of immortality. The former he studied acutely in his essays En Torno al casticismo and in the Vida de don Quijote y Sancho, the latter in his most important work, Del Sentimiento trágico de la vida. A deliberately provocative rather than systematic thinker, he aimed at sowing spiritual disquiet. The novel was to him an extension of the essay, as the theatre was of the novel, a medium for discussion of the fundamentals of personality, hence stripped of externals and as timeless as the Soledades of Góngora (Niebla, Abel Sánchez, Tres Novelas ejemplares y un prólogo).

) concerned Azorin (pen name of José Martinez Ruiz, 1874himself with the re-interpretation of earlier literary values and of the Spanish countryside (El Alma castellana, La Ruta de don Quijote, Clásicos y modernos). An artist in criticism and a miniaturist of fine sensitivity, he contributed powerfully to the deflation of the hollow rhetoric that had vitiated much of 19th-century writing. José Ortega y Gasset (1883-) brought to the analysis a mind formed in Germany in the study of neo-Kantian thought. From criticism and psychology (Meditaciones del Quijote, El Espectador) he passed to national problems (España invertebrada), then to international (El Tema de nuestro tiempo, La Rebelión de las masas). His Revista de Occidente, founded in 1923 and directed to keeping Spain abreast of contemporary foreign thought, proved a major intellectual force.

) repudiated tradition, religion and the Pío Baroja (1872cult of the individual and sought to be an arch-European, fixing his gaze on the future and making a cult of action for social purposes. The Memorias de un hombre de acción (a series of novels set in the early part of the 19th century) are thus less characteristic than his numerous trilogies on the contemporary scene (La Raza, La Lucha por la vida, Agonías de nuestro tiempo). Insensitive to art for art's sake, Baroja often depresses the reader through his concern to arouse discontent with material conditions; but his novels, full of rude vigour and a fierce independence of spirit, are seedbeds of ideas. There was rude vigour too, together with richness of colour and greater narrative skill, in Vicente Blasco Ibáñez (q.v.; 1867-1927), a survivor into the 20th century of the regional novelist (Flor de mayo, La Barraca, on his native Valencia) who wrote also on contemporary social problems (La Bodega, La Horda) from the standpoint less of the generation of '98 than of the anarchist and who won international renown with novels of World War I (Los cuatro Jinetes del Apocalipsis, Mare nostrum). Ricardo León (1877-1943) was a conscious stylist who sought to recapture the traditional Christian values of a society threatened with materialism (Casta de hidalgos, Alcalá de los Zegries, El Amor de los amores).

The 20th Century.-In Ramón Pérez de Ayala (1881the novel is at once a satisfying art form and a forum for philosophical discussion tinged with Asturian humour. Troteras y danzaderas recaptures something of the vein of Juan Ruiz. Belarmino y Apolonio, a projection of the old debate between faith and reason, makes its characters almost symbolic, as do Tigre Juan and its continuation El Curandero de su honra on the traditional theme of honour. Gabriel Miró (1879-1930) was a lyric poet in prose, with gifts of description and evocation (Figuras de la pasión del Señor, Años y leguas) which retard the action of his novels (La Novela de mi amigo, El Libro de Sigüenza, Nuestro Padre San Daniel) but have given him the reputation of a supreme artist in words. In the work of nearly all these writers can be seen qualities and tendencies incompatible to some extent with the basic art of the novel, which as a kind was already in decline in 1936. The civil war of 1936-39 dealt a heavy blow to imaginative writing in general. Novelists of promise who made their name later were: Camilo José Cela, La Familia de Pascual Duarte (1942); Carmen Laforet, Nada (1944); and Juan Antonio de Zunzunegui. La Quiebra (1947).

The drama also achieved new vigour with the new century under the stimulus of Jacinto Benavente (1866—), another Nobel prize winner (1922) and Spain's greatest playwright since Calderón. With him the drama returned to reality, after the extravagances of Echegaray, by way of social criticism, declamatory verse giving way to prose, melodrama to comedy, formula to experience, impulsive action to dialogue and the play of minds. After a first period of effervescence and irony, Benavente showed a preoccupation with aesthetics as he mastered his medium, and later with ethics. Los Intereses creados, Los Malhechores del bien, La Noche del sábado, La Malguerida are evidence of the extent to which he broadened the scope of the theatre. By contrast, Gregorio Martínez Sierra (1881-1947) remained true to a more traditional Spanish atmosphere, in which idyllic sentiment, though deep-rooted always in Spanish realities, breathed a sensuous joy in nature and in life (Teatro de ensueño, Canción de cuna, El Reino de Dios, Nuestra Esperanza). The brothers Serafín (1871-1938) and Joaquín (1873-1944) Álvarez Quintero, writing as one, were pure costumbristas. If they contributed nothing new to dramatic art, the infinite joie de vivre of their long succession of Andalusian comedies never failed to entertain (La Puebla de las mujeres, El Centenario, La Señora de Alfaqueque). Among other dramatists of note are Manuel Linares Rivas (El Abolengo, 1904, La Garra, 1914) and José López Pinillos ("Pármeno"), author of Esclavitud (1918) and Embrujamiento (1923).

The poetic drama was cultivated with success by Eduardo Marquina (1879—1946), who found inspiration in the heroic past (Las Hijas del Cid, En Flandes se ha puesto el sol); by Jacinto Grau (1877—; El Conde Alarcos, El Hijo pródigo); by Francisco Villaespesa (El Alcázar de las perlas, 1911); by Ramón del Valle-Inclán (Cuento de abril, 1910; Voces de gesta, 1912); and by Luis Fernández Ardavín (La Dama del ermiño, 1921; La Maja, 1928). Federico García Lorca (c. 1898—1936) stands far above any of these. His drama (Bodas de sangre, Yerma, La Casa de Bernarda Alba) was poetic in more than the formal sense, presenting the elemental passions with an intensity that made the characters poetic symbols of man's tragic impotence to arrest his fate.

One other vein of dramatic activity, commonly held to fall below criticism, adds persisting vitality to a long and honourable descent. It is the género chico ("small kind"), heir to earlier paso, entremés and sainete, which within the limitations of the short sketch, frequently with music, achieves a great variety of dramatic effect and for almost a century has charmed the vulgo whose way of life supplies it with setting and theme. Ricardo de la Vega (1839-1910) and Carlos Arniches (1866-1943) span that century between them and are outstanding in the kind, which the brothers Quintero likewise notably enriched.

Rubén Darío, Latin America's greatest poet, brought with him to Spain in 1892 the movement known as modernismo, of which he was the leading exponent. In its ideas modernism was a reaction against 19th-century bourgeois materialism and a search for other and, more specifically, for aesthetic values in life. In literature it was a reaction against naturalism drawing heavily in its poetic norms on French symbolism and parnassianism alike, with elements of a revived romanticism. Endowed with great technical virtuosity, Darío enriched beyond measure the musical resources of Spanish verse, notably in the sphere of rhythm; and under his influence poetry in Spain experienced a renewal comparable only with that effected by Garcilaso almost four centuries earlier.

Though so nearly coincident in time with the movement represented by the "generation of '98," modernism had scarcely any contact with it. Initially it stood for the cult of the ivory tower, wherein the poet took refuge from his fellows and from life and sought self-realization in the pursuit of esoteric beauty. It produced, however, one prose writer, the novelist Ramón del Valle-Inclán (1869-1936), whose four Sonatas typify the four seasons of his hero's life. Valle-Inclán later wrote historical novels (the trilogy La Guerra carlista, the two books of La Rueda ibérica), but here too his vision was purely aesthetic. For the rest, the modernists were poets; and predominantly they were Anadausians, the old contrast still holding between the attraction of form, which interested them, and that of content, with which the northerners of the "generation of '98" were concerned.

Juan Ramón Jiménez (1881- ), beginning to write under the aegis of Darío, soon discovered poetry to be for him not a with-

drawal but the whole of life, reality itself, and his style, initially ornate, became more and more bared, with a turning to blank verse, as he strove to capture the poetic essence of each passing moment. Using and gradually winnowing all the resources of modernism, he became the poets' poet and a powerful influence on the younger generation. The brothers Machado exemplify well the Andalusian-Castilian dichotomy: Manuel (1874-1947), always at heart of his native Seville, was the modernist, with a detached Bohemian attitude to life and the attitude to poetry of the craftsman; Antonio (1875-1939) early lost his heart to Soria, in Old Castile, and his best poetry, written with an infinite simplicity, almost poverty, of artifice, dealt with the recesses of the poet's soul or with the unchanging soul of Castile. Unamuno, Valle-Inclán and Pérez de Avala all figure in the tale of modern poetry, though their poems were but the prolongation in another medium of their prose works. Of the three Unamuno, the least accomplished technically, is the most rewarding as he seeks to distil into verse the intensity of his spiritual striving.

The poetic stature of García Lorca grew steadily after his death in 1936. As in his plays, he is a poet of fundamentals and has shown of what starkness of feeling and effect the copla and romance of secular tradition are still capable. His Romancero gitano (1928) and Poema del cante jondo (1931) reveal the potency of the inspiration that he drew from Andalusian ways and folklore; the former won a wider public throughout the Spanishspeaking world than any other work of poetry of the 20th century. The other major poets of the middle of that century were still those of the pre-civil war generation, contemporaries of García Lorca and heirs, as he was, to Dario and Juan Ramón Jiménez. Pedro Salinas (1892-1951), Jorge Guillén (1893-), Gerardo ), Vicente Alei-Diego (1896-), Dámaso Alonso (1898xandre (1900-), Rafael Alberti (1902-), Luis Cernuda, (1904-) and Manuel Altolaguirre (1906-). The civil war dealt hardly with them too, driving some into exile, stifling the inspiration of others; in the main, their best work was already done. The immediate postwar generation was characterized by its minority groups, fugitive reviews and dispersive tendencies.

minority groups, fugitive reviews and dispersive tendencies.

## CATALAN LITERATURE

Early Poetry.—The Catalan language is properly to be regarded as a branch of Peninsular rather than of southern Gallo-Romance. It shows nonetheless many traces of kinship with Provençal, and the literature in its origins used the langue d'oc and all the poetic forms cultivated by troubadours north of the Pyrenees: Guillem de Bergadá, Hug de Mataplana, Ramon Vidal de Besalú, Guillem de Cervera, Cerverí de Girona were genuine Provençal poets in the same sense as were those of Limousin, Quercy or Auvergne. Ramon Vidal (late 12th-century) was preceptist as well as poet; his Dreita Manera de trobar became the code for Catalan poets writing in a tongue based supposedly on Limoges and known as lemost. This conventional language of poetry was not proof against the contagion of the spoken tongue,

and there resulted a composite idiom well illustrated in Raimon Lull (Ramón Llull, c 1232-1315) who, for all the earnestness of his later religious verse (Lo Desconort, of 69 12-line stanzas in monorhyme, Lo Consili), never wholly divested himself in his poetry of his troubadour beginnings. Ramon Muntaner (1265-1336), writing plain Catalan in prose, is still a troubadour in verse. In the later part of the 14th century, there was apparent a gradual waning of Provençal influence and a turning instead for inspiration to northern France, whence derived a new cult of long narrative poems on novelesque themes, including the matière de Bretagne. With the themes came the metre, known as noves rimades, a sequence of octosyllabic rhymed couplets. There exist poems of this class by Pere March, Guillem de Torroella, Bernat Metge; other poems, anonymous, include the Llibre dels set savis de Roma, of over 3,000 lines, the Facet o Libre de cortesia of half that length, and several which carry the new interest in the langue d'oil even to the incorporation on occasion of passages of French poetry. Another form, the codolada, was native in origin; used also for narrative but more especially for satire, it combined, again in rhyming couplets, an eight-syllable line with a four-syllable one.

The 15th-Century.—The 15th century is the great period of Catalan poetry. It dates from the institution at Barcelona in 1395, under the auspices of John I of Aragon (1387–95), of a "Consistory of the Gay Saber" on the model of that of Toulouse, with "jocs florals" which produced in themselves little poetry of note but typified a new and propitious atmosphere of royal encouragement. This continued under Martin I (1395–1410) and Ferdinand I (1412–16) and contributed much to the emancipation of style from alien influences. As the century advanced, Valencia emerged as a new focus of literary activity; many of the great

names of the age, in prose and verse, were Valencians.

With Joan Berenguer de Masdovelles, Francesc Ferrer, Pere Torroella, Pau de Bellviure, Antoni Vallmanya and, above all, the Petrarchan Jordi de Sant-Jordi and Ausiàs March there developed a school which, as regards versification, is noted for its almost exclusive use of eight-line decasyllabic cobles with crossed or "chained" rhymes and a final four-line tornada and, in inspiration, shows a turning away from France to Italy, where from 1443 an Aragonese court held sway in Naples. The Cants d'amor and Cants de mort of Ausiàs March (1379-1459), the most inspired and profound, if also the most difficult, poet of his age in the peninsula, contain the finest verses ever written in Catalan; they exerted great influence in 16th-century Castile and still do on modern Catalan poets. Very different in class and spirit is the Spill de les dones of Jaume Roig, a bitter and caustic satire upon women of more than 16,000 four-syllable lines which derives a very piquant interest from its really authentic element, the vivid picture of contemporary Valencian life and manners. Joan Roic de Corella is the third great Valencian lyricist, heir to Sant-Jordi and March and perhaps the best representative of the Renaissance spirit, which flowered more fully there than in Barcelona. After this bright period of efflorescence, Catalan poetry faded rapidly, the victim largely of political circumstance. From the union of Aragon with Castile there resulted a predominance of Castilian throughout Spain which inflicted a death blow on Catalan letters. The fact that it was a Catalan, Joan Boscà i Almogàver (in Castilian Juan Boscán), who inaugurated in the Castilian tongue a new school of poetry, and that Castilians regard him as a landmark in the history of their Renaissance muse, is important and revealing; by the year of publication of Boscán's works (1543), Catalan poetry had already been dead for half a century.

Mediaeval Prose.—The earliest prose works in Catalan are later than the poems of the first troubadours of the Provençal school. Though the oldest document dates from c. 1100 (the text of an oath imposed on certain barons by a bishop of Urgel), and the Homilies d'Organyà are attributed to the 11th century, literary prose goes back no further than the close of the 13th. Beginning as history, written close to, and often by prime movers in, the events that it describes, it has the advantage of being entirely original, the language being the true everyday speech found in charters from about the time of James I's accession to the Aragonese throne in 1213. Its four great 14th-century chronicles

are the crowning ornament of mediaeval Catalan prose. Two of them—that of James I, apparently compiled shortly after his death in 1276 with the help of memoirs dictated by himself, and that of Ramon Muntaner (1265–1336), relating at length the expedition of the Catalan company to the Morea and the conquest of Sardinia by James II—are distinguished alike by the artistic skill of their narration and by the quality of their language, inviting comparison with Villehardouin, Joinville and Froissart. Bernat Desclot's chronicle deals particularly with the reign of Peter the Great (1276–85). The account of the reign of Peter the Ceremonious (1336–87) is ascribed to Bernat Descol but was planned and revised by the king himself. The four works collectively present the perfect expression of the spirit and the greatness of mediaeval Catalonia.

Raimon Lull, the Doctor Illuminatus, born in Majorca, stands on an eminence apart through his vast encyclopaedic production, totalling about 180 works in Catalan. Arabic and Latin and covering every branch of mediaeval knowledge and thought. His Libre de contemplació en Déu (1272) marks the beginning of Catalonia's golden age of literature; an exhaustive theological treatise, it is also a mine of information on contemporary society. Blanquerna, his literary masterpiece, is a social-biographical romance which lays the foundations of Catalan fiction. Fèlix de les merauelles del món and the Libre del orde de cauayleria are other doctrinal works with a narrative framework. Inserted in the Blanquerna is the Libre d'amic e amat, a brief masterpiece of mysticism. A century later, Francesc Eximenis (1340-1403) represents something of the same intellectual amplitude, if without the originality or driving force, in Lo Crestià, planned as a comprehensive work in 13 books on theology, morals and politics for the layman but surviving in 4 books which were perhaps the only ones written. From its pages emerges a vivid picture of the mediaeval scene. The Libre de les dones, at once a book of devotion and a manual of domestic economy, is similarly informative on women's way of life at the time.

At the close of the 14th century Bernat Metge inaugurates the so-called "classical age." Well versed in Italian literature, he translated in Valter e Gruselda Boccacio's story of Griselda from the Latin version of Petrarch; in Lo Sommi (1398), a work which clothes scholastic learning with much poetic imagination, he achieved the stylistic masterpiece of Catalan prose. Joanot Martorell's chivalric romance Trant lo Blanc (1460) was notable in its kind for the theme, drawn from Muntaner, of the real adventures of the Catalans in the near east (hence the sparing of it in the famous scrutiny of Don Quixote's library). The anonymous Curial e Güelfa, of the end of the century, draws similarly on Desclot and is the only other Catalan novel in this vein. The beginnings of the drama are represented by the Misteri d'Elcla, a 75th-century Assumption play based on an earlier Representació; sung throughout to traditional music, it is still performed on

Aug. 14 and 15 every year at Elche.

The 16th-18th Centuries .- With the loss of political independence, literary and linguistic independence was lost, and Catalan fell to the level of a patois, kept alive over the next 200 years in the countryside and in the pulpit. The 16th century furnishes a single poet worthy of the name: Pere Serafi, some of whose Cants d'amor (1565), written in imitation of Ausias March but less obscure, are graceful enough to merit remembrance. In prose only scholars, chiefly antiquaries and historians, still wrote in Catalan; such were Miquel Carbonell, compiler of the Chrôniques d'Espanya (1513), Francesc Tarafa (Crònica de cavallers catalans) and Anton Beuter, of whose Cronica general de toda España the first part (dealing with Valencia) appeared in Catalan in 1538. Forty years of research and abundant documentation give interest to the Crònica universal del Principat de Cathalunya of Jeroni Pujadas, of which likewise only the first part (1609) was written in Catalan. Thereafter the eclipse was almost complete. Catalan remained only as the language of folk songs and ballads: in these (collected in the Romancerillo catalán [1853] of M. Milà i Fontanals) it lived on until the reawakening at the beginning of the 19th century.

The Renaixença.—In 1814 appeared the Gramàtica y apologia de la llengua cathalana of Josep Pau Ballot i Torres, a forerunne

of the literary and linguistic renaissance which marked the age of romanticism in Catalonia. The pioneers of the rehabilitation of Catalan for literary purposes soon discovered, however, the inadequacies for the expression of their spiritual and intellectual needs of the ancient tongue that they sought to resurrect. The very popularity of the satirical poems and farces of a Josep Robreño (1780-1838) was a serious obstacle, because of the corruption of the language in which they were written, as was the later advocacy by Frederic Soler (1839-95) of "Catalan as now spoken" in opposition to literary refinement. The development of modern Catalan literature has been directly dependent on the studied enrichment and purifying of the language as a vehicle for contemporary thought; in this the Institut d'Estudis Catalans, founded in Barcelona in 1907, played a notable part. B. C. Aribau's patriotic Oda (1833) and the poems of Joaquim Rubió i Ors (1818-99) and Victor Balaguer (1823-1901) prepared the way, as did the reinstitution in 1859 of the jocs florals, for the imagination and mysticism of Jacint Verdaguer (1845-1902), a great epic poet (L'Atlàntida, Canigó) whose gift is still essentially lyrical. Miquel Costa i Llobera (1854-1922) cultivated with much distinction a classical perfection of form; formal beauty is also the mark of his fellow-Majorcan Joan Alcover (1854-1926). In Joan Maragall (1860-1911) Catalonia found its first truly great modern poet, one who looked forward rather than back and whose poetry is suffused with deep spiritual intent. In this spiritual quality, as also, if less happily, in his theory of inspiration as absolving from the need for perfection of form, he exerted a powerful influence on later poets. Josep Carner (1884- ), Josep-Ma (1886- ) and Josep-Maria de Sagarra (1894-), Josep-Maria López-Picó ) are outstanding names, among many of distinction, in the poetry of the

The foundations of modern Catalan prose were laid by the critical writings of Rubió i Ors, Francesc Pi i Margall, president of the Spanish republic of 1873, and Josep Torras i Bages, archbishop of Vich (La Tradició catalana, 1892). Fiction reached a modest level of achievement late in the century with Josep Pin i Soler (1842–1927), Narcis Oller (1846–1930) and Emili Vilanova (1840–1905). One of the best and most influential writers in prose was the essayist Eugeni d'Ors ("Katonius," 1882—), part of whose Glossari (1906–17) had already been translated into Castilian before the author abandoned Barcelona for Madrid and began himself to write in that tongue. His philosophical novel La ben Plantada is one of the most notable works in modern Catalan literature.

In the theatre Catalan dramatists have produced plays of considerable originality. Angel Guimerà (1847-1924) achieved a European reputation with Terra baixa, which inspired a German and a French opera (Tiefland, La Catalane) and was translated into 12 languages. Beginning with historical tragedy (Gala Placidia, Judith de Welp), Guimerà turned to rural drama in La Boja, to comedy in La Baldirona and La Sala d'espera and to modern tragedy in Martha Rosa and La Festa del blat. The many social dramas of Ignasi Iglésias, inspired originally by the early works of Gerhardt Hauptmann, included one nearly a masterpiece, Els Vells: passing later under the influence of Maeterlinck (Foctollet, Cendres d'amor), he eventually cultivated pure comedy (Girassol). Adrià Gual, author of several works of fantasy, did his best work as director of the Teatre Intim, founded in Barcelona in 1898, which familiarized the public with the great drama of all countries and ages. The painter Santiago Rusiñol achieved repute in the theatre too with a number of vivid and imaginative plays (L'Alegria que passa, La bona Gent, El Mistic).

Hardly had Catalan literature thus won itself once more a place in the sun, when there supervened two calamities, the dictatorship (1923-29) of Primo de Rivera, who banned the use of any language other than Castilian, and the civil war of 1936-39. The expatriation of many intellectuals led to the development of a considerable publishing activity in Catalan in Mexico City and Santiago de Chile.

SPANISH MOSS (Tillandsia usneoides), the name given to a plant of the family Bromeliaceae which hangs in long festoons from the branches of trees in tropical and subtropical American forests, being especially conspicuous on the live oak in the southern United States. The whole plant is covered with scaly hairs for the absorption of water, giving it a grey colour. It is used like horse-hair. From its appearance, which resembles a lichen, it is sometimes called old man's beard.

SPANISH SUCCESSION, WAR OF THE, the name given to the general European war which began in 1701 and ended with the treaties of Utrecht and Rastatt in 1713-14. Its monotonous round of marches and sieges is often quickened by the genius of three great soldiers, Marlborough, Eugene and Villars, while Peterborough and Galway, Catinat and Vendôme, though less highly gifted, were men of unusual and conspicuous ability. As usual in these wars, manoeuvres, threats and feints played the principal part in field warfare. The tangible assets, at the conclusion of peace, the effective seizure of fortresses and provinces was in most cases the principal object with which kings and princes made war. Nevertheless, the object of this war, at least in the case of England and Holland, was less to add a few cities and districts to their own domains than to cripple the power of Louis XIV. The ambition of the Grand Monarque, by placing on the throne of Spain his grandson Philip, had brought into politics the fear not merely of a disturbance but of an entire overthrow of the balance of power. Thus the instrument of Louis's ambition, his magnificent army, was (above all for England) an object in itself and not merely an obstacle to the attainment of other objects. Many of the allies, however, had good reason to fear for their own possessions, and others entered the alliance with at least the hope of acquiring a few material gains at small expense. On the side of the allies therefore, throughout the war, there was a perpetual struggle between offensive activity and defensive passivity. The action of Louis XIV in the matter of the Spanish succession had been foreseen, and William III of England devoted his last years to providing against the emergency by the formation of a coalition to deal with it, and the production of a claimant for the Spanish throne, the archduke Charles. The coalition naturally grew out of the Grand Alliance (see Grand Alli-ANCE, WAR OF THE) and consisted of Austria, some of the German states, Great Britain, Holland, Denmark and Portugal. On the other side Louis XIV was supported by Spain-where Philip, recognized as heir by the dying Charles II, had been promptly installed-Bavaria and Cologne. A doubtful ally was the duke of Savoy, whose policy was to secure and aggrandize himself by adhering at each moment to the stronger party.

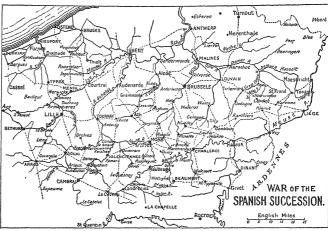

Italy, Chiari 1701 .- The war began, to all intents and purposes, with the handing over of the fortresses in the Spanish Netherlands to the French in March 1701. England and Holland at once began their preparations, but neither state was able to put an army in the field in the year-England because its peacetime army was insignificant, and Holland because it dared not act alone. In Italy, however, the emperor took the initiative, and an Austrian army under Prince Eugene, intended to overrun the Spanish possessions in the peninsula, assembled in Tirol in the early summer. The French army under Catinat blocked the defile of Rivoli, but Eugene reconnoitred passages over the mountains between Roveredo and the Vicenza district in neutral Venetian territory. On May 27, taking infinite precautions as to secrecy and requesting the Venetian authorities to offer no opposition so long as his troops behaved well, Eugene began his march by paths that no army had used since Charles V's time, and on the 28th his army was on the plains. Catinat was surprised, for he had counted upon Venetian neutrality, and when, in the search for a passage over the lower Adige, Eugene's army spread to Legnago

and beyond, he made the mistake of supposing that the Austrians intended to invade the Spanish possessions south of the Po. He thinned out his line to cover all the front as far as that river. But Eugene found an unguarded spot. With the usual precautions of secrecy (deceiving even his own army), he crossed the lower Adige in the night of July 8-9. Catinat at once concentrated his scattered army backward on the Mincio. while Eugene turned northward and regained touch with his old line of supply, Roveredo-Rivoli. For some time Eugene was in great difficulties for supplies, as the Venetians would not allow his barges to descend the Adige. At last, however, he made his preparations to cross the Mincio close to Peschiera and well beyond Catinat's left. This was executed on July 28 and Catinat fell back quietly to the Oglio. But his army resented his retreat before the much smaller force of the

Austrians and, early in August, his rival Tessé reported this to Paris, whereupon Marshal Villeroy, a favourite of Louis, was sent to take command. The new commander was the least competent of all the French senior officers. Before long he attacked Eugene in a well entrenched position at Chiari (Sept. 1) and was thoroughly defeated. In the winter a fresh mishap befell the French. Eugene surprised Cremona on the night of Feb. 1, 1702, and, after a confused fight, drew off, taking with him Villeroy as a prisoner. The rest of the French army retreated, while Eugene quietly resumed his winter quarters and his blockade of Mantua.

Marlborough's First Campaign .- With the year 1702 the real struggle began. Villars and one or two others of Louis's counsellors urged the king to concentrate his attention on the Rhine and the Danube, where, they pointed out, was the centre of gravity of the coalition. This advice was disregarded, and with political aims, the largest French army was employed on the side of the Meuse, while the Rhine front was entrusted to smaller forces acting on the defensive. In Italy the balance of power remained unchanged, except that one of Louis's best generals, Vendôme, was sent to replace the captured Villeroy. In the Low Countries, Ginkel, earl of Athlone, the interim commander of the allies (English, Dutch and minor German states), was at the outset outmanoeuvred by the French (Boufflers), and the momentary threat of a French invasion had a lasting effect on the Dutch authorities, whose timidity thereafter repeatedly ruined the bestlaid schemes of Marlborough, who was obliged to submit to their obstruction and their veto. This handicap, moreover, was not the only one under which Marlborough suffered. Unless it is realized and borne in mind that the great captain was struggling against factiousness and intrigue in England and against jealousies, faintheartedness and disagreements among the states who lent their contingents to his miscellaneous army, the measure of his achievements in ten years seems small. But in fact it was marvellous. Under 18th-century conditions of warfare, and with an army so composed that probably no other man in Europe could have held it together at all, obstructed and thwarted at every turn, he yet brought Louis XIV and France to the very edge of ruin.

In this theatre of war the French, in concert with the garrisons of the Spanish Netherlands, had fortified a line of defense more than 70 mi. long from Antwerp to Huy, as well as another line, longer but of only potential importance, from Antwerp along the Scheldt-Lys to Aire in France. Beside the "lines of Brabant" Boufflers held all the Meuse fortresses below Huy except Maestricht. Marlborough concentrated 60,000 men (of whom 12,000

DRAWN BY BARTHOLOMEW & SONS, LTD , EDINBURGH

only were British) about Nijmwegen in June, and early in July, having made his preparations, he advanced directly by Harnont on Diest. Boufflers hastily fell back, in order to regain the Brabant lines. Marlborough, with the positive object of bringing his opponent to battle at a disadvantage, won the race and awaited the arrival of Boufflers's tired army to strike it a paralyzing blow. But at the critical moment the Dutch deputies forbade the battle, content to see the army that had threatened Holland with invasion driven off to a safe distance without bloodshed (July 22). After this experience Marlborough thought it prudent to pacify the Dutch by besieging the Meuse fortresses. several of which fell in rapid succession (Sept.—Oct.). Boufflers fell back within the defended area of the lines of Brabant, and the campaign closed with the capture of Liège by the allies (Oct. 12). Marlborough was created a duke on his return to England in November.

**Friedlingen.**—On the Rhine the campaign was, except for two disconnected episodes, quite uneventful. The Imperialists under a methodical general, the margrave Louis of Baden, gathered in the Neckar country and crossed the Rhine above Speyer. Catinat, now old and worn out, was sent to Strasbourg to oppose the threatened invasion of Alsace, and, like MacMahon in 1870, he dared not assemble his whole force either on the Lauter or on the Ill. The margrave invested Landau (July 29) and with a covering army occupied the lines of the Lauter about Weissenburg, which Catinat did not attack. Hence Landau, valiantly defended by Melac, had to be surrendered on Sept. 12. But at the same time the elector of Bavaria took the side of France, surprised Ulm, and declared a local war on the house of Austria and the "circles" of Swabia and Franconia. The margrave then, in order to defend his own country, hurried to Kehl with the greater part of his army, leaving a garrison in Landau and a corps of observation on the Lauter. To co-operate with the elector, Catinat had made up a corps out of every available battalion and squadron and placed it under Lieutenant-General Villars. This corps drew away into Upper Alsace and the margrave followed suit until the two armies faced one another on opposite sides of the Rhine near Huningue. Villars crossed the Rhine and won the first victory of his brilliant career at Friedlingen (opposite Huningue). Soon afterward he placed his army in winter quarters in Alsace, and Louis of Baden disposed his troops in two entrenched camps opposite Breisach and Strasbourg respectively. In Italy Vendôme, superior in numbers but handicapped by instructions from Versailles and by the necessity of looking to the Italian interests of King Philip, gained a few minor successes over Eugene.

In the next two years Bavaria was the centre of gravity of the French operations, and only campaigns of the methodical and non-committal kind were planned for Italy and the Low Countries. In this year began the Camisard insurrection, in the Cevennes, which necessitated the detachment of a considerable body of troops from Vendôme's army in Italy.

In the Netherlands the French field army was behind the lines of Brabant, the Spanish troops in the lines of Flanders (Antwerp-Ghent-Aire). Together the two considerably outnumbered Marlborough (90,000 against 50,000), but the duke managed to be first in the field. After capturing Bonn in May, Marlborough's plan was to break the immensely long line of defence of the French and Spaniards by the capture of Antwerp. One Dutch corps under Coehoorn was to assemble in the Sluvs-Hulst region, and another under Opdam at Bergen-op-Zoom while Marlborough, after manoeuvring Villerov's field army out of the way, was to join them before the fortress. Marlborough executed his own share of the movement with his usual skill, but the Dutch generals enabled the French to emerge from the manoeuvre with a handsome victory. Great projects were now entertained by the French, nothing less than the capture of Vienna by a Franco-Bavarian-Hungarian army being the intention. The elector of Bavaria insisted that Villars should cross the Black Forest and join him, which Villars was unwilling to do thus early in the year, as two-thirds of his officers were as usual on leave or detached on recruiting duties. Courtier though he was, the marshal would not stir even in spite of the king's orders until he was ready. At the end of April, leaving Tallard alone to defend Alsace against the margrave of Baden, Villars plunged into the defiles of the Black Forest and on May 8 joined the elector at Ebingen. All seemed favourable for the advance on Vienna, but at the last moment the elector half repented of his alliance with the enemies of Germany and proposed instead a junction with Vendôme in Italy by way of Tirol. This proposal came to nothing, the Tirolese were soon roused to revolt by the misconduct of the ill-disciplined Bavarians, and Vendôme, who, like Luxembourg, was a giant in battle and a sluggard in camp, would not stir.

Hochstett, 1703.-Villars had posted a protective force at Ulm to contain the Margrave's army should it turn back upon him, and this, after an engagement at Munderkingen (July 31) induced the cautious Louis to return to the Rhine. Five weeks later, however, the Margrave returned in full force, and moving by the right bank of the Danube reached Augsburg on Sept. 6. The elector, returning from his futile Tirol expedition, had already rejoined Villars at Dillingen, and the marshal persuaded him to attack the Austrian army that covered Vienna before the two imperial generals could join forces. The result was the battle of Hochstett (Sept. 20) in which the elector and Villars won a great victory, at a loss of only 1,000 men to the enemy's 11,000. Rarely indeed had an 18thcentury general so great an opportunity of finishing a war at one blow. But even Villars saw no better use for the victory than the unimpeded junction of his own army and Tallard's and winter quarters in Württemberg. But Tallard remained on the Rhine, and Villars in disgust applied to be recalled. The Margrave, entrenched as usual, kept the field for another month and then retired to the Lake of Constance, where, in a still unexhausted district, he spent the winter. Tallard meanwhile invested Landau which surrendered on Nov. 12. Old Breisach, besieged by Vauban, capitulated on Sept. 6. Thus in Germany, though the grand advance on Vienna had come to nothing, the French had won important successes and established an army in Bavaria. In Italy, on the other hand, Vendôme, although no longer opposed by Eugene, achieved nothing,

Rhine and Danube Campaign, 1704.-The campaign of 1704, though in the Low Countries and in Italy practically nothing was done, is memorable for what was perhaps the greatest strategical operation in the 18th century, Marlborough's march to the Danube. At the outset the elector and Marsin (Villars' successor) were on the Iller, between Ulm and Memmingen, Tallard between Strasbourg and Landau, Villeroy as usual between the Brabant lines and the Meuse. On the other side the Margrave Louis was in the Stockach-Engen region. Responsible for guarding

the whole of the Middle Rhine as well as for opposing the elector he was weak everywhere, and his defence of the Rhine was practically limited to holding the "lines of Stollhofen," a defensive position near Buhl in Baden. With Breisach and Kehl in their own hands, the French were more or less closely in touch with their comrades in Bavaria, and Tallard convoyed a large body of recruits for Marsin's army through the Black Forest defiles. But in doing so he lost most of them by desertion, the Margrave's army dogged his march, and in fact no regular line of communication was established. Marlborough's purpose at any rate was quite definite-to transfer a large corps from the Low Countries to Bayaria and there in concert with the allies in that quarter to crush the elector decisively, but rather than be burdened with Dutch counsellors he chose to forgo the assistance of the Dutch troops. These were left under Overkirk to defend the Meuse, and English and English-paid troops alone took part in the venture

Mariborough's March to the Danube.-Marlborough calculated that as he progressed up the Rhine the French would collect to prevent his crossing, instead of themselves passing over to join the elector and Marsin. Thus the expedition would reach the Neckar mouth, without its true purpose being suspected, and once there Marlborough would vanish from the ken of the defenders of the Rhine, to reappear on the Danube where he was least expected. On May 12 the army crossed the Meuse at Ruremond, on the 23rd it reached Bonn, on the 29th Mainz. On June 1 the puzzled French noted preparations for bridging the Rhine at Philipsburg. But two days later the English had turned to their left into the valley of the Neckar. On June 10 Prince Eugene and on the 13th the Margrave appeared at the duke's headquarters to concert operations. It was arranged that the margrave was to join Marlborough and that Eugene should command the Stollhofen and other forces on the Rhine, for Tallard, it seemed, was about to be joined by Villeroy1 and Marlborough knew that these marshals must be kept west of the Rhine for the six weeks he allowed himself for the Bavarian enterprise. The Margrave's army duly joined Marlborough's on June 22 at Ursprung, 12 m. north of Ulm, where the elector and Marsin were encamped. The endurance of Marlborough's corps, as displayed in the long march from Ruremond, was not the least extraordinary feature of the operation. For 18thcentury troops such performances were generally provocative of desertion, and involved the ruin of the army that attempted it. But Prince Eugene, we are told, was astonished at the fine condition of the army. On the French side meantime all was perplexity, and it was not until a week after the Margrave and Marlborough had joined, that Villeroy's main body from the Meuse started for Alsace to watch Eugene's corps, or rather the Stollhofen-Buhl position. This meant conceding both the initiative and the superiority in numbers to Marlborough,

Campaign on the Danube, 1704 .- The duke had now manoeuvred himself with brilliant success from one theatre of war to another, and had secured every advantage to himself. From before Ulm he sidled gradually along the north side of the Danube in the hope of finding an unguarded passage. He and the Margrave exercised the general command on alternate days, and when on his own day he arrived opposite Donauwörth, knowing Louis's caution, he thought that direct attack was better than another two days' extension to the east. Moreover he needed a walled town to serve as a magazine. In the late afternoon of July 2 the army was flung, regardless of losses, against the entrenched hill of the Schellenberg at Donauworth, where the elector had posted a strong detachment. The attack cost 6,000 men, but it was successful, and of the 12.000 Bavarians on the hill only 3,000 returned to their main body, which had now moved from Ulm to Lauingen. Passing the river, the allies besieged and took the small fortress of Rain, and thence moved to the neighbourhood of Augsburg, thoroughly and deliberately devastating the countryside so as to force the elector to make terms. The best that can be said of this barbarous device, is that Louis XIV had several times practised it. Its most effective condemnation is that military devastations, in these purely political contests, were entirely

<sup>1</sup>Even Villeroy it appears rose to the situation thus far, but the king only allowed him to send 25,000 men to Tallard.

unprofitable. Louis had already found them so, and had given up the practice. In the present case Mariborough's own supplies ran short, and his convoys were harassed. The movements of the two armies were but trifling. Mariborough, though superior, was not decisively superior, and his opponents, well entrenched near Augsburg, waited for Tallard and (in vain) for Villeroy. Mariborough marked time until Eugene should join him.

There were now five armies in the field, two allied and three French. The centre of gravity was therefore in Villeroy's camp. If that marshal followed Tallard, even Eugene's junction with Marlborough would not give the latter enough force. If Tallard alone joined the elector and Eugene Marlborough, the game was in the hands of the allies. But none of the possible combinations of two armies against one were attempted by either side. Eugene when informed that Tallard was on the move slipped away from Villeroy to join Marlborough. Tallard and the elector, aware of Eugene's march, were content to join forces peaceably at Augsburg. Villeroy, in whose hands was the key of the situation, hesitated and finally tried in vain to detain Eugene (who was already far away) in the Stollhofen lines. The last stage of the campaign was brief. Marlborough and Eugene had in mind a battle, Tallard and Marsin a war of manoeuvre to occupy the few weeks now to be spun out before winter quarters were due. The two allied armies met in the Danube valley on Aug. 6. If the enemy remained on the south side Eugene was to cross, if they recrossed to the north bank Marlborough was to follow suit. The margrave Louis of Baden had been sent off to besiege Ingolstadt as soon as Eugene had come within a safe distance. When therefore the French and Bayarians were reported opposite Eugene on the north side, Marlborough crossed at once, and without waiting for the margrave the two great soldiers went forward. On Aug. 2 (see Blenheim) they attacked and practically destroyed the armies of Tallard, Marsin and the elector.

Campaign of 1705.—The campaign of 1705 was uneventful and of little profit to either side. Marlborough's army had returned to the Low Countries. Villeroy had also returned to Brabant and retaken Huy. With him was the now exiled elector of Bavaria. On July 18, after a series of skilful manoeuvres, Marlborough forced the lines of Brabant at Elissem near Tirlemont, but not even the glory of Blenheim could induce the Dutch deputies to give him a free hand, or the Dutch generals to fall in with his schemes. King Louis was thus able to reinforce Villeroy betimes from Villars's Lorraine army, and the campaign closed with no better work than the razing of the captured French entrenchments. On the Rhine Villars, with a force reduced to impotence, carried on a spiritless campaign against the Margrave Louis. In Italy there was serious fighting. Here Vendôme's army engaged in the attempt to subdue Victor Amadeus of Savoy and was so far successful that the duke implored the emperor for aid. Eugene was sent with new reinforcements, opposed to which was a force under Vendôme's brother Philippe, called the Grand Prior. This man, a lazy dilettante, let himself be surprised by Eugene's fierce attack on the line of the Adda. The day was restored however, and the Austrians beaten off, thanks to Vendôme's opportune arrival and dauntless courage (battle of Cassano, August 16). Nevertheless, the subjugation of Piedmont was put off until the next year

Ramillies, 1706—1706 was a bad year for the French. At the very outset of the campaign in the Netherlands, Villercy, hearing that some of the allied contingents that composed Marlborough's army had refused to join, ventured out from his new defensive lines along the Dyle and moved towards Namur. Marlborough hurried forward to intercept him before he could reach the shelter of the Meuse fortresses and was able (May 12) not only to win but also to profit by the glorious victory of Ramillies (q.v.) on the 12th of May.

In Italy the campaign had, as before, two branches, the contest for Piedmont and the contest between the French forces in Lombardy and the Austrian second army that sought to join Victor Amadeus and Starhemberg. The latter, repulsed by Vendôme at Cassano, had retired to Brescia and Lake Garda, Vendôme followed, and in April 1706, profiting by Eugene's temporary absence,

completely (battle of Calcinato, April 19), and he hustled the fragments of the Imperialist army back into the mountains, where Eugene had the greatest difficulty in rallying them. Until the middle of June Vendôme completely baffled all attempts of Eugene to slip past him into Piedmont. He was then, however, recalled to supersede Villeroy in Belgium, and his feeble successor entirely failed to rise to the occasion. Philip of Orleans, with Marsin, was besieging Turin. As soon as he knew of Vendôme's departure Prince Eugene emerged afresh from the mountains, and, out-manoeuvring the French in Lombardy, hurried towards Turin. Victor Amadeus, leaving the defence to the Austrian and Piedmontese infantry, escaped through the besiegers' lines and joined his cousin with a large force of cavalry. On Sept. 7 they attacked the French lines round Turin. Owing to the disagreements of their generals, the various corps of the defenders, though superior in total numbers, were beaten in detail. Marsin was killed and Orleans retreated ignominiously to Pinerolo. The battle of Turin practically ended the war in Italy.

Both in the north and in the south the tide had now receded to the frontiers of France itself. But it is from this very point that the French operations cease (though only gradually it is true) to be the ill-defined and badly-joined patchwork of forays and cordons that they had hitherto been. In the place of Tallards, Marsins and Villeroys Louis made up his mind to put his Villars, Vendômes and Berwicks, and above all the approach of the allied armies roused in the French nation itself a spirit of national defence which bears at least a faint resemblance to the great uprisings of 1792. For the gathering of this unexpected moral force 1707 afforded a year of respite. Marshal Tessé formed a strong army for the defence of the Alpine frontier. In Germany Villars not only pricked the bubble reputation of the lines of Stollhofen, but raided into Bavaria, penetrating as far as Blenheim battlefield before he gave up the attempt to rouse the Bavarians again. The Imperialists and Piedmontese in the south succeeded in turning the Alpine barrier, but they were brought to a complete standstill by Tesse's gallant defence of Toulon (August) and finally retired over the mountains. In Belgium the elector of Bavaria, who was viceroy there for King Philip, and was seconded by Vendôme, remained quiescent about Mons and Gembloux, while Marlborough, paralysed more completely than ever before by the Dutch, spent the summer inactive in camp on the Gheete.

Campaign of 1708.—In 1708 Eugene foresaw this shift of the centre of gravity and arranged with Marlborough to transfer his army which was ostensibly destined for the Rhine campaign to Brabant, since the French was markedly superior in numbers to Marlborough's and hardly inferior to Marlborough's and Eugene's combined. King Louis had put his young grandson and heir, the duke of Burgundy, at the head of the great army which assembled at Valenciennes, and gave him Vendôme as mentor. But the prince was pious, mild-mannered, unambitious of military But the prince was pious, mid-mannered, unamous glory and also obstinate, and to unite him with the fiery, looseliving and daring Vendôme, was, as Saint-Simon says, "mixing fire and water." At the end of May Vendôme advanced to engage Marlborough before Eugene should join him. As the French came on towards Brussels, Marlborough, who had concentrated at Hal, fell back by a forced march to Louvain. Vendôme having thus won the first move, there was a pause and then the French suddenly swung round to the west, and began to overrun Flanders, where their agents had already won over many of the officials who had been installed by the allies since 1706. Ghent and Bruges surrendered at once, and to regain for King Philip all the country west of the Scheldt it only remained to take Oudenarde. On the day of the surrender of Ghent Marlborough was moving to interpose himself between the French and their frontier, and one long forced march brought his army almost within striking distance of the enemy. But though Eugene himself had joined him, Eugene's army was still far behind. Vendôme soon moved on Oudenarde. But scarcely had he begun this investment when Marlborough was upon him.

Oudenarde.—The duke discussed the situation with Eugene.

Mariborough was half inclined to wait for Eugene's troops, for time, had only enough energy remaining to take Mons before he he knew that Vendôme was no ordinary opponent, but Eugene counselled immediate action lest the French should escape, and relying on his own skill and on the well-known disunion in the French headquarters, Marlborough went forward. As he approached, the enemy gave up the siege of Oudenarde and took up a position at Gavie, 7 m. lower down the Scheldt. Here the dissensions in the French headquarters became flagrant. Vendôme began to place part of the army in position along the river while the duke of Burgundy was posting the rest much farther back as another line of defence. The allied main body, marching with all speed, crossed the Scheldt at all hazards. In the encounterbattle which followed (see Oudenarde) Marlborough separated, cut off and destroyed the French right wing. The French retreated in disorder on Ghent (July 11) with a loss of 15,000 men. Marlborough was prevented from carrying out his desire for a prompt move on Paris after Oudenarde. For the moment Berwick, recalled from Alsace, manoeuvred about Douay, while Vendôme remained near Ghent, and between them Marlborough's and Eugene's armies devoted themselves to the siege of Lille. In this town, one of Vauban's masterpieces of fortification, the old Marshal Boufflers had undertaken the defence, and it offered a long and unusually gallant resistance to Eugene's army. Marlborough covered the siege. The French generals limited their efforts first to attempting to intercept a huge convoy of artillery and stores that the allies brought up from Brussels for the siege. and secondly to destroy another convoy that was brought up from Ostend by the General Webb known to readers of Esmond. The futile attack upon the second convoy is known as the action of Wynendael (Sept. 28).

On Dec. 8 the brave old marshal surrendered, Eugene complimenting him by allowing him to dictate the terms of capitulation. Ghent and Bruges were retaken by the allies without difficulty, and, to add to the disasters of Oudenarde and Lille, a terrible winter almost completed the ruin of France. In despair Louis negotiated for peace, but the coalition offered such hard terms that not only the king, but his people also, resolved to fight to the end.

1709, Malplaquet.-When spring came round Marlborough proposed to make a daring thrust toward Paris, masking the fortresses, but this scheme was too bold even for Eugene, who preferred to reduce the strong places before going on. Lille having been successfully besieged, Tournai was the next objective, and the allies suddenly and secretly left their camps before Lille as if for an attack on the Douai lines (June 26-27). But before noon on the 27th they had invested Tournai. A few days afterwards their siege guns came up from Menin by water (down the Lys and up the Scheldt) and the siege was pressed with intense vigour. But it was Sept. 3 before the citadel capitulated. Then Marlborough, free to move again, transferred his army secretly and by degrees to the river Haine, and burst through the French lines almost unopposed. Mons was weakly held, and Marlborough hoped by the rapidity of his operations to take it before Villars could interrupt him. But Villars also moved quickly, and his eager army was roused to enthusiasm by the arrival of Boufflers, who, senior as he was to Villars, had come forward again at the moment of danger to serve as his second in command. Thinking that the allies were somewhat farther to the east than they were in fact, the French marshal marched secretly, screened by the broken and wooded ground, to the south of the fortress, and occupied the gap of Aulnois-Malplaquet (Sept. 9) to work feverishly to entrench himself. Marlborough at once giving up the siege of Mons brought his army forward to attack as rapidly as his brigades came on the scene. At this crisis the duke submitted the question of battleunwillingly, as one may imagine-to a council of war, and Eugene himself was opposed to fighting an improvised battle when so much was at stake, and it was not until the 11th that the duke delivered his attack on the now thoroughly entrenched position of the French. The battle of Malplaquet (q.v.) was by far the most desperately contested of the war. In the end Boufflers, who took command when Villars was wounded, acknowledged defeat and drew off in good order. Eugene was wounded, and Mariborough, after the most terrible experience in any soldier's life-

retired into winter quarters. The loss of the French is given variously as 7,000 and 12,000. The allies sacrificed no less, probably more, than 20,000 men.

Campaign of 1710.-In 1710 Villars lay entrenched behind a new series of lines, which he called Ne plus ultra and which extended from Valenciennes to the sea. Marlborough made no attempt to invade France from the side of Mons, for Villars at the head of the army which had been through the ordeal of Malplaquet was too terrible an opponent to pass by with impunity. In England, too, the anti-Marlborough party was gaining the upper hand in the queen's council. So Marlborough took no risks, and returning to the Lille side, captured Douai (June 26) and Béthune (Aug 26). No attack was attempted upon the lines. In Dauphiné, Berwick repulsed the Austrians and Piedmontese.

The year 1711 was Marlborough's last campaign, and it was remarkable for the capture of the Ne plus ultra lines by manoeuvres that must be recorded as being the ne plus ultra of the 18th century way of making war by stratagem. În May the sudden death of the emperor completely altered the political outlook. for his successor Charles was the coalition's claimant to the throne of Spain, and those who were fighting for the "Balance of Power" could no more tolerate a new Charles V. than they could see Louis XIV. become a Charlemagne.

In accordance with a strategic policy of passive endurance the marshal Villars remained on the defensive behind his lines, and Marlborough determined to dislodge him. What force could not achieve, the duke trusted to obtain by ruse. The lines extended from the sea along the Canche, thence to Arras, and along the Sensée to Bouchain on the Scheldt. As the western part of the lines, besides being strong, were worthless from the invaders' point of view because their capture could not lead to anything, Marlborough determined to pass the barrier between Arras and Bouchain. On July 6 Marlborough marched away to the west, as if to attack the lines between Arras and the headwaters of the Canche. Villars followed suit. The plot of the comedy now thickened. Marlborough lost his usual serenity, and behaved in so eccentric a manner that his own army thought him mad. He sent off one part of his forces to Béthune, another back to Douai, and ordered the small remainder to attack the lines between the Canche and Arras, where, as every one knew, Villars's whole army was massed. In the night of Aug. 4-5 the main army slipped off westward, at the highest possible speed. The Scarpe was crossed and then the pace was increased, though thousands of the infantry fell out and scores died from exhaustion. Five hours ahead of the French army the allies crossed the great lines unresisted. The troops concentrated at Cambrai when Marlborough, declining Villars's offer of a battle, manoeuvred farther to the east and invested Bouchain. The siege, covered by a strong "line of circumvallation" which Villars did not attempt to attack, ended with the surrender of the place on Sept. 13, and so terminated a series of manoeuvres so extraordinary as to be almost incredible. In December Marlborough was dismissed from the service in disgrace.

But Holland and Austria determined to make one last effort to impose their own terms on Louis. Eugene's army, which had been used in 1711 to influence the imperial election instead of to beat Villars, was brought back to the Low Countries. Reading the meaning of Marlborough's fall, he quietly made preparations to take over the various allied contingents into Imperial or Dutch pay. So when England seceded, Ormonde only marched away with 12,000 sullen men, while 100,000 remained with the prince.

Misfortunes at Versailles helped Eugene in his first operations, for two successive heirs apparent to the crown died within a month and all was in confusion, not to speak of the terrible misery that prevailed in the country. But the old king's courage rose with the danger and he told Villars that if the army were beaten he would himself join it and share in its fate. Villars, though suffering still from his Malplaquet wound, took command on April 20, and spun out time on the defensive until the end of May, when Ormonde's contingent withdrew. Eugene, as the defection of England had made further operations near the sea unprofitable, took Le Quesnoy (July 4) and moved thence on to Landrecies, which was closely invested. Then followed the last serious fight of the war, the battle of Denain, which saved the French monarchy and completed the disintegration of the coalition.

Denain .- In order to protect his camps around Landrecies, Prince Eugene constructed the usual lines of circumvallation with such speed that Villars, on coming up, found that they were too formidable to attack. Villars anxiously looked out for an opportunity of breaking through. At Denain, the besiegers' route crossed the Scheldt and he resolved to attack them there. The enterprise, like Marlborough's forcing of the Ne plus ultra lines, involved an extraordinary combination of force and fraud-for the point of attack was far away and the opposing army almost within cannon-shot Some days were spent by Villars in deceiving Eugene and his own army as well, as to his real intentions. Then on the night of July 23 the French army moved off silently, and by 9 AM on the 24th had completely deployed on the north bank of the Scheldt. Eugene galloped away to bring up his army from Landrecies. But, long before it arrived, Villars's troops stormed the lines. A mass of Dutch troops—spiritless since Malplaquet-were huddled into the narrow avenue between the twoentrenchments and forced back against a broken bridge. Their generals were taken. The broken mob of fugitives tamely surrendered. Eugene arrived on the other bank with some brigades of the imperial infantry, but failed to reopen the passage. Villars followed up his victory at once, capturing Marchiennes and St. Amand, and in these places all Eugene's reserve stores, pontoons and guns. On Aug. 2 Eugene broke up the siege of Landrecies and retreated by a roundabout route to Mons, while Villars's lieutenants retook Douai and Bouchain (September-October). Before the next campaign opened the treaty of Utrecht had been signed, and although the emperor continued the struggle alone for another year, the enfeebled combatants were content to accept Villars's captures of Landau (July 22, 1713) and Freiburg (Nov. 21) as decisive. The treaty of Rastatt, between Austria and France, was signed on March 7, 1714, Eugene and Villars being the negotiators.

# NAVAL OPERATIONS AND MILITARY OPERATIONS IN SPAIN

The great campaigns fought in the Rhine delta and in North Ltaly, often tend to obscure the fact that the principal objective of both sides during the war was Spain. The French could reach the theatre of operations quite easily by land, but the Austrian Imperialists had to rely entirely on Anglo-Dutch fleets to make their efforts effective. On the formation of the Grand Alliance, considerable difference of opinion arose as to how the English fleet should be used, William III, and Mariborough being in favour of a concentration in the Mediterranean, while many of the sailors advocated oceanic operations on the Atlantic coast of Spain and Portugal, and on the east coast of America.

Allied Victory at Cadiz .- Admiral Sir George Rooke was put in command of the combined fleet, consisting of 30 English ships of the line, and 20 Dutch under Admiral van Almonde, and carrying 13,000 English and Dutch troops under the Duke of Ormonde. Rooke was instructed to seize Cadiz as a base for future operations in the Mediterranean. Inevitable complications, however, arose. It was judged inexpedient to compel the Spaniards to acknowledge the Archduke Charles as their rightful king, by means of a bombardment, and they, being not unnaturally somewhat backward in receiving the candidature of an Austrian Prince, lent no support to the Anglo-Dutch arms. Consequently the attempt on Cadiz could not be pushed too vigorously and may be said to have failed. Rooke was already steering north again when he learnt that the Spanish treasure fleet had entered Vigo Bay, protected by Admiral Châteaurenault with a French squadron. The Allies at once determined to prevent the French obtaining the treasure by capturing it themselves, and, entering the bay, Or-

monde's troops were landed to attack the forts, while Rooke pushed forward a special advance squadron and forced the boom which the French had laid across the entrance to the inner harbour (Oct. 12, 1702). In the furious engagement which followed, Rooke sank and captured the 24 French warships and the 17 Spanish galleons, and recovered bullion worth two million pounds.

Portugal Joins Allies.—In 1703 Portugal joined the Allies so that Lisbon could be used as a naval base, but Admiral Clowdisley Showlel was sent to the Mediterranean too late to achieve any object, and many of his ships on their return were destroyed in the Channel during the great storm of Nov. 27. Great efforts were made in 1704 to bring about something decisive. Rooke sailed in February and landed the Archduke Charles at Lisbon, together with 2,000 English and Dutch troops to co-operate with the Portuguese in an invasion of Soain.

Rooke carried his fleet through the Straits, hoping to be able to make an attack on Toulon in concert with the duke of Savoy, who had recently joined the alliance. This, in conjunction with Marlborough's march across Germany to Blenheim, would have been a fine counterstroke to the French thrust at Vienna, but as often happened afterwards, Savoy failed to co-operate. An attempt was made to win over Barcelona to the archduke's cause, but the governor refused to admit the allied forces. Meanwhile, the Comte de Toulouse succeeded in bringing the French Brest fleet into the Mediterranean and though Rooke sighted him, his ships were too foul to catch the French, who entered Toulon unopposed, and so united their principal Atlantic and Mediterranean forces. Rooke therefore passed the Straits and met Shovell and the Dutch between Cape St. Vincent and Cadiz, and then reentered the Mediterranean to watch for the French.

Gibraltar Taken by Allies.—At this juncture the allied leaders took the memorable decision to capture Gibraltar and so advance their sphere of activity 300 miles beyond Lisbon. After lengthy preparations the attack was begun by Admiral George Byng, who bombarded the fortress with a special squadron on July 23 (1704), while Prince George of Hesse-Darmstadt, the Imperial representative, landed 1,800 English marines and cut off the fortress on the land side. Gibraltar being only weakly held, an attacking force was soon landed from the ships, and the place surrendered next day.

Hardly was this great success achieved than Toulouse was reported sailing south-west to recapture the fortress. Rooke left Prince George and 900 marines in Gibraltar and went in search of Toulouse, having had to spend some time watering his fleet at Tetuan. On Aug. 9 the fleets were in sight of each other, but the French retreated and then attempted to double back again close inshore. Rooke, however, sighted them slipping past and brought them to action off Malaga on Aug. 13, each side having about 50 ships of the line. The French were decisively beaten.

The allies returned to Lisbon to refit, leaving Prince George with all the marines and some ships, guns and stores to defend Gibraltar. He was soon attacked by land and sea in overwhelming force, but was relieved by Admiral Leake, who arrived from Lisbon where he had been left in command by Rooke, who had gone home. Entering the bay on Oct. 25, the day on which the final attack was to take place, he destroyed the French flottila, enfiladed the Franco-Spanish entrenchments on shore, and revictualled and reinforced the garrison. The French now sent Marshal Tessé with a siege train to command the attack by land, and Prince George was again hard pressed, but Leake again reinforced and revictualled him in December. At last, on March 10, 1705, Leake destroyed de Pointis' force at Marbella, and Tessé raised the siege.

Allies Invade Spain.—The Allies now took the offensive, Shovell and Lord Peterborough coming out from England as joint commanders. Picking up Leake at Lisbon and Prince George at Gibraltar, they sailed to Barcelona and besieged it. It was finally captured and occupied on Oct. 3, 1705, but Prince George was killed during the assault. Philip, the Bourbon candidate, hurried to Catalonia with Marshal Tessé to recapture it, and a squadron put out from Toulon. Leake, however, was able to foil all the French efforts and forced them to raise the siege on April 30, 1706.

Leake, who was again left in command of the fleet, made good use of his time by capturing Cartagena (June 1, 1706) and Alicante (Aug. 24, 1706), and then sailing to the Balearic Islands and capturing Mallorca (Majorca) and Iviza in September.

Meanwhile, the allied troops advanced from Portugal and captured Madrid (June 26, 1706) and proclaimed the archduke Charles. The Castilians, however, did not relish invasion by the Portuguese, and being rallied by Berwick, compelled the allies to retreat southeast to Valencia, on the coast

Closing Operactions.—In July and August combined operations were again attempted against Toulon, but again Savoy defaulted, and Shovell, returning with 12 of the line, was wrecked on the Scilly Isles on Oct. 22, 1707, together with several other ships which were lost with all hands. Leake now exercised the permanent command-in-chief and operated in the Mediterranean with great success, reducing Sardinia for the Imperialists in August 1708. In September General Stanhone captured Minorca.

The war in Spain languished owing to the increasing exhaustion of both sides and the apathy of the Spaniards. Stanhope, however, in 1710 persuaded the Imperalisit troops to join him in another invasion, and they actually succeeded in bringing the archduke Charles to Madrid. Previous conditions, however, reasserted themselves, and the allies were again driven east to the coast by the duc de Vendôme, the new general of the Franco-Spanish forces

Stanhope was defeated and captured on Dec. 9, 1710, at Brihuego, and the Imperialists were only just able to make good their retreat to Barcelona, which they held till the Peace of Utrecht, though the Catalans themselves heroically defended it against Berwick till Sept. 12, 1714. At sea, Admiral Wager captured a Spanish treasure fleet off Cartagena in May 1708, and Duguay Trouin captured an English convoy off the Lizard on Oct. 20. In 1710 Commodore Martin's squadron, assisted by American Colonists, captured Nova Scotia.

Bibliography.—O. Troude, Batailles Navales de la France (1867); J. S. Corbett, England in the Mediterranean, 2 vols. (1917); Geoffrey Callender, Life of Sir John Leake, 2 vols Navy Record Society (1920) contains a bibliography. (G. A. R. C.; W. C. B. T.)

SPANNER (WRENCH) is a tool for turning nuts, setscrews, coachscrews, spindles, including those of hydrants and valves. (Spanners in the U.S. are called "open-end wrenches," except for the English "box spanner," which in America is a "socket wrench.") The principal forms are the straight wrenches, single-ended or double-ended, the angle, which enables a nut to be turned in a confined space, and the socket wrenches (box spanners) enabling the nut to be readily turned from above or from the side, without slip. Socket wrenches are light and strong, being assembled in sets.

The structural wrench has a long handle terminating in a tapered end. The platelayer or track wrench is also very long, but with parallel handle; it gives great power for dealing with fish-plate bolts. The pin and the hook wrenches turn circular nuts, the one with a pin entering a drilled hole on the nut, the other with a hook catching in a slot. The cap wrench or axle-spanner grips on four surfaces of a road wheel nut. A ratchet wrench permits resetting of the handle without removing the wrench, giving short strokes of the handle. Power-operated wrenches or "nut runners" are employed for quick loosening and tightening. Two common adjustable wrenches are the monkey wrench (and its specialized companion, the pipe wrench) having one jaw adjustable in line with the axis of the handle, and the adjustable open-end wrench (commonly called the crescent) which has one jaw adjustable across the axis of the handle. Chain wrenches are used to turn large diameter pipes.

SPARK or SPARKING PLUG: see Motor Car and Motor Car Engines: Their Operation and Care.

**SPARK PHOTOGRAPHY** derives its name from the type of illumination employed. The light for the photograph is produced by a small electric spark of extremely short duration and great intensity.

This method finds many applications in the photography of rapidly moving objects; for example, the earliest known spark photograph was an ordinary snapshot of a newspaper clipping fastened to the surface of a rapidly spinning disk. The size of the spark is so small that it can be used to project a silhouette directly on the photographic film, and, in ordinary practice, the conventional camera with its lens is not required. One common arrangement of the equipment is shown in the accompanying diagram. There, the object to be photographed, a bullet, travels between the spark and the plate, and the spark is fired by a trigger circuit when the bullet passes in front of the plate.

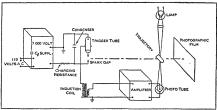

FIG. 1.—SCHEMATIC WIRING DIAGRAM OF SPARK PHOTOGRAPHY AP-

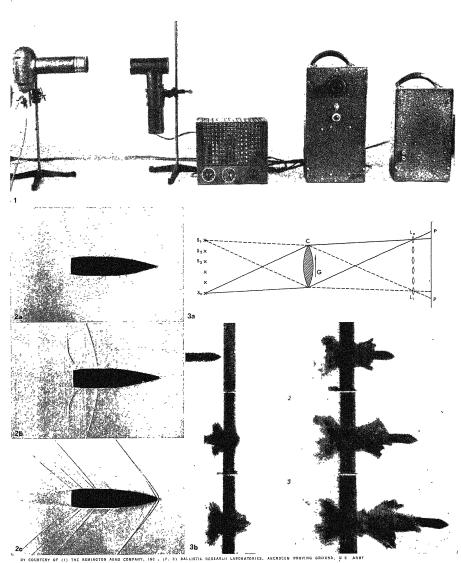

The spark itself is generated by the discharge of a high-voltage capacitor across a gap between two electrodes. The circuit consists of the condenser, the gap and an electronic switch element which prevents discharge until the instant desired. Electrical energy is slowly stored in the condenser over a relatively long period of time and is discharged with sudden violence through the gap at the instant the switch is effectively closed by a control signary.

Many designs of gaps and switches were devised for different applications. The operating capacities and voltages also varied widely, ranging from 4,000 volts with 1 microfarad to 40,000 volts with 0.01 microfarad. But, in general, the circuit produces a spark sufficiently intense to give good exposures at 4 ft. to 20 ft. and of so short a duration that the effective part of the light lasts only 1 or 2  $\times$  10  $^{-6}$  sec. Also, the light is rich in ultra-violet radiation, thus further increasing its photographic effectiveness.

Firing the spark at the desired time during the brief period the moving object is in front of the plate is usually the most difficult feature of this photographic system, and many ingenious methods of triggering were developed. The function of the trigger circuit is to send a control signal to the discharge switch element at the proper instant. This operation must be extremely precise; a tolerance of 10<sup>-5</sup> sec. is common. The particular method chosen depends on the application. Occasionally, processes external to, but related to, the moving object are used, such as the muzzle blast or the recoil in the case of ballistic photography near the gun, but ordinarily some property of the object itself starts the trigger operation.

The simplest of all methods is the make or break contact. If the object is made of steel, a solenoid pickup can be used; if it can be charged to a high potential, an electrostatic pickup is suitable; if the geometry of its motion can be arranged so that it cuts the path of a beam of light, a photoelectric pickup gives good results; or, if the object is travelling faster than the speed of sound, a sonic pickup will work.

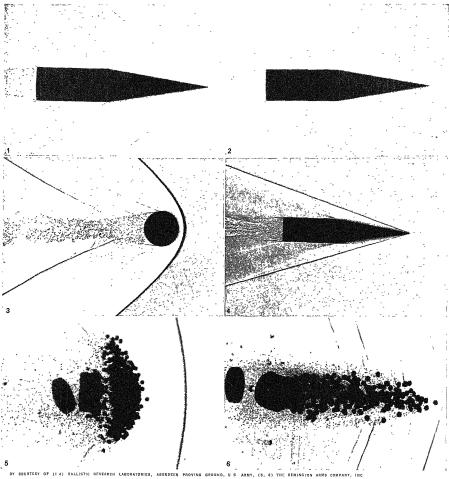

The over-all operation is conveniently illustrated by tracing through the sequence of events involved in taking the spark photograph of a bullet in flight by the apparatus shown in the diagram. The room is darkened, the photographic plate put in position, and the gun fired. Since a photoelectric pickup is used, the gun has been aimed so that the trajectory intersects the beam of light from the lamp to the phototube. As the bullet interrupts this beam, it changes the amount of light falling on the phototube and thereby generates a voltage pulse in the electronic circuit. This pulse is amplified and used to fire a gas discharge tube in the output of the amplifier. The discharge tube in turn sends a surge of current through the primary of an induction coil, and the high voltage surge resulting in the secondary is applied to the control element

# APPARATUS AND EXAMPLES OF SPARK PHOTOGRAPHY

of the trigger tube, the switch of the discharge circuit. Secondary emission ionizes this tube, thus effectively closing the switch, the condenser discharges through the spark gap, and the spark photograph is taken. The duration of the light is sufficiently short to arrest the motion of even the highest velocity projectiles.

Applications to Ballistics.—Spark photography is of great value to the ballistic engineer, enabling him to answer many questions on the flight of bullets and the flow of the air about them. Such questions as that of determining the distance from the muzle at which the velocity of the erupting gas becomes less than that of the bullet are readily answered. It is of particular interest in the case of shot shells where the disposition of the shot and wads may be easily observed. Work of this nature led to the commercial development of shot shells without the top card wad over the shot, for it was observed by spark photography that this wad interfered with the proper flight of the shot.

Aerodynamics Range.—As the projectile flies from gun to target, it experiences violent resistive forces because of its high velocity motion through the air, and, if the flight path is to be computed, these forces must be measured. Here, spark photography gives the ballistician a tool of great precision, in the so-called "aerodynamics range." The projectile is fired into a long, enclosed gallery containing from 10 to 25 spark photography stations spaced at intervals along its length. As the projectile passes each station in turn, two spark pictures are taken in perpendicular planes (one horizontal, say, and the other vertical) and the time of the event is recorded on a high-speed chronograph.

Thus, each pair of spark photographs records the position of the projectile at a measured time, and all of the records can be combined to determine the retardation of the projectile's motion and the aerodynamic drag. The inclination of the projectile's axis to its direction of motion can also be measured from each pair of pictures, and from these measurements the projectile's stability can be computed.

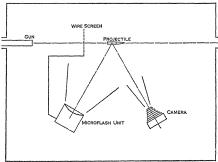

FIG. 2.—DIAGRAMMATIC DRAWING OF A TEST CHAMBER FOR TAKING A MICROFLASH PHOTOGRAPH OF A PROJECTILE IN FLIGHT

Multiple Spark Photography .- Many problems in ballistics require detailed knowledge of extremely high-speed action taking place in a relatively small space, such as the penetration of armour plate or the detonation and subsequent fragmentation of highexplosive shell. Again, spark photography furnishes the key to the instrumentation through the so-called "multiple spark apparatus." In this apparatus spark photography and optics are combined to give a rapid series of pictures of the action taking place within a confined space. It consists of a number of spark gaps mounted in a common plane, a large lens or mirror with its optical axis perpendicular to the plane of the spark gaps, and a corresponding number of cameras with their lenses placed (coplanar) at the conjugate focuses of the spark gaps. The elements are arranged so that the action takes place close to the lens (or mirror) in order to get the maximum field of view. The cameras are focused on the action. By the optical system the light from each gap is converged so that it enters only the particular camera located at the gap's conjugate focus. Hence, only the film in one camera is exposed by the light from one spark. The sparks are fired one after another at controlled intervals of time and the pictures resulting form a series of silhouettes each looking at the action from a slightly different point of view. The sparks can be operated at the almost unbelievable rate of 1,000,000 per second, and their terrific speed is sufficient to record the motion of such instantaneous phenomena as the detonation wave travelling along the length of an exploding projectile.

Shock Wave Phenomena.—One of the most spectacular characteristics of spark photographs is the shadows produced by compression waves in the air These are seen as lines, usually curved, with a dark front edge and a light rear edge. Strong compression waves, known as shock waves, have fronts that amount to surfaces of very small thickness through which the pressure, density, temperature, and, consequently, index of refraction change violently (roughly similar to the fronts of waves rolling up a shallow beach). The rays of light from the spark passing tangent to these wave surfaces are refracted to form lines of alternate dark and bright representing the projection of the wave surfaces on the photograph. The technique is very sensitive and wave patterns are recorded in fine detail.

Shock waves are produced in air by any disturbance that is sufficiently strong and abrupt. Electric sparks, explosives, projectiles and aircraft travelling at speeds close to or greater than the speed of sound, all generate shock waves. An example of pure wave photography is found in the study of the reflection of shock waves from solid surfaces. The wave pattern surrounding bodies at transonic and supersonic velocities are of particular interest since they tell much about the nature of the air flow over the body. Even the turbulent layer of air next to the projectile's surface and the wake following it are visible. (R. E. E.; A. C. Cs.)

SPARKS, JARED (1789-1866), U.S. historian and educator, was born in Willington, Conn., on May 10, 1789. He made a brilliant record in his studies and became a schoolteacher. In 1809-11 he attended Phillips Exeter academy, where he met John G. Palfrey and George Bancroft, two schoolmates, who became his lifelong friends. He graduated from Harvard (A.B., in 1815 and A M., in 1818); taught in a private school at Lancaster, Mass., in 1815-17; and studied theology and was college tutor in mathematics and natural philosophy at Harvard in 1817-19. He refused a professorship at Bowdoin college for the pastorate of a Unitarian church in Baltimore. In 1821 he founded The Unitarian Miscellany and was chosen chaplain of the national house of representatives, where he made many influential friends. Probably his natural bent toward writing as well as the state of his health was responsible for his leaving the ministry in 1823 and purchasing the North American Review, of which he had been acting editor in 1817-18 and which he edited until 1830. By good management he made this periodical a financial success and the arbiter of literature in New England. But although he founded The American Almanac and Repository of Useful Knowledge in 1830, the major portion of his energy after 1826 was devoted to historical scholar-

Born in the shadow of the great figures of the Revolution, he did his most important work in The Life and Writings of George Washington (12 vol., 1834-37) and The Works of Benjamin Pranklin; With Notes, and a Life of the Author (10 vol., 1836-40). Another valuable project was The Library of American Biography (first series, 10 vol., 1834-38; second series, 15 vol., 1844-47), which he edited and to which he contributed a number of articles. Of lesser value are The Life and Travels of John Ledyard (1828); The Diplomatic Correspondence of the American Revolution (12 vol., 1829-30); The Life of Gouverneur Morris (3 vol., 1832); and Correspondence of the American Revolution, Being Letters of Eminent Men to George Washington (1853).

Sparks had done some of the research for his book on Washington in Europe, and in 1840-41 he continued his studies abroad in the history of the American Revolution. In the course of his research he discovered in the French archives the red-line map, which, in 1842, came into international prominence in connection

with the dispute over the northeastern boundary of the United States In 1842 he delivered 12 lectures on American history before the Lowell institute in Boston. In 1839-49 he was McLean professor of ancient and modern history at Harvard. His appointment to this position, says his biographer, was "the first academic encouragement of American history, and of original historical research in the American field."

The esteem in which he was held in his day is shown not only by the large sale of his works but by his election to the presidency of Harvard in 1849. He retired in 1853 because of failing health, and devoted the rest of his life to his private studies. For several years he was a member of the Massachusetts board of education. He died on March 14, 1866.

His valuable collection of manuscripts and papers went to Harvard; and his private library and maps were bought by Cornell university, Ithaca, N.Y. He was a pioneer in collecting, on a large scale, documentary material on American history, and in this and other ways rendered valuable services to historical scholarship in the United States.

See H B. Adams, The Life and Writings of Jared Sparks (2 vol., 1893), and J. S. Bassett, The Middle Group of American Historians (1917).

SPARKS, a city of Washoe county, Nevada, U.S., east of Reno near the Truckee river. The population in 1950 was 8,203 by the federal census and in 1940, 5,318. It is served by the Southern Pacific railway, which established the city in 1905, and it is a railroad division point.

The city was named for John Sparks, governor of Nevada at the time of the city's founding Sparks is in an irrigated agricultural area where hay, potatoes and onions are raised. Near by are gold and silver mines.

**SPARROW**, a word originally meaning any small bird, now restricted to those of the types enumerated below.

- (1). The house sparrow (Passer domesticus) is "the sparrow" par excellence. Thriving best in the neighbourhood of man, this bird is common throughout the northern parts of Europe and Asia and has been introduced into North America (in 1851) and the British colonies.
- (2). The tree sparrow, or mountain sparrow (P. montanus), both sexes of which resemble the male house sparrow, but are distinguished by the rufous crown and doubly barred wings, is a local species in England. In China, it is abundant and replaces the house sparrow near houses and in towns.
- (3). The hedge sparrow or dunnock (Prunella modularis), belonging to the thrushes (q.w.), is a little brown-backed bird with an iron grey head and neck. It is widely distributed throughout Europe.
- (4). The reed-sparrow or reed-bunting is, as the second name implies, a bunting (q.v.).
- (5). The numerous American sparrows are also buntings (q, v). Among them may be mentioned the song sparrow (Melospiza melodio) of which about 20 sub-species are recognized. It has a fine song. The chipping sparrow (Spizella passerina) is a confiding, humble little bird, with no great attractions but his manners. The savannah sparrow (Passerculus sandwichensis) is abundant in the maritime provinces of Canada, but breeds south to Iowa. The grasshopper sparrow (Animodramus savannarum) is also a common form, but its skulking habits and insect-like notes cause it to be overlooked. The lark sparrow (Chondestes gramma-cus) is common in the Mississippi valley east of the great plains; it has a pleasant if hurried song. The fox sparrow (Passerella iliaca) has also a fine song; it breeds in north Canada and Alaska, wintering from Ohio southward.

SPARTA (Gr. Σπάρτη οτ Λακεδαίμων), an ancient city in Greece, the capital of Laconia and the most powerful state of the Peloponnese. The city lay at the N. end of the central Laconian plain, on the right bank of the Eurotas, S. of its junction with the Oenus (mod. Kelefina), commanding the only land-routes into Laconia, the Oenus and Eurotas valleys from Arcadia, and the Langáda Pass over Mt. Taygetus from Messenia. At the same time its distance (27 m. from its port, Gythium) made it invulnerable from the sea.

#### ARCHAEOLOGY

Until 1905 the visible ancient buildings at Sparta were the theatre, the "Tomb of Leonidas," a quadrangular building of immense blocks containing two chambers; the foundation of a bridge over the Eurotas; a curved structure since found to be a Hellenic retaining wall restored in Roman times, and some late Roman fortifications, buildings and mosaic pavements. Inscriptions, sculptures and other objects were collected in the museum, or built into houses or churches. Excavations were carried on near Sparta, on the site of the Amyclaeum (1890 Tsountas, 1904 Furtwängler) at the shrine of Menelaus in Therapne (1833, 1841, Ross; 1889, 1900, Kastriotis) and at the "round building" (1892 and 1893 American School at Athens). But no organized work was tried in Sparta itself.

Systematic exploration, however, began with the excavations of the British School at Athens, at Thalamae, Geronthrae, and Angelona near Monemvasia, in 1904, and at Sparta itself in 1906. A "small circus" described by Leake, was found to be a theatrelike building constructed soon after A.D. 200 round the altar and in front of the temple of Artemis Orthia. Here musical and gymnastic contests took place as well as the famous flogging-ordeal (diamastigosis). The temple, of the 2nd century B.C overlies an older temple of the 6th century, and close beside it were found remains of a yet earlier temple, dating from the 9th or even the 10th century. The votive offerings in clay, amber, bronze, ivory and lead found in profusion within the precinct range from the 9th to the 4th century B C.; they prove that Sparta reached her artistic zenith in the 7th century and declined in the 6th. In 1907 the sanctuary of Athena "of the Brazen House" (Χαλκίοικος) was found on the Acropolis immediately above the theatre, and though the temple is destroyed, fragments of capitals in Doric style remained; also the longest extant archaic inscription of Laconia, and numerous bronze nails, plates and votive offerings of great interest. The Greek city-wall, built in stages from the 4th to the and century, has a circuit of nearly 6 m. (Polyb. ix. 21). The late Roman wall enclosing the Acropolis, probably dates from the years following the Gothic raid of A.D. 262. A number of points of Spartan topography, have been fixed in accord with the description of Pausanias. In 1910 the town of the "Mycenean' period on the left bank of the Eurotas a little to the S.E. was found to be roughly triangular, with an area approximately equal to that of Sparta, but nothing is left but foundations and potsherds. More recently, excavation of the theatre has yielded, besides inscriptions and small objects, a remarkable fifth century statue of a warrior.

### HISTORY

Prehistoric Period .- Tradition relates that Sparta was founded by Lacedaemon, son of Zeus and Taygete. But Amyclae and Therapne (Therapnae) were in early times of greater importance than Sparta, the former a Minyan foundation a few miles to the south of Sparta, the latter the Achaean capital of Laconia and the seat of Menelaus. Eighty years after the Trojan War, according to the traditional chronology, the Dorian migration took place (see Greece; History [Ancient]). A band of Dorians (q.v.) united with a body of Aetolians to cross the Corinthian Gulf and invade the Peloponnese from the north-west. The Aetolians settled in Elis, the Dorians pushed up to the headwaters of the Alpheus, where they divided into two forces, one of which, under Cresphontes, subdued Messenia, while the other, led by Aristodemus, made its way down the Eurotas valley and gained Sparta, which became the Dorian capital of Laconia. In reality this Dorian immigration probably consisted of a series of inroads and settlements rather than a single expedition. The newly founded state did not at once become powerful; the turning-point is marked by the legislation of Lycurgus (q.v.), who instituted that training which was its distinguishing feature and the source of its greatness. Nowhere else was the individual so thoroughly subordinated to the interest of the state. The whole education of the Spartan was designed to make him an efficient soldier. Obedience, endurance, military success-these were the aims constantly kept in view, and all other ends took a secondary place.

The Expansion of Sparta.—The first step, in the reign of

SPARTA 171

Archelaus and Charillus, was to secure the upper Eurotas valley, conquering the border territory of Aegys. Archelaus's son Teleclus is said to have taken Amyclae, Pharis and Geronthrae, mastering the central Laconian plain and the eastern plateau between the Eurotas and Mt. Parnon; his son, Alcamenes, by the subjugation of Helos, brought the lower Eurotas plain under Spartan rule. About this time, the Argives, whose territory included the whole east coast of the Peloponnese and the island of Cythera (Herod. i. 82), were driven back, and the whole of Laconia was incorporated in the Spartan state. Under Alcamenes and Theopompus a war broke out between the Spartans and the Messenians, which, after 20 years, ended in the capture of Ithome and the subjection of the Messenians, who were forced to pay half the produce of the soil as tribute. An attempt to throw off the yoke resulted in a second war, conducted by the Messenian hero Aristomenes (q.v); but Spartan tenacity prevailed, and Messenia was made Spartan territory, its people being reduced to the status of helots (q v.).

This extension of Sparta's territory was viewed with apprehension by her neighbours in the Peloponnese. Arcadia and Argos had vigorously aided the Messenians in their two struggles; only the Corinthians supported the Spartans, doubtless through jealousy of their neighbours, the Argives. At the close of the second Messenian War (c. 631 B.C.) no power could hope to cope with that of Sparta save Arcadia and Argos. In the 6th century Sparta made a vigorous attack on Tegea, the most powerful of the Arcadian cities, but it was not until the middle of the century that Tegea was forced to acknowledge Spartan overlordship, though retaining its independence. The final struggle for Peloponnesian supremacy was with Argos; but Argos was now no longer at the height of its power; it could not count on the assistance of Arcadia and Messenia, since the latter had been crushed and the former had acknowledged Spartan supremacy. A victory, won about 546 B.C., made the Spartans masters of the Cynuria, the borderland between Laconia and Argolis. The final blow was struck by King Cleomenes I. (q.v.), and left Sparta without a rival in the Peloponnese. By the middle of the 6th century, Sparta had come to be acknowledged as the leading state of Hellas and the champion of Hellenism. Croesus of Lydia had formed an alliance with her; to her the Greeks of Asia Minor appealed to withstand the Persian advance and to aid the Ionian revolt; Plataea asked for her protection; and at the time of the Persian invasion under Xerxes (see Graeco-Persian Wars) no state questioned her right to lead the Greek forces on land and sea. Of such a position Sparta proved herself unworthy. She could never rid herself of her Peloponnesian outlook sufficiently to throw herself heartily into the affairs of the greater Hellas. She was not a colonizing State, and had no share in the expansion of Greek commerce and Greek culture. Her military greatness formed her sole claim to lead the Greek race; that she should truly represent it was impossible.

Constitution .- Of the internal development of Sparta down to this time but little is recorded. This was attributed to the stability of the Spartan constitution, but it is, in fact, due also to the absence of historical literature at Sparta, to the small part played by written laws, expressly prohibited by an ordinance of Lycurgus, and to the secrecy of oligarchical rule. At the head of the state stood two hereditary kings, of the Agiad and Eurypontid families, equal in authority, though the Agiad king received greater honour in virtue of the seniority of his family (Herod. vi. 51, 52). This dual kingship was explained by the tradition that on Aristodemus's death he had been succeeded by his twin sons. Aristotle describes the kingship at Sparta as "a kind of unlimited and perpetual generalship" (Pol. iii. 1285a). Here also, however, the royal prerogatives were curtailed; the king lost the right of declaring war, was accompanied to the field by two ephors, and was supplanted by the ephors in the control of foreign policy. The kings became mere figure-heads, and the real power was transferred to the ephors and to the gerousia (q.v.). In the powers exercised by the assembly of the citizens or apella (q.v.) we cannot trace any development, owing to the scantiness of our sources. The Spartan was essentially a soldier, trained to obedience and endurance, he became a politician only if chosen as ephor for a single year or elected a life member of

the council after his 60th year had brought freedom from military service

Social System.—Spartiates were debarred by law from trade or manufacture, which rested in the hands of the perioeci (q.v.), and were forbidden to possess either gold or silver, the currency consisting of bars of iron. Wealth was, in theory, derived entirely from landed property, and consisted in the annual return made by the helots, who cultivated the plots of ground allotted to the Spartiates. But this attempt to equalize property proved a failure; from early times there were marked differences of wealth within the state, and these became greater after the law of Epitadeus removed the legal prohibition of the gift or bequest of land. The number of full clitzens, 8,000 at the beginning of the 5th century, had sunk by Aristotle's day to less than 1,000, and had further decreased to 700 in 244 B.C.

The Persian Wars and After.-The beginning of the 5th century B C. saw Sparta at the height of her power; but after the Persian Wars the Spartan supremacy could no longer remain unchallenged. Sparta despatched an army in 490 BC. to aid Athens in repelling the armament sent against it by Darius. But it arrived after the conflict had been decided at the battle of Marathon. In the second campaign Sparta assumed the command of the combined Greek forces by sea and land. Yet, in spite of the heroic defence of Thermopylae by Leonidas (q.v.) the glory of the decisive victory at Salamis (q.v) fell in great measure to the Athenians, and their patriotism and energy contrasted strongly with the hesitation of the Spartans and their selfish policy of defending the Peloponnese only. By the battle of Plataea (479 B.C.), won by a Spartan general, the state partially recovered its prestige, but only so far as land operations were concerned; the victory of Mycale, won in the same year, was achieved by the united Greek fleet, and the capture of Sestos, which followed, was due to the Athenians. The perils and the glories of the Persian War were left to Athens, who, though at the outset merely the leading state in a confederacy of free allies, soon began to make herself the mistress of an empire. Sparta for a time took no steps to prevent this. Moreover, Sparta's attention was occupied by troubles nearer home-the plots of Pausanias not only with the Persian king but with the Laconian helots; the revolt of Tegea (c. 473-471); the earthquake which in 464 devastated Sparta; and the rising of the Messenian helots, which immediately followed. The insulting dismissal of Athenian troops which had come to aid the Spartans in the siege of the Messenian stronghold of Ithome, the consummation of the Attic democracy under Ephialtes and Pericles (q.v.), and the conclusion of an alliance between Athens and Argos united with other causes to bring about a rupture between the Athenians and the Peloponnesian League. In the so-called first Peloponnesian War Sparta herself took but a small share beyond helping to defeat the Athenians at Tanagra in 457 B.C.

Peloponnesian War.—A fresh struggle, the great Peloponnesian War (q.v.), broke out in 431 B.C. This may be to a certain extent regarded as a contest between Ionian and Dorian, or between the democratic and oligarchic principles of government; but at bottom its cause was neither racial nor constitutional, but economic. The maritime supremacy of Athens was used for comercial purposes, and important members of the Peloponnesian

confederacy, whose wealth depended largely on their commerce, notably Corinth and Megara, were being slowly but relentlessly crushed. Sparta remained unaffected, but she was forced to take action by the pressure of her allies. She did not prosecute the war with any vigour. her operations were almost confined to an annual inroad into Attica, and when in 425 B.C a body of Spartiates was captured by the Athenians at Pylos, she was anxious to terminate the war on any reasonable conditions. That the teims of the Peace of Nicias (421), were rather in favour of Sparta than of Athens was due almost entirely to an individual Spartan, Brasidas (q v.). The final success of Sparta and the capture of Athens in 405 were brought about partly by the treachery of Alcibiades. Funds were gained by subsidies from Persia, and Spatta found in Lysander (q.v.) an admiral of boundless vigour.

Spartan Empire.-The fall of Athens left Sparta once again supreme in the Greek world and demonstrated clearly her total unfitness for rule. Everywhere democracy was replaced by a philo-Laconian oligarchy, under a Spartan harmost or governor, and even in Laconia itself the narrow and selfish character of the Spartan rule led to a serious conspiracy. Under the energetic rule of Agesilaus, it seemed as if Sparta would pursue a Hellenic policy and carry on the war against Persia. But troubles soon broke out in Greece, Agesilaus was recalled from Asia Minor, and his schemes and successes were rendered fruitless Further, the naval activity displayed by Sparta during the closing years of the Peloponnesian War abated when Persian subsidies were withdrawn. İn 394 B.C. the Spartan navy under Peisander was defeated off Cnidus by the Persian fleet under Conon and Pharnabazus, and Sparta ceased to be a maritime power. In Greece itself, meanwhile, the opposition to Sparta was growing increasingly powerful, and the Spartans felt it necessary to rid themselves of Persian hostility. They therefore concluded with Artaxerxes II. the humiliating Peace of Antalcidas (387 B.C.), by which they surrendered to the Great King the Greek cities of the Asia Minor coast and of Cyprus After a desultory war with Thebes over the independence of the Boeotian towns, the citadel of Thebes was treacherously seized by Phoebidas in 382 and held by the Spartans until 379 B.C. In 371 a fresh peace congress was summoned at Sparta. Again the Thebans refused to renounce their Boeotian hegemony, and the Spartan attempt at coercion ended in the defeat of the Spartan army at the battle of Leuctra and the transfer of the Greek supremacy from Sparta to Thebes.

Decline of Sparta .- In the course of three expeditions to the Peloponnese, conducted by Epameinondas (q v), the greatest soldier and statesman Thebes ever produced, Sparta was weakened by the loss of Messenia and by the foundation of Megalopolis as the capital of Arcadia. On Epameinondas's fourth expedition Sparta was again within an ace of capture, but the danger was averted; and though at Mantineia (362 B.C.) the Thebans, together with the Arcadians, Messenians and Argives, gained a victory over the combined Mantinean, Athenian and Spartan forces, yet the death of Epameinondas in the battle more than counterbalanced the Theban victory. But Sparta had neither the men nor the money to recover her lost position, and the continued existence on her borders of an independent Messenia and Arcadia kept her in constant fear for her own safety. No Spartiate fought on the field of Chaeroneia (338 B.C.). After the battle, however, she refused to submit voluntarily to Philip of Macedon, and was forced to do so by the devastation of Laconia and the transference of certain border districts to the neighbouring states of Argos, Arcadia and Messenia. During the absence of Alexander the Great in the East, Agis III, revolted, but the rising was crushed by Antipater, and a similar attempt after Alexander's death was frustrated by Demetrius Poliorcetes in 294 B.C. Twenty-two years later the city was attacked by Pyrrhus (q.v.), but the formidable enemy was repulsed. About 244 BC. an Aétolian army overran Laconia, carrying off, it is said, 50,000 captives.

Attempts at Social Revolution.—This and other ignominious defeats of Sparta showed that she had shared, but in an unusual degree, in the general decay of Greece. On the accession of Agis IV. (q.v.) in 244 B.C. the citizen body had by the concentration of wealth in a few hands shrunk to a few hundred; the

rest of the inhabitants were in their debt and their power The Lycurgan constitution was ignored and Phylarchus (Plutarch's chief authority) gives us the usual picture of luxury and degeneracy. Agis by popular agitation was able to carry a resolution through the apella for a restoration of the Lycurgan discipline, together with a redivision of lands and a cancellation of debt. His fellow-king Leonidas opposed, but a section of the wealthy landowners, led by Agis's uncle Agesilaus, were in favour of a cancellation of debts, especially mortgages. With their assistance Agis was able to conciliate the ephors, remove Leonidas and replace him by his son-in-law Cleombrotus. The land was to be divided into "an inner ring about Sparta of 4,500 Spartan lots, and that in the outer ring into 15,000 lots for Perioeci; as there were nothing like 4,500 Spartans he proposed to fill up the number from Perioeci and selected metics in sympathy with Spartan institutions" (W W. Tarn in The Hellenistic Age, 1923, p. 134). Agesilaus persuaded him to divide his programme into two halves, the cancellation of debts being carried through first. Immediately after this measure had been passed, Agesilaus with the other ephors sent Agis north with an army to assist the Achaean league against the Actolian league During his absence the two sections of the wealthy class reunited and the division of lands was prevented Cleombrotus was expelled and Agesilaus brought back Leonidas. Agis on his return declined to use force to prevent the reaction directed by the Ephorate, took sanctuary and was killed by a trick To prevent a recurrence of a social revolution, Leonidas forcibly married Agis's widow to his son Cleomenes, who was, however, converted by his wife and the Stoic Sphaerus to Agis's views Thirteen years after Agis's death he came to the throne as Cleomenes III. (q v). He picked a quarrel with the Achaean league in order to be sent out in command of mercenaries, returned to Sparta, killed 14 of his opponents and exiled eighty. He carried through the division of land as contemplated by Agis (reserving 80 lots for the exiles), cancelled debts, and withdrew all the ephors' chairs except one, which he occupied himself His war with the Achaean league now became a series of sensational victories, but the league finally secured the aid of Antigonus of Macedonia who forced Cleomenes to flee to Egypt.

Sparta fell back into its previous abject condition, until the rise of the tyrant Nabis, of whom we have only extremely hostile accounts. He abolished debts, redistributed land, taxed the wealthy heavily for the expense of the Lycurgan common meals, and extended the scope of the revolution by liberating helots. His stern reign is marked by another sudden renaissance of Sparta's military power: Sparta was indeed the only Greek power which was able to resist the legions of Flamininus the conqueror of Macedon. Flamininus failed to capture Sparta and in his final settlement left Nabis undisturbed in Laconia, though not in Argos. The experiment was brought to an end by the assassination of Nabis by the Aetolians: in the ensuing confusion Philopoemen (q.v) the general of the Achaean league captured the city, destroyed the Lycurgan constitution of Nabis, and attached the state to the Achaean league. By his dexterity he was able to frustrate later attempts at revolution; and after the annexation of Greece by Rome Sparta has no history worth recording.

Mediaeval Sparta.—In A.D. 396 Alaric (q.v.) destroyed the city and at a later period Laconia was invaded and settled by Slavonic tribes. The Franks, on their arrival in the Morea, found a fortified city named Lacedaemonia occupying part of the site of ancient Sparta, and this continued to exist, though greatly depopulated, even after Guillaume de Villehardouin had in 1248-49 founded the fortress and city of Misithra, or Mistra, on a spur of Taygetus some three miles north-west of Sparta. This passed shortly afterwards into the hands of the Byzantines, who retained it until the Turks under Mohammed II. captured it in 1460. In 1687 it came into the possession of the Venetians, from whom it was wrested in 1715 by the Turks.

The Modern City.—In 1834, after the War of Independence, the modern town of Sparta was built on the ancient site from the designs of Baron Jochmus, and Mistra decayed until now it is almost deserted. Sparta is the capital of the prefecture (voués)

SPARTACUS, leader in the Gladiatorial War against Rome

SPARTACUS, leader in the Gladiatorial War against Rome (73-71 B.C.), a Thracian by birth. He served in the Roman army, but seems to have deserted and been sold as a slave. Destined for the arena, he, with some fellow gladiators, broke out of a training school at Capua and took refuge on Mt. Vesuvius (73 B.C.), where they were joined by other runaway slaves. They defeated two Roman forces in succession, overran most of southern Italy and ultimately were about 90,000 strong. Spartacus defeated both consuls of 72 and fought his way successfully toward the Alps. As the slaves refused to leave Italy, he returned to Lucania, hoping to cross to Sicily; but he was thwarted by the new Roman commander, M. Licinius Crassus, who had eight legions. His large army divided; the Gauls and Germans were defeated first, and Spartacus ultimately fell fighting in a pitched battle (71). Many slaves who escaped northward were cut to pieces by Pompey on his way home from Spain.

Spartacus was both competent and, apparently, humane. His reputation has suffered from the terror that his name inspired

throughout Italy.

BIBLIOGRAPHY.—The story has to be pieced together from the vague and somewhat discrepant accounts of Plutarch (Crassus, 8-11, Pompey, and somewhat discrepant accounts of Plutarch (Crassus, 8-11, 170mpey, 21), Appian (Bell. Civ.), 1, 116-120), Florus (ii, 8), Livy (Epit., 95-97) and the fragments of the Histories of Sallust, whose account seems to have been full and graphic. See T. Rice Holmes, The Roman Republic, i, pp. 135-161, 386-390 (Oxford, 1923); H. Last, in Cambridge Ancient History, ix, pp. 329-321 (1932).

SPARTANBURG, a city of South Carolina, U.S., the county

seat of Spartanburg county; in the northwestern part of the state,

on federal highways 29, 176 and 221.

It is served by the Charleston and Western Carolina, the Carolina, Clinchfield and Ohio, the Southern and the Piedmont and Northern (electric) railways, by air and bus lines. Pop. (1950) 36,795; (1940) 32,249 by the federal census, with an additional 20,000 in the immediate suburbs.

Spartanburg is 875 ft. above sea level, in the heart of the beautiful Piedmont section, a leading theatre of industrial development in the south, and is one of the large textile centres of the United

It is the seat of Wofford college for men (Methodist Episcopal; 1850), Converse college for women (1889) and the Spartanburg Junior college (1911), where students alternate weeks of classroom study with work in various stores and industries.

The city is a leading shipping centre of peaches, fresh tomatoes, pimiento peppers and grapes. Cotton is also produced in the

In 1947 the city adopted a commission-manager form of government. Spartanburg was founded in 1789 and incorporated as a city in 1831.

SPARTINA. A genus of grasses (Gramineae) belonging to the tribe Chlorideae. Of the seven or eight species, most are North American, where the Fox grass (S. patens) and Salt Thatch (S. alterniflora) are common on the salt marshes of New England. In Europe S. stricta occurs on the salt flats of southeast England, France, Portugal and the Adriatic. S. alterniflora has been known at Southampton from 1829, where it was probably introduced by shipping from America. The genus is remarkable for scribed as the woolsack, from the material with which it was

the sudden appearance of a new distinct form at Southampton in 1870, Spartina townsendii. This tall-growing and robust form has spread widely in recent times on the soft tidal muds of both sides of the English channel (Southampton water, Portsmouth, Poole harbour, etc., and in the Vire, Seine and other French rivers). Sparting townsendi is exceptional in colonizing soft mud previously bare, for the vigour of its spread and for its power of holding silt and raising the level of the mud. It is probably a hybrid between S. stricta and S. alterniflora. In 1924 it was introduced into the Netherlands and extensively planted on the bare mud of the Scheldt, in Zeeland and elsewhere, with a view to hastening the time when such ground could be banked (poldered) (F. W. O.) and used for agriculture.

SPASM: see CRAMP; MUSCLE AND MUSCULAR EXERCISE; NERVE

SPASMODICS, THE, a name given to a group of English poets in the '40s and '50s of the 19th century. It was first applied by W. E. Aytoun in Blackwood (May 1854) in a mock review of his own satire, Firmilian: a Spasmodic Tragedy (E. A. Poe had used the word "spasmodist" five years earlier). The writers usually classed as spasmodics are P. J. Bailey (Festus, 1839), Ernest Jones, the Chartist song-writer, Ebenezer Jones, also a Chartist (Songs of Sensation and Event, 1843), Sydney Dobell (The Roman, 1850; Balder, 1854) and Alexander Smith (A Life Drama, 1853; City Poems, 1857). But it would be difficult to exclude some of Mrs. Browning's early work (Seraphim, 1838; Drama of Exile, 1845), before she had assimilated her husband's influence, and Tennyson's Maud (1855) is in its violence, sentiment and frequent lapses of taste not far removed from the spasmodic manner. In the '40s the romantic impulse was exhausted and the Augustan notions of form discredited; but Tennyson and Browning had not risen to acknowledged ascendancy, and M. Arnold had not formulated the new canons of criticism. The interim was a time of false starts, of poets whose aspirations, excited by Byron and Shelley, were unrestrained by any tradition of style or any effectual contemporary criticism.

SPEAKER, the title given to the presiding officer in many of the legislatures which have taken their tradition from England. In the 13th century it became the practice to summon representatives of the counties and boroughs to attend the king "in his court in his council in his parliament." After the middle of the 14th century, if not before, the "commons" sat separately, and in 1377 we first learn of the existence of a "speaker" who presided over their deliberations and spoke for the commons when they were summoned to attend the king in parliament (i.e., in the house of lords). The speaker was appointed by the king, but on the nomination of the house of commons. From 1377 whenever there has been a parliament there has been a speaker. At the opening of parliament the king, or lords commissioners on his behalf, orders the commons "to repair to the place where you are to sit and there proceed to the choice of some proper person to be your speaker." The commons having done so, they attend upon the king or the lords commissioners, where the speaker-elect announces that the choice of "His majesty's most faithful commons" has fallen upon him and that he "submits himself with all humility for his majesty's gracious approbation." The king's approval having been expressed, the speaker not only "speaks" for the commons at the bar of the house of lords but also presides over their deliberations whenever he is present and they are not sitting in committee. When the house desires to discuss a matter privately. for instance the granting of supply to the king, the motion is made "that Mr. Speaker do now leave the chair." for the speaker is the king's representative. The term has, however, been generalized, and even the presiding officer of the house of lords, generally the lord chancellor, is often described, though inaccurately, as the speaker of that house.

In the house of lords the sovereign presides from the throne if present, but he is now never present except to read the king's speech at the beginning or the end of a session. In his absence the lord chancellor, or the lord keeper of the great seal if there is no lord chancellor, presides from a seat below the throne deformerly stuffed. The woolsack is technically outside the limits of the house, so that the lord chancellor or lord keeper need not be a peer In practice the lord chancellor is raised to the peerage, but it is not uncommon for him to preside before he receives his patent. The lord chancellor or lord keeper has none of the wide powers exercised by the speaker of the house of commons, for the house of lords decides its own procedure on a motion moved by a member of that house, and the lord chancellor's only function is to put the motion to the house and declare whether the house is content or not content. Also, he is an active member of the government and takes part in the proceedings of the house (if a peer) in that capacity He is invariably a lawyer and usually presides when the house is sitting for indicial business

Functions and Powers.-The speaker of the house of commons is not only the presiding officer but also the guardian of its powers, dignities, liberties and privileges. Immediately his election is confirmed by or on behalf of the king he lays claim, in the name and on behalf of the commons of the United Kingdom, "to all their ancient and undoubted rights and privileges, especially to freedom of speech in debate, to freedom from arrest, and to free access to his majesty whenever occasion shall require; and that the most favourable construction may be put upon all their proceedings." He has wide powers, not only by standing orders, but also by the practice of the house. His rulings on matters of procedure are accepted without question by the house and are recorded in the journals, where they become precedents for future decisions. Some decisions, such as those on the admissibility of questions, are taken outside the house and are recorded privately by the clerks at the table. On the basis of all these decisions, recorded for centuries, there has arisen a lex et consuetudo parliamenti described by Sir Erskine May, afterward clerk of the house of commons, in his Treatise on the Law, Privileges, Proceedings and Usage of Parliament (1st ed. 1844), which is kept up-to-date by successive clerks (14th ed. 1946, by Sir Gilbert Campion) and used as the standard work of reference.

Comparatively recent reforms in the procedure of the house, necessitated by the pressure of business, the development of a highly organized party system, the broadening of the electorate, and the growth of organized obstruction after the raising of the issue of home rule for Ireland, have added considerably to the speaker's powers. He may now accept a closure motion if he considers that it is not an abuse of the process of the house, select amendments from among those on the order paper (the "kangaroo"), and apply any "guillotine" motion that may be passed by the house for the closure of a series of debates by compartments. He also decides whether a motion for the adjournment of the house for the discussion of a "definite matter of urgent public importance" shall be put to the house. These are in addition to his ordinary power of deciding whether a bill, motion, question or observation is in order, whether a remark is "parliamentary," whether a discussion is relevant to the motion before the house, whether a question or a supplementary question shall be allowed, whether a financial resolution is necessary before or after a bill is introduced, etc. His influence is wider than even his wide powers would indicate, for a suggestion by the speaker as to the conduct of business is generally accepted by the house.

Modern Practice.—His enormous influence is due to the fact that the speaker makes every attempt to be completely impartial. In the 18th century the speaker was generally an active politician; and Henry Addington, for instance, moved from the chair to the treasury bench. Early in the 10th century, however, successive speakers made an attempt to reach impartiality, and the process was completed by Charles Shaw-Lefevre, who was speaker in the difficult period 1839-57, when party alignments were being drawn more strictly as the consequence of the first Reform act became clear. It is now the practice for the government of the day, after consulting the leaders of the opposition, to nominate a back-bencher who has taken no prominent part in political controversy and who is acceptable to all sections of the house. There was no opposition to any nomination between that of W. C. Gully in April 1895 and that of W. S. Morrison in Oct. 1951. The election is usually proposed by a back-bencher on the government

side and seconded by a back-bencher on the opposition side, the leader of the house and the leader of the opposition making the first congratulatory speeches after the election. It is also the practice in a new parliament for the late speaker to be re-elected if a member of the house and willing to serve, even if there has been a change of government in the meantime. It was formerly the practice for the late speaker not to be opposed in his constituency if he desired to stand again, but this practice was not followed by the Labour party in 1935 and 1945 on the ground that it prevented the constituency from expressing its views on the political questions of the day; and in 1950 Col D Clifton Brown was opposed by an Independent Liberal. The speaker has a salary of  $\frac{4}{5}$ ,000 a year, on his retirement he is offered a viscounty and provided with a pension by act of palliament

The speaker being thus as impartial as it is possible for a human being to be, he is able to guide the proceedings of the house even when controversy is at its height, and the prestige of the house depends in very large measure on the ability of its speaker not merely to control but also to lead. In particular, he is able to secure on the one hand that government shall not be obstructed and on the other hand that every point of view shall be adequately expressed. The small minority, such as the solitary Communist member in the parliament of 1935-45; is in fact given better opportunities than the back-benchers on the government side, simply because it represents an unpopular point of view. The speaker being impartial, he can also be used to preside over conferences of party representatives in which agreement between the parties is desirable, such as proposals for changes in the franchise or in the distribution of seats. Thus, the Representation of the People act, 1918, was the result of a conference over which J. W. Lowther (speaker 1995-21) presided, and the changes of 1945 were recommended by a conference of which Speaker Clifton Brown was the president

The house on its side does everything possible to exalt the office of speaker. No member may stand while the speaker is on his feet or pass between the speaker and the house. All observations must be addressed to the speaker and not to the house. The speaker's procession on its way to the house is a daily ceremony. Outside the house he speaker used to be the "first commoner," but since 1919 he has ranked after the prime minister and the lord president of the council, though before all peers of the realm except the two archbishops. His carriage is still entitled to drive down the centre of the Mall, passing all other carriages, because of the privilege of the house to "free access to his majesty whenever occasion shall require"

to his majesty whenever occasion shall require" BIBLIOGRAPHY.—J. A. Manning, Lives of the Speakers (London, 1850), E. and A. G. Porritt, The Unreformed House of Commons, 2 vol. ## SPEAKER OF THE HOUSE OF REPRESENTATIVES

The United States constitution provides that "the House of Representatives shall choose their Speaker and other officers . . ." In creating this office its authors had in mind the speaker in the colonial assemblies who had been both a presiding officer and a political leader. Early expectations were later realized, for U.S. speakers after 1789 have been both parliamentary and political personalities.

The speaker of the house holds an office of dignity and honour, of great power and influence. Usage dictates that he shall always be a member of the house; and as such the constitution requires him to be seven years a citizen and at least 25 years of age. Candidates for the office are nominated by party caucuses prior to the convening of each congress and the speaker is customarily elected by the house on the opening day, barring a protracted contest. Competition for the place is keen and the final choice is influenced by knowledge of parliamentary procedure, previous legislative experience, sectional claims, private interests, personal qualities and political considerations.

History of Office.—During the first 83 congresses (1789–1953) the speakership was held by 47 men (including speakers bro tem), of whom 14 had previously been speakers of the state assemblies and 24 others had served in state legislatures. Only nine of the speakers were without any prior state legislature experience, and of these none held the office prior to at least his fourth term in the national legislature. Three speakers were elected to the office in their first term in the house of representatives: Frederick A. C. Muhlenberg, the first speaker, who had been speaker of the Pennsylvania house and a delegate to the constitutional convention; Henry Clay, who had served several terms in the Kentucky legislature as member and speaker and had been a U.S. senator; and William Pennington, who had once served in the New Jersey assembly. With the exception of these three, every speaker had had prior service in congress, ranging from 1 to 14 terms.

During the 19th century prior congressional service ranged from one to seven terms. Long experience in the house is a modern condition of election. Up to 1896, when Mary P. Follett published her pioneer study of the office, the average length of service of speakers as such had been three years; from 1896 to 1953 the average increased to five

vears

Many famous men have occupied the speakership after Muhlenberg, including Clay, Stevenson, Polk, Colfax, Blaine, Reed, Cannon, Clark, Gillett, Longworth and Rayburn. Henry Clay and Sam Rayburn hold the record for the longest service—six terms. Five of the six terms served by Clay, the only representative whose entire career in the house was spent in the chair, were consecutive Prior to the 83rd congress, Stevenson, Cannon and Clark had served four terms each, Macon, Colfax, Blaine, Randall, Carlisle, Reed, Gillett, Longworth and Bankhead each had three terms in the chair.

Of the first 47 speakers, 9 came from New England, 9 from middle Atlantic states, 70 from the middle west and 19 from the south. Southern influence predominates in the organization of the Democratic party, for "the soild south" has been prevailingly Democratic after the Civil War and repeatedly has re-elected the same congressmen. Southern members thus acquire seniority and power in party councils Every Democratic speaker (except Rainey of Illnois) after 1865 had been,

up to the soth congress, a southerner.

Powers and Duties.—The parliamentary powers and duties of the speaker stem from four sources: the constitution and laws of the United States, the rules of the house, previous decisions of the char, and general parliamentary law. He presides at sessions of the house and opens and closes its sittings, acts as its mouthpiece and representative and authenticates documents, announces the order of business, puts ougstions and announces the vote.

He also decides questions of order, can prevent obstruction of house business, refers bills and reports to the proper committees or calendars, chooses speakers pro tempore, and appoints the chairmen of committees of the whole. These duties he performs impartially like the speaker of the house of commons, as evidenced by the fact that his decisions are rarely appealed. He also enjoys the privileges of an ordinary member of the house of orthe house of the ho

Prior to 1910 the speaker also possessed important political powers. He appointed, deposed and demoted the chairmen and members of committees; he served as chairman of the committee on rules, which

<sup>\*&</sup>quot;Terms served prior" does not include the term elected speaker except for the ½ years as noted for 45 and 45.

Number in parentheses indicates the number of consecutive terms immediately preceding election as speaker. All are consecutive unless so indicated.

enabled him to control the business of the house; and he recognized or refused to recognize members claiming the floor. These powers, gradually evolved by strong speakers like Reed and Cannon, reached a peak of perfection and omnipotence during the latter's regime So dictatorial and despotic, indeed, did Speaker Cannon become that the house rebelled, and in March 1910 a coalition of Democrats and insurgent Republicans succeeded in drastically curtailing his powers. They removed the speaker from the rules committee, deprived him of the power to appoint the standing committees of the house and restricted his right of recognition. After the revolution of 1910-11 the speaker was more the servant than the master of the house.

These reforms, however, were less revolutionary than they then seemed. Prior to 1910 the speaker controlled the house in collaboration with a cotie of trusted party leutenants "Nowadays the leadership of the house is in commission, with the membership of the commission

more or less fluctuating and shadowy."

In 1910 the speaker was removed from the committee on rules, but he sits today on the unofficial steering committee which meets in his office and determines party strategy. In the March revolution he lost his power of appointing the standing committees, but he retained the power of appointing house conferees, the chairman of the committee of the whole and select committees. His power of recognition was reduced, but he still has a discretionary power of recognition over motions to suspend the rules and on days other than consent calendar days.

Place in Political System.—The Presidential Succession act of 1047 ranked the speakership next to the presidency and vice-presidency. Cannon considered the speakership a more important and powerful office than the presidency itself. Relations between speakers and presidents have fluctuated between rivalry and harmony through the years. Depending on the political complexion of the two offices, the speaker bas been leader either of the administration or opposition forces in the house. During periods of congressional supremacy the chair has overshadowed the White House, while popular-leader presidents from Thomas Jefferson to Franklin D. Roosevelt have dominated congress. Within their parties Reed and McKinley, Clark and Wilson, were bitter rivals who seldom came in contact. But relations between the second Roosevelt and his party speakers were cordial and frequent. Despite the reduction in his powers, the speaker continues to be at once the presiding officer and titular leader of his party in the lower chamber, a private member and the most influential man in the house of representatives.

BIRLIOGRAPHY.—Mary P. Follett, The Speaker of the House of Representatives (1896); George Rothwell Brown, The Leadership of Congress (1922); Paul DeWitt Hasbrouck, Party Government in the House of Representatives (1927); Chang-Wei Chiu, The Speaker the House of Representatives Since 1896 (1928). **SPEARMINT** (Mentha spicata), a species of mint (q.v.) used for culinary and other purposes, distinguished by its smooth sessile leaves and tapering flower spikes. The flowers are pale blue, and appear from July to September. Spearmint was introduced into the United States where it became widely naturalized in moist waste grounds. The volatile oil, from spearmint is also used as a medicine. (See MINT; PEPPERMINT.)

SPECIE POINT: see Exchange, Foreign: Gold Points.

SPECIES. The nature of species is a question of considerable importance in general biology and the species is regularly employed as a classificatory unit in systematic botany, zoology and mineralogy. The word "species" has, however, an important history outside those sciences. It was the Latin equivalent of the Greek This meant primarily shape or visible form, but was extended to cover the sensible character of things generally, and also the intelligible. For the former use compare the term "sensible species" or characters in things perceived, because reproduced in the organs of sense. To the supposition that we see these reproductions is partly due the doctrine that the mind perceives directly only its own ideas. So Locke says (Essay Concerning Human Understanding, Introduction, § 8) that he uses the word "idea" to express whatever is meant by phantasm, notion, "species." As intelligible character, eloos or species was the common essence of individuals or instances, as we say, of the same kind. As such it was an object of thought, not of sense; universal, not individual: and, unlike its instances, exempt from generation and decay. Its relation to its instances (which may be compared to that of a law to the events exemplifying it) was a subject of dispute both in Greek and scholastic philosophy. There were also disputes about the relation of species to their common genus, of which they are determinations (so that Aristotle compared the relation of genus to species with that of matter to form), and to the properties connected and accidents conjoined with their specific nature in instances of a species. Boetius' Latin translation 176 SPECIES

of the Isagoge (Introduction) written by Porphyry (born AD. 232) to the Categories of (or ascribed to) Aristotle made these questions familiar long before the revival of Aristotelian learning in the west. In particular it was disputed whether species and genera were anything real independently of our minds, or only common names, or else notions of ours, the products of our classifying activity. A settlement of these questions is not necessary to the work of the systematic biologist; but they must be faced if we are really to understand what we mean by the evolution of species; for this evolution is a process of which no persisting material thing is the subject.

#### BIOLOGICAL SPECIES

The concept of species as a kind of animal or plant is an old one in biological literature. Aristotle (384-322 B.C.) used the term for groups of organisms with common characters and these in turn he subdivided into more species. John Ray (1627-1705) is usually given the credit for using the term for groups with mutual fertility. C. Linné (see LINNAEUS) (1707-1778) established a system of binomial nomenclature universally used in the 20th century. Each organism was classified as a member of a species and each species was included in a higher taxonomic group, the genus. The genera were also classified in still higher taxonomic categories, but the binomial name consisted of the names of the genus and the species together. International congresses of botany and zoology respectively formulate, administer and interpret the international rules of botanical nomenclature and the international rules of zoological nomenclature. The basic principle used for natural classification is homology (q,v). In early modern times homology was a vague concept applied roughly to apparent similarities of structure. During the 20th century, however, genetics, embryology, ecology and evolutionary analysis came to place a firm scientific foundation under the concept of homology with consequent clarification, correction and verification of systematic

C. Linné first believed in the fixity of species but later in his life suggested that the genus constituted the ancestral species at the time of creation, and that derived species subsequently multiplied by means of hybrid generation or intercrossing between species. During the 19th century, particularly through the work of J. B. P. Lamarck (1744–1829) and Charles Darwin (1809–1882), the theory of the evolution of species was accepted by the large majority of biologists (1808 EVOLUTION, ORGANIC).

The importance of isolation in the origin of species was emphasized by M. Wagner (1813–1887) and J. T. Gulick (1823–1932). Modern genetic theory, initiated by Johann Gregor Mendel (1822–1884) by means of his investigations of domestic varieties of plants, was applied to both plants and animals in the early zoth century. Mendelian genetics of individuals led gradually to the establishment of the science of population genetics during the third and fourth decades of the zoth century. Population genetics substantiated the concept of the biological species and greatly improved the understanding of evolutionary processes.

proved the understanding of evolutionary processes.

The species is recognized as a prime biological unit with objective criteria. More than 1,000,000 species of plants and animals had been named by mid-20th century and probably at least twice this number would ultimately be recognized when the knowledge of the world faunas and floras approaches completion. The concept of the species is of great importance in both theoretical and applied biology and played a prime part in the development of evolutionary theory and principles. Much controversy arose concerning the basic characteristics of the biological species.

There are almost as many definitions of the species as there are biologists who have attempted to condense the major aspects of the concept. Some have thought that the species was wholly a subjective category and was merely a figment of the mind of the systematist. Others have emphasized the visible anatomical distinctions without searching for the basic principles underlying structural differences and similarities. Still others have confined the concept to the sexual interbreeding population. Slowly the operational factors producing the species under natural conditions were recognized and incorporated into the definition. It became known that numerous factors operate to produce species, and that these may vary in intensity and in time during the origin of the same or different species. The species shares the dynamic complexity of other basic biological units including the

gene, the cell and the individual organism, all of which present difficulties of precise definition.

A brief definition that includes the most generally recognized criteria of the biological species was given by A. E. Emerson in 1945. a species is an evolved or evolving, genetically distinctive, reproductively isolated, natural population. All of these attributes are necessary, and no others would seem to be essential. Each attribute is discussed separately in the following paragraphs.

Since the establishment of the principle of evolutionary change, species have been considered to be dynamic entities and not fixed or static. Evolutionary characterization is therefore necessary in the definition. Demancation sometimes is somewhat arbitrary when transitional stages are encountered, but true evolutionary gradations are not often found, so that ancient continuities are seldom observable between living species and the palaeantological record seldom bridges the gaps between species categories. Although nomenclature is easier when the ancient continuities are unknown, cases in which intergradations between species can be directly observed offer an opportunity for a more exacting study of the processes of speciation, and analytical biologists seek such material for investigation. Also the early stages in species divergence that have not progressed to the point of complete species division enable the scientists to analyze the dynamic factors more exactly and are consequently sought.

Genetic distinction seems to be the common denominator for all valid qualitative or quantitative species characters including cytological, physiological, embryological, ethological, ecological, and morphological characters. Taxonomists, of course, seldom can experimentally investigate the genetics of the species they study and must rely upon structural or colour indications of genetic relationship. Anatomy and pigmentation often are sensitive to small genetic influences that are not easily detected by other techniques of observation. Heredity may be inferred through demonstrated germinal continuity in populations and through the experimentally established basis of similar characters in investigated organisms. Hybrids and intergrading populations give some genetic information. If striking structural characters are not correlated with genetic distinctions of reproductively isolated natural populations, the taxonomist usually does not use them for species separation and will correct errors that have been committed in ignorance of the genetic implications For example, structural changes produced by various conditions at the time of growth, by differences in stages of development, by sexual dimorphism, by castes of social insects and by various types of polymorphism do not neet the criteria of genetic distinction and reproductive isolation. On the other hand, slight genetic distinction of natural populations that are reproductively isolated may be used for species separation, while gross genetic differences of individuals or of only partially isolated populations are not valid for species distinction.

Reproductive isolation (W. C. Allee et al, 1949) or lack of gene flow between populations, may result from chronological separation, spatial between populations, may result from chronological separation, spatial separation, topographical or geographical barriers to dispersal, abattat or ecological restrictions, cyclic differences in breeding periods, mechanical inability to crossbreed, psychological or ethological barriers to interbreeding, physiological barriers to fertilization, genetic unbalance preventing fusion, inviability of hybrids, hybrid sterility, and selective elimination of hybrids. Regardless of the exact type of isolation or the combination of isolating factors, anything that prevents genes from moring from one population to another has profound evolutionary con-sequences. Reproductive isolation is the dividing factor in the branching of the phylogenetic tree, and the two populations thus deprived of gene exchange will tend to drift apart through changes in gene incidence and gene or chromosome mutation. Because of its effect upon inbreeding, reproductive isolation also influences gene and character fixation. As most taxonomic characters are the result of complex genetic patterns rather than single genes or chromosomes, the consolidation of these patterns and their transmission as systems becomes a necessity for further adaptive evolution. Fixation of complex genetic patterns for intriner adaptive evolution. Fixation of complex genetic patterns is a primary consequence of reproductive isolation. Reproductive isolation may take place gradually and give rise to many subdivisions of the species population before speciation is completed. Theoretically the point of species origin is the moment that genetically distinctive natural populations cease gene exchange. Practically it may not be possible to recognize this point in instances of contemporary speciation. However, the large majority of valid species have been isolated for thousands or millions of years, so that it is a rare case that presents difficulties when an abundance of objective arctices has been one of the contemporary. difficulties when an abundance of objective evidence has been accumulated.

An important group of biologists including Theodosius Dobzhansky (1951) and E. Mayr (1942) excluded extrinsic barriers to gene finding (geographical or ecological) in their definitions of reproductive isolation as applied to species and confined the concept to examples separated by intrinsic barriers (psychological, genetic and physiological). They did not give full species rank to genetically divergent natural populations completely lacking gene exchange, but which have not lost their potential ability to interbreed if the extrinsic barriers are removed. Inasmuch as it is often impossible to judge the potentialities of interbreeding under natural conditions, these biologists had to rely upon a rough correlation between interbreeding potentialities and degrees of taxonomic divergence. When two related species occupy the same ter-

ritory (sympatric species) and no intergrades occur between them, biologists may assume an intrinsic barrier to gene flow Such an assumption is much less warranted in the cases of closely related but geographically separated distinctive populations (allopatric species), however, and there is a resulting confusion of taxonomic status of numerous groups One school of taxonomists may refer certain popula-tions to full species rank, while the other school will treat the same

populations as subspecies.

If reproductive isolation includes the extrinsic barriers to gene flow, it is possible that species that have not evolved intrinsic barriers may ultimately interbreed with the occasional breakdown of temporary extrinsic barriers. The hybrid origin of a species from two pre-existing species is thereby a possibility. The school of biologists that confine reproductive isolation between species to intrinsic prevention of gene flow only do not recognize full species status for the exof gene how only do not recognize in species saids for the possibility of hybrid origin of species except in special cases in which intrinsic barriers are also broken down (allopolyploidy in plants). In spite of these differences of opinion of the exact definition of reproductive these ametrices of opinion of the exact terminon of reproductive isolation with consequent confusion over the taxonomic status of some natural populations, the large majority of plant and animal species prove to be intrinsically isolated Therefore there is common agree-ment among biologists concerning most species limitations together with the criteria for the recognition of the species category

The final characterization of the species is that it constitutes a natural population. The population is integrated by means of genetic continuity through reproduction, and it may also be integrated through sexual reproduction and various other adaptations for attraction and interaction between individuals of the same species. The species population is often subdivided into many subpopulations, but the larger species population is a real entity with a definite boundary. Differences in fundamental biological interactions occur within the species population in contrast with the biological interactions between species populations. The species is generally conceived to result from natural evolution. Artificial populations compounded by man through domesevolution. Artificia populations compounded by man intologic norma-tication or for scientific investigation are not given species rank even when they are genetically distinctive and reproductively isolated popu-lations. Under natural conditions such man-produced populations would seldom maintain their genetic distinctiveness even if they were able to survive. The domestic dog is classified as a full species, but the separate breeds are not.

separate breeds are not.

Numerous infraspecies categories relate to variations in the qualitative or quantitative attributes of the species. Each term places emphasis upon particular aspects of the species concept (G. du Rietz, 1930)

Some of the terms are defined below and are useful in the

study of speciation mechanisms

Sexual Species .- This term is used for species that possess sexual adaptations and interfertility among the component individuals Sex-

adaptations and interfertility among the component individuals Sexual recombination of genetic elements greatly increases genetic variability. Many definitions of the species confine the concept to the sexually interbreeding population (Dobxhansky, 1951).

ASEXUAL Species.—These are species that have never evolved sexual fusion or have secondarily lost the ability to intercross. All reproduction is confined to division, parthenogenesis, apomixis, or vegetative reproduction. This species category would include the primary asexual bacteria and many single-celled organisms and would also include the secondarily asexual parthenogenetic animals and apomictic plants (G. L Stebbins, 1950). In asexual organisms, reproductive isolation between individuals of the same generation is absolute, and genetic continuity is only through descent. In some instances taxonomic distinction is maintained for periods comparable to the maintained of taxonomic pattern in sexual species (species of flagellate onomic distinction is maintained for periods comparable to the main-tenance of taxonomic pattern in sexual species (species of flagellate protozoans inhabiting the hind gut of termites). In other instances, taxonomic distinction may vary over short periods of time and the species category is difficult to apply (virulent and nonvirulent strains of viruses and nutritive strains of bacteria).

Subspecies.—This category is a subdivision of a sexual species with all the attributes of the species experient that reproductive schaltion is

all the attributes of the species except that reproductive isolation is partial rather than complete. Subspecies are given trinomial names by taxonomists and are recognized as constituting a valid category in the international rules of nomenclature. A species subdivided into subspecies or races is called a polytypic species.

Race.—This commonly used term is not separated by definition from

the subspecies. However, it is either used as a synonym for the subspecies category or is given a rank below that of the subspecies, presumably because the degree of reproductive isolation is smaller than

Sumany because the degree of reproductive isolation is smaller than that separating the subspecies.

Deme.—G. S. Carter (1951) defined a deme as a communal interbreeding population within a species either wholly or partially isolated from other demes.

Supraspecies.—This term was used by J. Huxley (1939) for a collection of groups or subspecies which replace each other geographically or physiologically and in which the extremities only have evolved intrinsic isolation. Comecting groups between the extremities interbreed and intergrade. There are several known cases among snakes, birds and mammals in which intersterility occurs among some of the subspecies within the species.

Coenospecies .- This term was first used by G. Turesson (1922) for the sum total of possible combinations of a genotype compound as seen particularly through cultivation under artificial conditions The term has also been used to include groups of species separated only by ex-

tinuc barriers to gene flow.

Ecospecies.—G Turesson (1022) used this term for the species as realized in nature under the limitations imposed by the natural environment. It emphasizes the limitations of potential variation produced

by natural selection

by hatural selection

Biotype.—This term is used for a population of individuals with
identical genotypical constitution under similar conditions. Biotypes
are usually limited to asexual species or to populations within a sexual
species that result from asexual reproduction from a single individual.

species that result from ascutal reproduction from a single individual. Parallel mutation may possibly account for some biotypes.

Clone.—A clone refers to a group descended from a single individual without sexual combination. The individuals are presumably genotypically identical or isogenic. The term overlaps somewhat with

the hintyne

-G C Robson and O W. Richards (1936) adopted this Lineage. term for a racial complex of several lines of descent forming a meshed

network of evolution within the species

Variety.—This term is used with somewhat different meanings by different authors J Bequaert (1919) used the category for individuals or small groups of individuals that varied in a describable way from or small groups of individuals that varied in a describable way from the typical individuals in the species. Varieties may be considered somewhat distinctive groups that fall within the range of species variation as a whole but do not necessarily have geographical or ecological correlations.

Cline.—J. Huxley (1939, 1942) introduced this term for a character gradient within a group—usually within a species

Numerous subdivisions of clines are named when there is a correlation with special factors. Ecoclines are correlated with ecological gradients. Geoclines are correlated with geographical gradients. Taxochnes are correlated are correlated with geographical gradients. Taxonomic gradations associated with hybridization. Chronoclines are correlated with time in palaeontological sequences. Ontoclines are gradations in the appearance of characters during the life cycle of individuals.

Ecotype.—G. Turesson (1922) introduced this term for the geno-typical response by portions of species populations to a given type of habitat. The ecotype is essentially an ecological subspecies and emphasizes the role of natural selection upon genetic constitution.

Ecophene.—This term was also used by Turesson (1922) reaction type to extreme environmental factors without genetic distinctions. Ecophenes are illustrated by climatic modifications at the tree line, by shade types of plants that normally range through a variety of light conditions, and by temperature influences on growth at different latitudes.

Physiological Species or Races.—These terms are used to dis-tinguish species or subdivisions of a species that are recognized by physiological characters rather than structural characters. Genetic distinction is usually manifest in structural or anatomical characters, but gene patterns may effect physiological characters without pro-ducing sufficient anatomical effects to be recognized. The term "bio-logical race" is essentially synonymous with "physiological race" Incipient Species.—This term is used for a diverging partially

isolated population that may become a species when isolation becomes

complete.

Complete.

SPECIFIC GRAVITY is the ratio between the density (mass per unit volume) of a body and the density of some substance assumed as a standard. For liquids and solids the standard is distilled water at 4° C. In the centimetre-gram-second system of units the numerical values for the density and the specific gravity of any substance are the same. In the English system the density of water is 62.4 lb. per cubic foot, while its specific gravity is still unity. (See Physics, Articles on.)

SPECIFIC PERFORMANCE, an equitable doctrine under which a court of equity, in certain exceptional cases where the normal legal remedy, ie., damages, would not be a sufficient compensation, orders by a defaulting party a specific or actual performance of the thing which he had contracted to do. The court as a general rule will refuse this relief where it would be unable to superintend or enforce the execution of its judgment. Specific performance is usually confined to executory agreements, ie., a conveyance or a lease of land, it is not usually enforced in the cases of personal acts or in those of contracts for personal service The doctrine of specific performance in the United States follows very largely that of England.

SPECTACLES, a name given to a pair of focused corrective ophthalmic lenses supported on the nose by a frame or mounting and equipped with side pieces called bows or temples that are held in place by the ears. Spectacles differ from other forms of ophthalmic corrections by their construction. For instance, eyeglasses are a pair of corrective lenses supported on the nose by a mechanical bridge. The pince-nez falls into this classification. The oxford is a special eyeglass that is made in a folding and nonfolding form with a spring to make the bridge adhere to the nose. It is commonly carried on a light chain or ribbon which is worn around the neck and is used for an occasional or short interval of wear. A lorgnette is a pair of lenses held in a frame that is attached to a long handle. A lorgnon is similar to the lorgnette except it has a short handle which serves as a carrying case when the device is folded. To spectacles which are used primarily for ocular protection the term goggles is sometimes applied. However, goggles are an optical device which cover the eyes with an optical medium in front and with a shield on the sides and are attached to the head by bands, cap or hood. The tendency is to call all corrective ophthalmic lenses with their supporting equipment, eyeglasses.

The early history of spectacles is not clear (See Thomas Young Oration, Trans. Optical Soc., 1923-24, no. 2; also 1926-27, no. 3.) In 1266 Roger Bacon magnified writing by placing a segment of a sphere of glass on a book. The first reasonably dated evidence of spectacles is given in a portrait of Cardinal Ugone in a fresco painted in 1352 in a church at Treviso, showing two framed lenses with their handles liveted together and fixed over the eyes

The advent of the printed book created the need for spectacles. In north Italy and south Germany where the glass workers lived, the spectacle trade flourished during the 16th century. The optical trade spread rapidly through Europe and in 1629 Charles I granted a charter to the Spectacle Makers guild. About 1760 bifocals were devised by Benjamin Franklin. Not until 1900 were cylindrical lenses commonly used.

Short sight, called myopia, is generally caused by an abnormally long anteroposterior axis or a marked refractive power of the optical system of the eye. In the case of the short-sighted person, parallel rays of light come to a focus in front of the retina. A concave lens of proper curvature diverges the rays so that they meet at the retina. The optical correction gives good distant vision and the accommodative power of the crystalline lens adjusts for near vision. In high myopia the inconveniently heavy lens may be ground flat at the edge to reduce the weight.

Far sight, or hypermetropia, is generally caused by a short antero-posterior axis of the eye. It is a stage in the early normal development of the eye and is a common defect. Parallel rays of light come to a fo-cus behind the retina but a convex lens converges the rays so that they will focus on the retina. The far-sighted person always accommodates for distant vision. In rare congenitally defective eyes and in eyes after the removal of cataract, a high degree of hypermetropia occurs. Carefully adjusted heavy convex lenses are then necessary for good vision with the least amount of distortion. A lens of light weight made with a flat periphery and a convex centre is used occasionally. Contact glasses in place of a convex lens are suitable if they are tolerated. In astignatism the refractive power of the eye is more marked in one meridian than in the others. The correction is made with a convex

one meridian than in the others. The correction is made with a convex or concave cylindrical lens or with a similar cylindrical lens combined with a sphere.

Presbyopia is a condition occurring with normal eyes after the age of 40 to 45 years when the power of accommodation is sufficiently decreased to cause blurring of the near vision. It affects the reading range of vision with little or no change in the distant vision. Convex reading spectacles to correct for the loss of accommodation are prescribed, Blicoal spectacles are also a marked visual aid. The upper part of the lens is used for far vision and the lower part for near vision. The lens may be made of fused or cemented lenses. The fused bifocal lens is constructed in many forms so that advantage of various optical properties of glass are made manifest. In advanced presbyopia, trifocal lenses take care of the intermediate distance between the distant and near visual range. Tetrafocals are used by presbyopic draftsmen and artists requiring a fourth area of the lens which has a very short focus so that objects may be held close to the eye. Pulpit spectacles

have only half-moon shaped lenses as a visual aid in presbyopia.

Glass prisms or decentred lenses are employed if the visual axes of the eye are abnormal or if the external ocular muscles and accommodation are not in harmony Prisms are also used as a means of exercising the external ocular muscles Lenses with horizontal silvered prisms ar made for reading in bed

Spectacles are of service in filtering out the undesired part of the spectrum Dark or coloured lenses decrease the amount of glare and They also help diminish the photophobia of irritable or dises. With dark glasses the vision in cases with certain kilote eased eyes. of central cataracts may be increased by allowing the pupil to dilate. Lenses with different colours are necessary to see anaglyphs stereoscopically and are used in this manner as a device to exercise squinting eyes. Coloured lenses are used to detect camouflage, in cheating in card games, for testing malingerers and in ophthalmic tests such as for

diplopia Red lenses maintain dark adaptation of radiologists, roentgenologists, night aviators and photographers

Lenses absorbing ultra-violet light are made for skiers, aviators, polar explorers, mountain climbers, gas, electric and atomic welders, and persons who are exposed to ultra-violet light as a medual treatment. Lenses opaque to infra-red light prevent damage to the eyes of furnace workers and metal processors. Didymium glass increases the visual acuity of glass blowers by masking the sodium spectra. Lenses absorbing the visible light of short wave lengths are employed by aviators, sailors, sportsmen and gunners to overcome atmospheric haze Lead glass absorbs radiation from roentgen rays and radium.

Aniseikonia, the inequality of the size and shape of the two ocular Amberkonia, the inequality of the size and snape of the two comminges in binocular vision, may be a cause of visual discomfort. The specially designed corrective lens known as an iseikonic lens is a doublet with an air space between the two parts which may be adjusted to change the size of the image without changing the focus.

Telescopic spectacles with a pair of short-barrelled Galilean telescopes in place of the single lenses aid in low vision. The Galilean telescope is also modified by using a contact glass as the near lens and the lens in the spectacle as the far lens. Another kind of spectacle has longer, narrower barrelled telescopes placed in front of the lenses to serve as a loupe. The simple loupe has a pair of prismatic convex lenses placed before the spectacle frame as a visual aid in stereoscopic vision of near objects.

Spectacles are also devised to give ocular protection against me-chanical injury. The optical material may be surface-hardened glass, plastic, laminated glass and plastic, or made of metal or other material slotted or otherwise perforated for vision. Peripheral lateral shields of solid or perforated material may be employed to guard against ocular contact with solid, liquid or gas, or materials causing allergies.

Other types of spectacles are also devised for special purposes. frames may hold a prosthesis, or artificial part, of the eye, orbit or face. Crutch spectacles elevate a drooping paralytic upper lid. Pinhole spectacles tend to limit the voluntary movement of the eyes and in this way prevent mechanical injury after an operation. They also serve as a means to check the refractive correction of the eye Frosted lenses help in overcoming diplopia. Molecularly coated lenses decrease the annoying reflections of glass in myopia. Lenses covered with coloidal metal act as light shields against infra-red light. Polaroid lenses londar metal act as ingin sinedas against inner-tea fight. To allold charles hold a film of submicroscopic crystals of herapathite, all oriented in the same direction, which transmit plane polarized light and thus tent to eliminate reflections and scattered light. They are also used to discover malingerers Divers' spectacles are devised for seeing under water. The lenses consist of a pair of two meniscus lenses separated by a biconcave air space. Spectacles consisting of a flat metal frame holding a sheet of red plastic are spiked to the head of chickens with abnormal appetites to prevent them from seeing blood and egg yolk.

abnormal appetites to brevent unit from some second repetition of the Britiography.—H. H. Emsley, Visual Optics (London, 1936); L. Laurance and H. O. Wood, Visual Optics and Sight Testing, 4th ed. (Chicago and London, 1936), General and Practical Optics, 4th rev. ed. (Chicago, 1022). (A. C. Ke.) (Chicago, 1932).

SPECTROHELIOGRAPH, an instrument for photographing the sun with monochromatic light. In its simplest form it consists of a direct-vision spectroscope, having an adjustable slit (called "camera slit" or "second slit"), instead of an eyepiece, in the focal plane of the observing telescope. This slit is set in a position such that it transmits a single line of the spectrum; e.g., the K line of calcium. A fixed image of the sun is formed on the collimator slit of this spectroscope, and a photographic plate, with its plane parallel to the plane of the solar image, is mounted almost in contact with the camera slit. The spectroscope is then moved parallel to itself, admitting to the collimator slit light from all parts of the sun's disk. Thus a monochromatic image of the sun, formed of a great number of successive images of the spectral line employed, will be built up on the plate. As the only light permitted to reach the plate is that of the calcium line, the resulting image will represent the distribution of calcium vapour in the sun's atmosphere. The calcium clouds, or flocculi, thus recorded are invisible to the eye, and are not shown on direct solar photo-

BY COURTESY OF PROFESSOR G. E. HALE, MOUNT WILSON OBSERVATORY

# HYDROGEN WHIRLS IN THE SUN

These hydrogen whirls surrounding a large bipolar sun spot were photographed at the Mount Wilson Observatory of the Carnegle Institution of Washington, with the 13-ft, spectroheliograph, Aug. 30, 1924. Photographs of the hydrogen layers of the sun's atmosphere show that sun spots are vortical in nature and that their movement may be clockwise or anti-clockwise.

graphs taken in the ordinary way. These, on account of the brilliant reversals of the H and K lines to which they give rise, and the protection to the plate afforded by the diffuse dark bands in which these bright lines occur, are easily photographed with a spectroheliograph of low dispersion. In the case of narrower lines, however, higher dispersion is required to prevent the light of the continuous spectrum on either side of the dark line from blotting out the monochromatic image.

A five foot spectroheliograph which gives excellent results with the lines of calcium, hydrogen and iron has been used since 1905 in conjunction with the Snow (horizontal) and 6oft, tower telescopes of the Mt. Wilson Solar observatory. It was constructed in the observatory instrument shop in Pasadena. The instrument consists of a heavy cast-iron platform mounted on four steel balls which run in V guides of hardened steel. Most of the weight of the instrument is floated on mercury contained in three troughs which form part of the cast-iron base. The platform carries the two slits, the collimator and camera objectives and the prismtrain. An image of the sun, about 6-7in, in diameter, is formed by the telescope on the collimator slit. The collimator slit is long enough (81 in.) to extend entirely across the solar image and across such prominences of ordinary height as may happen to lie at the extremities of a vertical diameter. After passing through the slit the diverging rays fall upon the 8in, collimator objective which is constructed in the manner of a portrait lens in order to give a sharp field of sufficient diameter to include the entire solar image. The rays, rendered parallel by the collimator objective, meet a plane mirror made of silvered glass, which reflects them to the two prisms. These are of dense flint-glass (Schott 0-102), and each has a refracting angle of 63° 29'. Their width and height are sufficient to transmit (at the position of minimum deviation) the entire beam received from the collimator. A grating, ruled on speculum metal with about 15,000 lines per inch, is substituted for the mirror when higher dispersion is required. After being deviated 180° from the original direction, the dispersed rays fall on the camera objective, which is exactly similar to the collimator objective. This forms an image of the solar spectrum in its focal plane on the camera slit. Beyond the camera slit, and almost in contact with it, the photographic platecarrier is mounted on a fixed support. In order to bring a spectral line upon the camera slit, the slit is widely opened and the plane mirror is rotated until it is possible to see the line. A cross-hair, in the focal plane of an eyepiece, is then moved horizontally until it coincides with the line in question. The slit is narrowed down to the desired width, and moved as a whole by a micrometer screw until it coincides with the cross-hair. The eyepiece is removed and the photographic plate placed in position. An electric motor, belted to a screw connected with the spectroheliograph, is then started. (Two alternative screws, of different pitch, are provided to give different speeds.) The screw moves the spectroheliograph at a uniform rate across the fixed solar image. Thus a monochromatic image of the sun is built up on the fixed photographic plate.

The spectroheliograph, originally designed for photographing only the solar prominences, disclosed, in its first application by Hale at the Kenwood observatory (Chicago, 1891, 1892), a new and unexplored region of the sun's atmosphere. Photographs of the solar disk, taken with the H or K line, showed extensive luminous clouds (flocculi) of calcium vapour, vastly greater in area than the sunspots. About this time Deslandres introduced at the Paris observatory, the velocity spectrograph, which permits the motion in the line of sight of the calcium vapour at various levels to be measured on photographs of the H or K line in successive sections of the sun. By setting the camera slit of a spectroheliograph so as to admit to the photographic plate the light of the denser calcium vapour, which lies at low levels, or that of the rarer vapour at high levels, the forms of the flocculi corresponding to various superposed regions of the atmosphere can be recorded. The lower and denser vapour appears as bright clouds, but the cooler vapour, at higher levels, absorbs the light from below and thus gives rise to dark clouds.

The first photographs of the sun in hydrogen light were made

with the spectroheliograph at the Yerkes observatory in 1903. These reveal dark hydrogen flocculi, which, like the dark calcium flocculi, lie at a level above that of the bright calcium flocculi. They also show less extensive bright flocculi, usually in the immediate neighbourhood of sunspots, and frequently eruptive in character. These rise from a low level, and sometimes reach considerable elevations in the form of euuptive prominences.

In such an exploration of the sun's atmosphere it might be anticipated that definite currents, or some evidences of atmospheric circulation analogous to those familiar in terrestrial meteorology, would be discovered. In the early work neither the forms nor the motions of the calcium flocculi revealed the existence of such currents, but in the higher region shown by the hydrogen photographs the distribution of the dark flocculi suggested the operation of definite forces, though their full effect was not recognized until the spring of 1908. At that time monochromatic photographs of the sun were first made by Hale and Ellerman on Mt. Wilson with the red (Ha) line of hydrogen, previous hydrogen photographs having been taken with H\$, H\$\gamma\$ or Hδ in the blue or violet. On account of the relatively great strength of Ha at a considerable distance from the photosphere, the new photographs recorded flocculi at high levels previously unexplored. The forms and motions of these flocculi show that great vortices exist in the solar atmosphere above sunspots, which resemble terrestrial cyclones or tornadoes. About 75% of these high-level vortices indicate clockwise rotation in the southern hemisphere and counter-clockwise rotation in the northern, as in the case of terrestrial cyclones. The detection of these vortices led, in 1908, to the discovery of magnetic fields in sunspots, apparently due to electric convection in the primary vortices at lower levels which are the cause of the spots themselves. The long dark flocculi also shown on hydrogen spectroheliograms. identified as prominences projected against the surface of the sun, were subsequently called "filaments" by Deslandres, who has studied them extensively at Meudon. With a spectroheliograph of high dispersion the centre of the hydrogen line Ha shows the "alignments" discovered by Deslandres, which constitute a network of wide mesh associated with the filaments.

Spectrohelioscope.—The spectrohelioscope renders visible to the eye many of the phenomena of the solar atmosphere photographed with the spectroheliograph and also permits their velocities in the line of sight to be measured. It thus combines some of the functions of the spectroheliograph and the velocity spectrograph. Its principle was suggested by Young in 1870, and tried provisionally by him for the observation of prominences at the sun's limb. He discarded it, however, when the use of a wide slit was proposed for this purpose by Zollner and Huggins. Hale, who revived and developed the method (1924), succeeded with its aid in observing the bright and dark hydrogen flocculi on the sun's disk, and in analyzing and measuring the motions of the gas in eruntions and vortices.

Imagine a narrow slit, rapidly oscillating, between the eye and a telescopic image of the sun. Through persistence of vision, the image can be seen in white light. Introduce a spectroscope, which excludes from the slit before the eye all light except that of the red hydrogen line. We then have a spectrohelioscope. For satisfactory observations of the hydrogen atmosphere against the disk. fairly high dispersion is necessary. Hale uses a spectroscope of 13ft. focal length, having a plane grating ruled with about 15,000 lines to the inch, giving a first order spectrum which is very bright in the red. He has employed various means of moving the slits, one of which is a spinning disk pierced with 50 radial slits 0.004in. wide. A 2in. solar image is formed on one side of the disk and the observer sees the hydrogen image of a portion of the sun through a low-power eyepiece focussed on the diametrically opposite slits. J. A. Anderson and Sinclair Smith have suggested devices for producing an exactly similar monochromatic image with a spectroscope having fixed slits. These consist of a rotating prism of square section (Anderson) or an oscillating plane mirror (Smith) which cause a portion of the solar image to move rapidly across the fixed first slit of the spectroscope. The second slit is then viewed through another prism or mirror, moving at precisely the same rate and giving a fixed monochromatic image in the eyepiece.

The hydrogen lines on the sun's disk are frequently distorted by the rapid motion of the gas toward or from the observer. For example, a mass of hydrogen descending into a vortex above a sunspot is indicated by a local displacement of the lines, which frequently indicate a velocity of 60 km. sec. In such a case the distorted portion of the line would fall outside the narrow slit of the spectroheliograph, and the image of the rapidly moving gas would not be recorded. The spectrohelioscope not only brings these moving gases into view but also indicates their velocity. A "line shifter," consisting of a plane parallel-sided glass plate mounted behind the second slit, displaces the line toward red or violet when rotated. In all regions where he suspects motion, the observer frequently shifts the line on the slit, thus "tuningin" so as to pick up the wave lengths as altered by the motion of the luminous gases. In this way, for example, a rapidly ascending mass of hydrogen, near the middle of the sun (revealed by a line outside the  $H\alpha$  line on its violet side), may be watched as it shoots upward, curves over in a long arch nearly parallel for some distance with the surface (its line shown near the centre of the Ha line), and descends in a continuous arch toward the sun or is caught in a vortex and whirled downward (the line being seen outside the  $H\alpha$  line on its red side). A divided arc attached to the line shifter gives the velocity of the gas.

The spectrohelioscope affords a rapid means of detecting and analyzing eruptions or other important solar phenomena, as the entire limb and disk can be examined in a few minutes. Eight or more of these instruments will soon be used systematically at as many solar observatories, distributed around the world, thus permitting the sun's atmosphere to be kept under nearly constant observation. In this way it is hoped to increase our knowledge of the connection between solar cruptions and such geophysical phenomena as the aurora, the magnetic storm and certain interruptions in radio transmission, which probably depend upon the bombardment of the earth's atmosphere by electrified particles projected from the sun.

Descriptions of spectroheliographs and results by G. Hale, H. Deslandres, J. Evershed, Newall and others have appeared in various papers in Astronomy and Astrophysics, Astrophysical Journal, Competes Rendus, Bulletin Astronomical, Monthly Notices of the Royal Astronomical Society and the publications of the Yerkes, Meudon, Kodalkanal, Cambridge and Mt. Wilson observatories, Papers on the spectrohelioscope may be found in the Publications of the National Academy of Sciences, Nature, Astrophysical Journal and Publications of the Astronomical Society of the Pacific. (G. E. H.)

## SPECTROHELIOSCOPE: see Spectroheliograph.

SPECTROSCOPY (from Lat, spectrum, an appearance, and Gr. σκοπεῦν, to see), pertains to the investigation of spectra, the phenomena observed when the radiations from a luminous source are separated into their constituent colours or wave lengths. Such separation results from refraction (as in a prism) or from diffraction (as in a grating). Instruments designed for this purpose are called spectroscopes if used for visual observation, and spectrographs if photography or other methods of recording the spectra are employed. The rainbow, formed by refraction of sunlight in rain droplets, is the most beautiful and common spectrum in nature.

#### HISTORICAL SPECTROSCOPY

The composite nature of white light was first demonstrated by Isaac Newton (1664) when he allowed sunlight entering a round hole in a shutter to pass through a glass prism and fall on a screen. This elongated and coloured image of the sun he called a spectrum. In 1800 W. Herschel studied the spectral distribution of heat from the sun with the aid of thermometers and found the maximum temperature beyond the red end, thus discovering the infra-red spectrum. In 1801 J. W. Ritter, studying the effect of spectral light upon silver salts, found this action extending beyond the violet, thus discovering the ultra-violet spectrum. The first connection between spectral colour and wave length appeared in 1802 when Thomas Young substituted his wave theory of light for Newton's corpuscular theory, explained the

colours of thin films, and calculated the approximate wave lengths of the seven colours recognized by Newton. In 1814 Joseph von Fraunhofer modified Newton's solar-spectrum experiment by substituting a narrow slit for a hole and a telescope for a screen Under these conditions he observed the continuous spectrum of the sun irregularly interrupted by many hundreds of dark lines. still known as "Fraunhofer lines." These lines were the first fiducial marks in spectra, and were promptly exploited as wavelength standards for the comparison of spectral dispersion of various optical glasses. Fraunhofer constructed the first diffraction gratings by winding a fine silver wire upon two fine parallel screws, or by ruling a glass plate with a diamond point, and with these he made surprisingly accurate determinations of wave lengths corresponding to the Fraunhofer lines. Although Fraunhofer and others observed that certain bright lines in the spectra of flames seemed to coincide with dark lines in the solar spectrum it remained for G. R. Kirchhoff in 1859 to enunciate the general law connecting absorption and emission of light and to emphasize the fact that each species of atom has a uniquely characteristic spectrum. Kirchhoff and R. Bunsen (1861), by systematically comparing the solar spectrum with the flame or spark spectra of the purest elements available, made the first chemical analysis of the sun's atmosphere and thus laid the foundation for spectrochemical analysis and for astrophysics (q.v.) In the course of these investigations they discovered spectroscopically two new chemical elements, caesium and rubidium. These demonstrations greatly stimulated spectroscopic research and increased the need for accurate standards of wave length. The first useful standards were provided in 1868 by A. J. Angström who measured the wave lengths of about 1,000 Fraunhofer lines and expressed them in units of 10-10 metre-a unit now known as the angstrom, abbreviated A, and used for all spectroscopic measurements. Further refinements in standard wave lengths were made in 1887 by H. A Rowland who invented and applied the concave diffraction grating In 1892 A. A. Michelson invented the first interferometer. With this instrument he measured the wave lengths of cadmium lines relative to the standard metre and attained an accuracy far exceeding that of any previous work. The wave length of the red radiation from cadmium vapour was remeasured (1905) in terms of the standard metre by R. Benoit, C. Fabry and A. Perot, using the interferometer invented by Fabry and Perot, and since 1907 their value-6,438.4696 A-has been internationally accepted as the primary standard of wave length. Several thousand atomic radiations ranging in wave length between 2,100 and 10,200 A, have been measured relative to this primary standard by interference methods and many of these have been adopted internationally as secondary standards of wave lengths. wave lengths corresponding to lines characteristic of any spectrum whatsoever can be obtained by interpolation between secondary standards impressed on the same spectrogram. In this manner spectroscopists have accumulated wave-length data for several million lines observed in atomic and molecular spectra, extending from the extreme ultra-violet to the far infra-red and embracing nearly 30 octaves as compared with the single visible octave that was first recognized in 1802. These data have served, and will forever continue to serve, in making chemical identifications; since 1885 they have contributed mightily toward the analysis of spectral structures, interpretation of spectra in terms of quantum theory and development of fruitful hypotheses concerning atomic and nuclear structure.

These developments and applications of spectroscopy have unobtrusively but profoundly changed world civilization and have both figuratively and literally expanded the universe (see Light; RADIATION, RAYS).

## EXPERIMENTAL SPECTROSCOPY

Any experiment in spectroscopy involves (1) a source of light; (2) a spectroscope or spectrograph for forming the spectrum; (3) detectors for observing or recording details of the spectrum; (4) measurements of wave lengths and intensities; and (5) the interpretation of such measurements either as chemical identifications or as clues to the structure of atoms and molecules.

#### LIGHT SOURCES

The sun and lightning flashes are examples of bright sources of light occurring in nature. Artificial light sources studied spectroscopically may be divided into two groups according as they emit continuous or discontinuous spectra. A continuous spectrum is characterized by an uninterrupted gamut of wave lengths over a considerable range. Discontinuous spectra exhibit bright lines or bands of different colours or wave lengths on a dark background. Continuous spectra are emitted by incandescent solids and liquids (gas mantle, lamp filament, hot molten metal) or by certain electrical discharges (underwater sparks). These spectra are usually dependent only on temperature and are of no use for identifying the emitting substance; their principal use in experimental spectroscopy is to provide continuous backgrounds for the production of absorption spectra of gases, vapours, solutions, or solids. Discontinuous spectra are emitted by atoms, ions, or molecules in a gaseous or vaporous state in which the individual particles are excited to radiate uniquely characteristic spectra. The particles are excited by absorbing energy either from collisions with other atoms or electrical particles, or from incident radiation. Light sources producing discontinuous spectra are flames, furnaces, and electrical discharges in arcs and sparks at atmospheric pressure, or in lamps containing gases or metal vapours at reduced pressure. In the order named these sources form a rough sequence in which increasing temperatures or energies of excitation are responsible for producing different spectra.

Flames.-Since the days of Kirchhoff and Bunsen it has been customary in elementary chemistry courses to demonstrate spectrochemical identification by dipping a platinum wire into salt solutions, inserting it in a Bunsen burner and examining the spectrum of the coloured flame with a Bunsen spectroscope or Amici prism. Because the temperature of this flame hardly exceeds 2,000° C, the kinetic energy of atomic collisions is not sufficient to produce more than the strongest lines of easily excited atoms like alkalis and alkaline earths. These flames also emit band spectra of carbon compounds and of water vapour present in the gas and air and other bands due to oxides formed in the flame. Higher temperatures, about 2,500° C., are attained in an oxyacetylene flame and atomic spectra are more fully developed. H. Lundegårdh found that when solutions of materials to be investigated were sprayed into such flames 34 elements could be determined spectrographically.

Furnaces.—An evacuated furnace, in the form of a carbon tube heated by forcing large electric currents through it, provides a source of metallic spectra in which the excitation is pure thermal energy. The temperature may be controlled between 1,500° C, where spectra begin to appear, and 3,600° C. where the carbon tube tends to fail. Small samples are placed in a porcelain boat in the tube and the luminous vapour is imaged on the slit of a spectrograph. If a carbon plug is inserted in one end of the tube it provides a continuous spectrum for the observation of absorption spectra of metal vapours. Such furnace spectra have been extensively investigated by A. S. King at the Mt. Wilson laboratory, in Pasadena, Calif., and the results have greatly advanced the understanding of atomic radiation processes, and aided the structural analyses of atomic and molecular spectra.

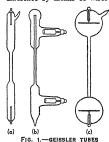

Electric Arcs.—Next to the Bunsen burner the simplest source of atomic spectra is the direct-current arc consisting of an insulated holder for electrodes, an applied potential of 100 or more volts and a resistance to limit the current to 5 or 10 amperes. The actual potential drop in such metallic arcs is 20 to 40 volts, most of which occurs immediately at the cathode. Atomic spectra are very fully developed in electric arcs because the temperatures range from 3,500° to 8,000° and all known substances are melted and vaporized. In addition to violent thermal agitation, many atoms collide, especially near the electrodes, with electrons or ions accelerated by the applied potential. For the study of metallic-arc spectra it is best to use solid rods of the pure metals themselves; other forms of material (powders, salts, precipitates, ashes, filings, foils, refractories, minerals, etc.) are readily volatilized by placing some of the substance on the lower (positive) pole of a pure carbon arc. The direct-current arc is characterized

by high intensity and effectiveness in generating the first spectra of atoms, but it is subject to erratic wandering and flickering which impair its usefulness for accurate spectrochemical analysis unless standardized conditions are imposed. A high voltage (2,200 volts) alternating-current arc, introduced in 1936 for quantitative analysis, reduces some of the irregularities of the direct-current arc at the expense of simplicity and sensitivity of spectral detection.

Electric Sparks .-- Compared with the electric arc the highvoltage condensed spark supplies higher excitation and is easier to control. Initially the high voltage was produced by a Rhumkorff induction coil, and a Leyden jar served as a condenser. In its modern forms the spark is animated by discharges from suitable condensers connected, in parallel with the spark gap, to the secondary terminals of a transformer giving from 10,000 to 50,000 volts. The condenser is charged on every half cycle to the voltage at which the gap breaks down. An oscillating current then flows in the spark circuit with an initial value of  $I = V\sqrt{C/L}$ where V is the condenser voltage, C the capacity in farads and L the circuit inductance in henrys. This initial current may be hundreds of amperes and the result is an energetic emission of excited or ionized atoms from the electrodes. Such sparks have higher effective temperatures than arcs. Indeed, in the highest attainable vacuum these sparks produce multiple ionization until atoms are stripped of all outer electrons and the corresponding temperature is estimated at several million degrees. The ordinary spark is somewhat variable owing to lack of constancy in breakdown potential or in the rate of decay of the oscillating discharges in each half cycle. Several devices have been introduced to control or stabilize sparks used for quantitative spectral analysis. Such devices are the synchronous auxiliary rotating spark gap and the air-blasted auxiliary gap. Any conducting solids may be used directly as spark or arc electrodes.

Other substances will serve as electrodes if they are packed in a hollow carbon rod or if they are pressed into solid form with some binder such as pure copper powder, but in such cases the spectrum of the substance is contaminated by that of the auxiliary electrode material.

Geissler Tubes.—An important type of light source is that produced by electrical discharges in gases at reduced pressures, first demonstrated and studied by J. Plücker in 1858 (fig. 1). It usually consists of a small-bore or capillary tube of glass (or silica) connecting two bulbs or larger bore tubes containing metal electrodes which can be attached to an electrical potential difference by means of wires leading through the glass. These

(a) original Geisster, (b) modern Geissier, (c) NBS Geisster

light sources are prepared by thoroughly exhausting the lamp, then admitting some pure gas (or vapour) through a side tube and sealing it off with a blowtorch when suitable conditions are established. The optimum pressure of gas is usually that equivalent to a few millimetres to a centimetre of mercury. When electrical potential is applied to such tubes a sheath of ions near the cathode marks the edge of the cathode fall within which electrons released from the cathode by ion bombardment attain sufficient speed to produce new ions by collisions with gas atoms. Outside this negative

glow is the Faraday dark space, and beyond it is the positive column extending nearly to the positive electrode. This positive column is responsible for most of the light emission, and being a region of relatively low potential gradient and electron speeds, it favours the first spectrum of the included gas. A glass blower named Heinrich Geissler, under Plücker's direction, prepared the first gaseous discharge tubes, and Plücker himself referred to them as "Geissler tubes"—a name that still clings to them. About 1930 a modified form of the Geissler tube became a spectacular type of light source for luminous coloured signs and shortly thereafter helium, neon and mercury lamps became commonplace. A more recent modification of the Geissler tube is the fluorescent lamp consisting essentially of a low-pressure mercury vapour tube whose discontinuous spectrum is partially converted to continuous bands characteristic of the fluorescent materials lining the inner walls of the tubes.

Hollow-cathode Discharge.—Another type of gas discharge of great utility for spectroscopic research is that devised by F Paschen. It consists of a hollow cylindrical cathode within a cylindrical anode, and a low pressure of pure noble gas. As the pressure is reduced the discharge retreats within the cathode until, at a pressure such that the mean free path of the electrons equals the cathode diameter, the negative glow fills the hollow cathode. The material of the cathode, or of any other metal within it, is vaporized by bombardment of the noble gas ions and excited by collisions with electrons whose maximum speeds are fixed by the ionizing potential of the sustaining gas. Since this source is operable at low pressures and low temperatures (the cathode may be cooled with liquid air) it yields atomic spectrum lines of extraordinary sharpness.

Electrodeless Discharges .- Gases or metal vapours may also be made luminous at low pressures in closed vessels without internal electrodes by placing the vessel inside a coil carrying a high frequency current generated by either a Tesla spark generator or a vacuum tube oscillator of ultra-high radio frequency. The oscillating high-frequency electric fields accelerate electrons sufficiently in rarefied gases and metal vapours to excite atomic and ionic spectra. These electrodeless discharges are especially convenient for minute quantities of pure materials (such as artificial elements), or for gases and vapours which attack electrodes or which may be contaminated by them.

Linelike Sources.-When viewed through a spectroscope any of the above mentioned light sources will be seen as a multitude of images, one for each monochromatic radiation characteristic of the excited atoms or ions in the source. Since all practical light sources are more or less wide these spectral images will overlap even if the spectroscope has enormous resolving power. In the case of electrical discharges in gases and metal vapours at reduced pressure, the light source is usually constructed with a long constriction to increase the intensity and this incidentally reduces the confusion of overlapping spectral images. However, in general, it is not possible to make all light sources linelike except by imaging the light source on a narrow slit with straight parallel jaws in which case the illuminated slit becomes the light source and the spectrum is a series of bright line images of the slit. The same effect may be obtained by substituting for the slit a cylinder of polished metal about one millimetre in diameter, and using the virtual image of any light source in this cylindrical mirror as a linelike light source. It is emphasized that spectral "lines" do not occur in nature but are consequences of using an artificial linear light source, because it gives the least confusion of overlapping images.

## SPECTROSCOPES AND SPECTROGRAPHS

Prism Instruments.-The production of a spectrum by the use of a prism of glass or any transparent material depends upon the fact that light rays of different colours, or wave lengths, are refracted differently on passing obliquely from one medium to another of different density. A composite ray of light is accordingly dispersed as well as refracted in passing through a prism, the amount of refraction being usually greater for shorter wave lengths. The first prism spectroscopes employed by Newton and by Fraunhofer exhibited astigmatism, a type of image defect in which a point source is seen as two perpendicular image lines at different distances from the optical system. This defect was effectively eliminated in Kirchhoff and Bunsen's first spectroscope by using a collimating lens to illuminate the prism with parallel rays. Astigmatism is least and definition best in a prism spectroscope if the prism is traversed by parallel light, the slit is parallel to the prism edge, the light rays are parallel to a section perpendicular to the edge, and the rays pass through the prism symmetrically at minimum deviation. The essential parts of a simple prism spectroscope are sketched in fig. 2. Light from a source under examination enters the spectroscope through a narrow slit S located at the principal focus of the collimator lens C. Parallel rays of complex light thus fall on the prism, and rays of each component colour continue parallel in their passage through the prism and on emerging from it. The colours are refracted differently, and after passing through the telescope lens T are focused to form a spectrum which may be observed with an eyepiece or recorded on a photographic film.

The brightness of the spectrum depends upon the wav in which the slit is illuminated by the light source, upon the focal lengths and apertures of the spectrograph lenses, and upon reflection and transmission losses within the instrument. The maximum illumination is attained if the light source is large enough or so close

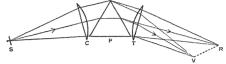

FIG. 2 .- PRISM SPECTROSCOPE OR SPECTROGRAPH Saslit, Cacollimator lens, Pa60° prism, Tatelescope lens, RVared to violet spectrum

to the slit that it subtends the same angle as the collimator lens. If the source is too small to fill the collimator with light the brightness of the spectrum may be increased by using a condensing lens of equal aperture ratio to form an image of the source on the slit. This type of slit illumination of a stigmatic spectrograph gives a point to point correspondence between a section of the source, the slit and the spectral images; it is preferred when the distribution of excitation in a source or of energy in an interference pattern is to be studied. When a perfectly uniform slit illumination is desired, as for the measurement of spectral-line intensity ratios by means of stepped filters, a condensing lens is placed just in front of the slit to form an image of the source on the collimator lens, in which case each point of the source sends light to every point of the slit and to every point of the spectral image. In either case a movable metal slide pierced with a series of openings (known as a Hartmann diaphragm) may be used to illuminate successive portions of a slit and thus record on a stationary photographic plate a number of spectra side by side for comparison and for measurement.

The light efficiency of a spectrograph, like that of a camera or telescope, depends chiefly on the ratio of the focal length, F, to the diameter, D, of the lenses, F/D. This ratio may be 100/1 or more in spectrographs employed for the study of bright sources like the sun, but extremely faint sources like phosphorescence or the night sky demand unit ratio or less. A ratio of about 15/1 represents a common compromise between desired speed and the necessity of using compound corrected lenses. In such spectrographs single plano-convex or meniscus collimator and camera lenses may be used if the curvatures are chosen so as to minimize spherical aberration and coma, and the plate is tilted and bent to fit the chromatic focus. The inclined plate obviously provides an increased spectral dispersion, and the use of single lenses ensures that light losses resulting from absorption and surface reflections are a minimum.

When all relevant factors are considered it appears that an isosceles prism with 60° angles is the best form for a spectro-graph. As to prism and lens materials there is a wide choice of optical glasses for the study of visible and near infra-red spectra but for spectral regions absorbed by glass it is necessary to use other materials such as crystalline quartz or fluorite in the ultraviolet, and rock salt or other alkali halides in the infra-red. Unfortunately, no crystals, natural or artificial, are transparent to all wave lengths; quartz is opaque below 1,800 A, and fluorite below 1,200 A, whereas rock salt is opaque above 17,000 A, and potassium iodide above 31,000 A. Furthermore they have limitations on account of size, homogeneity and cost. For ultra-violet spectrographs the most popular material is crystalline quartz But quartz polarizes the light it transmits and produces double images both on account of its birefringence and its property of rotating the plane of polarization. The birefringent effect is eliminated by cutting quartz lenses and prisms so that the light travels along the optical axis of the crystal, and the rotation doubling can be compensated by using equal parts of natural left-handed and right-handed quartz. A simple quartz spectrograph, therefore, has a collimator lens of one variety of quartz, a camera lens of the other variety, and the 60° prism is made by combining two 30° prisms of the opposite varieties of quartz. The same effect is obtained with economy of material in a Littrow-type spectrograph consisting of a single quartz lens and a 30° quartz prism backed by a mirror. (See fig. 3.) Obviously the rotation doubling

FIG. 3.-LITTROW QUARTZ SPECTROGRAPH

experienced by light in its forward passage through the lens and prism is cancelled by its return along the same path after reflection from the mirror or metallic coating on the back of the prism.

Received it this packability and possibly for visual bears,

Because of their portability and popularity for visual observations of spectra two types of compound prisms, the Amici and the Pellin-Broca, deserve brief descriptions. A form of "directvision spectroscope," invented in 1860 by G. B. Amici, consists of two prisms, ABC and CDE (fig. 4) of crown glass, having a low ratio of dispersion to index of refraction, cemented to a prism BCD of flint glass having a high ratio of dispersion to

FIG. 4.—A MICI DIRECT-VISION SPECTROSCOPE
ABC=CDE=crown glass, BCD=fint glass, PV=red to violet spectrum

index. The prism angles are so chosen that the median spectral ray is undeviated upon emergence but all other rays are refracted and dispersed. Greater dispersion and resolving power are obtained by assembling trains of five or seven prisms.

five or seven prisms.

A type of "constant-deviation spectroscope," invented in 1899

by P. Pellin and A. Broca, has a four-sided prism ABCD (fig. 5) which is effectively a combination of two 30° refracting prisms ABE and DAC, and a totally reflecting right-angle prism BEC. Since the two refractions cancel and a right-angle deviation is introduced by the internal reflection the collimator and telescope axes are fixed 90° apart and different wave lengths are brought into the field of view by rotating the prism with a screw to which

a wave length calibrated drum is attached.

Dispersing Power of Prisms. —The power of any spectroscope to separate different wave lengths emerging at different angles and focused at different points is called its dispersion; it is defined as the rate of change of the angle of deviation,  $\theta$ , with respect to a small change in wave length,  $\lambda$ , and represented mathematically by  $d\theta/d\lambda$ . Since  $\theta$  varies with the refractive index, n, of the prism, and the refractive index varies with the wave length,  $\lambda$ , we may write

Angular dispersion = 
$$\frac{d\theta}{d\lambda} = \frac{d\theta}{dn} \cdot \frac{dn}{d\lambda}$$
.

Dispersion thus depends upon two factors. The second factor,

 $dn/d\lambda$ , is determined solely by the optical properties of the prism material. Since the refractive indexes of a glass prism are approximately represented by an equation of the (Cauchy) form  $n=a+b/\lambda^2$ , where a and b are constants obtained from measured values of n for two different wave lengths,  $dn/d\lambda = -2b/\lambda^3$ . The negative sign merely indicates increase of n with decrease of  $\lambda$ . This formula shows that the dispersive power of a glass prism varies inversely as the cube of the wave length. For example, the dispersion at 4,000 A is about eight times that at 8,000 A. The other factor,  $d\theta/dn$ , depends upon the angle of the prism, and on the angle it presents to the incident light. If, as in fig. 6a, the angle of incidence and emergence be represented by i, and i<sub>n</sub> respectively, the internal angles of refraction by n, and n the angle of the prism by n, and the angle of deviation by n, it is readily deduced from Snell's law of refraction,  $n = \sin i / \sin n$ , that

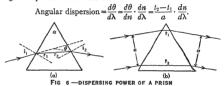

$$\frac{di_2}{dn} = \frac{\sin (r_1 + r_2)}{\cos r_1 \cos i_2}$$

or, since  $d\theta = di_2$ , and  $r_1 + r_2 = \alpha$   $\frac{d\theta}{dn} = \frac{\sin \alpha}{\cos r_1 \cos i_2}$ 

This expression clearly shows the dependence of the dispersion upon the prism angle and the angle of incidence. A convenient equivalent expression was first deduced by Lord Rayleigh; namely,

 $\frac{d\theta}{dn} = \frac{t_2 - t_1}{a}$ 

where  $t_2$  and  $t_1$ , in fig. 6b, are the lengths in the prism traversed by the extreme rays, and a is the breadth of the emergent beam. When the prism is at minimum deviation and completely covered by the beam,  $t_2-t_1$  is simply the base length of the prism. The original expression now becomes

When there is more than one prism  $t_2-t_1$  is summed for all prisms, and in Amici prisms the algebraic sum is taken, the lower dispersions being regarded as negative. The angular dispersion may be expressed in radians or degrees per angstrom, but it is usually more convenient to measure linear dustances, x, in the focal plane and express linear dispersion  $dx/d\lambda$  in millimetres per angstrom. In general, if f is the focal length of the image forming lens,  $dx/d\lambda = f/d\theta/d\lambda$ .

Resolving Power of Prisms .-- It would appear from this equation that, by choosing a large focal length, it would be possible to separate two close slit images due to light of two wave lengths, however little the wave lengths differed. Such, indeed, would be the case if an infinitely narrow slit were imaged as an infinitely narrow line. However, owing to the wave nature of light any optical image is a diffraction pattern of finite size which depends both on the wave length and on the dimensions of the optical system. An instrument is thus limited in its power to resolve images of slightly different wave length, or closely adjacent spectrum lines. This resolving power, R, is expressed numerically as the ratio of a mean wave length \( \lambda \) to the least difference  $d\lambda$  between two wave lengths that can be recognized as a double image, i.e.,  $R = \lambda/d\lambda$ . Each actual image of the slit is a diffraction pattern having most of the light concentrated in a central band of finite width flanked by secondary bands of negligible intensity. If f be the focal length of the camera lens, and a the effective breadth of the beam passing through a rectangular cross section, the half width, w, of the central diffraction band is given by the elementary theory of diffraction as  $w = f\lambda/a$ . This says that the image width increases with focal length and with wave length. but decreases with aperture increase. The condition for resolution is explained in fig. 7 where the spectrum is focused on a screen by a lens of focal length f. The beams of two equal-amplitude closely-adjacent wave lengths  $\lambda$  and  $\lambda+d\lambda$  are separated by the prism an increment of angle  $d\theta$ . Each slit image appears as a diffraction band, and, according to Rayleigh's criterion, resolution is just effected when the central maximum of one image coincides with the first minimum of the other, i.e., when the distance between centres of the two bands is w. Under these conditions the integration of the two bands gives a curve with two maxima, and if the intensity of these be rated as unity that of the minimum between is 0.81. Experience has shown that this intensity difference is sufficient to reveal duplicity of the image

and the condition for resolution is thus  $d\theta = w/f = \lambda/a$ ; or  $\lambda = a \cdot d\theta$ . By definition,  $R = \lambda/d\lambda$ , and therefore  $R = a \cdot d\theta/d\lambda$ , or in Rayleigh's form.

 $R = (t_2 - t_1) \cdot dn/d\lambda$ .

When there are several prisms, the algebraic sum is to be taken as in the case of dispersion. An ordinary flint glass prism of one centimetre base is found to have a resolving power for sodium-yellow light of about 1,000 but this number increases rapidly with decreasing wave length since  $ds/dh = -2b/\lambda^3$  approximately.

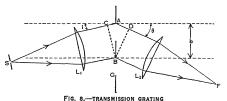

An infinitely narrow slit was assumed in the derivation of the theoretical resolving power but such a slit would transmit no appreciable light. In practice it is necessary to use a slit of finite width and sacrifice some of the resolving power for the sake of intensity in the spectral images. The actual separating power with finite slits was called "purity" by A. Schuster who defined a "normal slit" as the product of a quarter wave length by the aperture ratio,  $\frac{\lambda \cdot F}{4 \cdot D}$ , and calculated that nearly 99% of the

theoretical resolving power was conserved by using this normal slit. Thus, if F/D=20 the normal slit for 4,000 A would have a width of \$ Ao  $*_2$ . If double the normal slit is used the resolving power is reduced to 94% of maximum but the intensity is doubled. Increasing the slit width to about four times normal reduces the resolving power to 80% but trebles the intensity. Still wider slits rapidly reduce the resolving power or spectral purity without appreciably intensifying the spectra of monochromatic images except where they overlap. A wide slit greatly increases the intensity of continuous background relative to that of monochromatic lines. The above definitions of dispersing power, resolving power and spectral purity are valid also for diffraction gratings discussed below.

Grating Spectrographs.-The use of diffraction gratings instead of refraction prisms for the study of spectra brings advantages of constant and usually greater dispersion and resolution, as well as opportunity to observe extreme ultra-violet and infra-red spectra for which no transparent prisms can be found. Modern gratings are made by ruling with a diamond point equidistant parallel lines on a polished plate of glass, of speculum (copper+tin) metal, or of glass on which a film of aluminum has been deposited. Those in most general use for visible and ultra-violet spectra have either 15,000, 20,000, 24,000, or 30,000 lines per inch and effective ruled areas ranging from about 2 to 6 inches. A grating with 15,000 lines per inch permits measurements in infra-red spectra to 30,000 A, but for the investigation of longer waves coarser gratings must be used. In 1910 R. W. Wood first ruled 2,000 to 3,600 lines per inch on copper plates and by proper choice of groove form succeeded in concentrating much of the visible light into relatively high orders. Such "echellete" gratings concentrate the greater part of infra-red energy in a first-order spectrum and they

can be ruled to perform in this manner for almost any desired wave length. Thus, a grating with 900 lines per inch may be made to function well at about 300,000 A, 360 lines per inch around 900,000 Å and 80 lines per inch around 1,500,000 Å. These coarse echellete gratings have ruled surfaces up to 10x20 inches in area and are usually cut in a solder surface with a steel tool. A grating ruled on a sheet of transparent glass is called a "transmission grating," but it is impossible to rule large areas of glass without wearing down the diamond point. For shis and other good reasons most gratings are ruled on opaque soft metal surfaces, and are called "reflection gratings." The fundamental principle is the same in both cases.

The cory of Diffraction Gratings.—The simple theory of the plane diffraction grating gives the wave length of light as a function of the grating space and of the angles of incidence and diffraction of the light rays. Fig. 8 represents the cross section of a transmission grating in which transparent and opaque lines o spaces alternate and each pair, such as  $AB_i$  is called the grating space b. If light from an illuminated slit S falls as a parallel beam on the grating at an angle of incidence i with the normal, a portion of the light passes directly through the grating aperture to produce an undeviated image, but a part of it is diffracted in the direction AD making an angle  $\theta$  with the normal. After drawing the perpendiculars CB and DB it is seen that the difference in

S-slit, L<sub>1</sub>=collimator lens, G=Grating, L<sub>2</sub>=camera lens, b=grating space, i=angle

path travelled by corresponding rays from adjacent apertures, or the retardation as it is called, is given by the sum of the lengths CA and AD. When this retardation is equal to any integral number, u, of wave lengths,  $\lambda$ , bright images of S in colour corresponding to  $\lambda$  are produced where the diffracted rays are brought to a focus, F. This condition is simply expressed by the equation

$$CA + AD = n\lambda = b$$
 (sin  $i + \sin \theta_n$ )

in which n represents the order number of the spectrum.

of incidence, θ=angle of diffraction, F=focused spectrum

The law of reflection gratings is similar to that of transmission gratings. Thus in fig. 9 a beam of parallel rays falls on a plane reflection grating with grating space AB=b. The incident light makes an angle, i, with the normal, and part of the light is diffracted at an angle,  $\theta$ . The perpendiculars AC and BD show that BC and AD are the retardations. In this case the total retardation is AD-BC=b (sin i—sin  $\theta_n$ ). Whenever this equals one or  $\theta_n$  are the retardation where  $\theta_n$  is  $\theta_n$  and  $\theta_n$  are the retardation  $\theta_n$ .

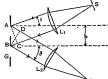

FIG. 9.—REFLECTION GRATING

L<sub>ω</sub>=camera lens, b=grating space, is
angle of incidence, θ=angle of diffraction, F=focused spectrum

bright image is seen in colour corresponding to  $\lambda$  and we have the law of the grating. If the diffracted rays are on the same side of the normal as the incident rays the two retardations are added, wherefore the general equation for all spectra must be written  $n\lambda = b$  (sin  $i\pm\sin\theta_n$ ), the positive or negative sign being used when the incident and diffracted rays are on the same or opposite sides of the normal,

respectively. If the grating space is not too small the groove form of the ruled lines can be controlled by shaping the diamond point in such a way that the diffracted light is largely concentrated in one general direction or spectral region. Such gratings may for example, give an intense visible spectrum and weak ultra-violet, or vice versa. If light is incident normally on any grating the angle i is zero and the grating formula reduces to  $\pm n\lambda = b \sin \theta$  which represents a central zero-order image flanked on either side by first, second, third, etc., order spectra according as  $n=\pm t, \pm 2, \pm 3$ , etc. It is obvious that the absolute values of wave lengths may be determined from the measurement of the grating space and of one (or two) angles. This was the method employed by Fraunhofer, and by Ångström to establish standards or fiducial points in spectra.

Concave Gratings .- All plane gratings, like prisms, require the use of lenses or mirrors to collimate and to focus the incident and emergent light. To eliminate lens aberrations and limitations of light absorption, Rowland in 1881 first ruled a grating on a spherical mirror which collected light from a slit, dispersed the diffracted light into spectra and focused them on a circle the diameter of which equalled the radius of curvature of the concave grating. All concave gratings mounted on the Rowlandcircle principle exhibit strong astigmatism, i.e., a point slit is imaged as a line with a length dependent on wave length and spectral order. This astigmatism reduces the brightness of the spectra and precludes the use of diaphragms or sectors at the slit, and other observations requiring a one to one correspondence in the slit and its spectral images. Fortunately this defect can be avoided either by placing horizontal lines to be focused on the circle at a greater distance from the grating than the slit, or by illuminating the concave grating with parallel light, in which case the astigmatism is practically eliminated and the brightness of spectra greatly increased.

With both plane and concave gratings a great advantage is obtained by forming and observing spectra on the normal to the reflecting surface, for this gives the "normal spectrum" in which angular or linear distances measured either way from the grating normal are, for a considerable distance, proportional to the change in wave length observed. Since the concave reflection grating is free from chromatic aberration and focuses all spectra on the same focal surface, Rowland took advantage of the normality of spectra and of the coincidence principle in overlapping orders of spectra to determine the relative values of the "Rowland system" of standard wave lengths.

**Dispersion.**—The explanation of dispersion by a grating is easily seen since the formula shows that the angle  $\theta$  increases or decreases with the wave length  $\lambda$ . When composite light falls on the grating it is obvious that the shorter violet waves will give an image closer to the central image than the longer red waves, and successive orders of spectra will increase in dispersion proportional to the order number.

If  $\theta$  be the angle of diffraction, dispersion is defined as before by  $d\theta/d\lambda$ , and since, for a given position of the grating, the angle of incidence, i, is constant, the grating formula gives  $d\theta/d\lambda = n/b \cos \theta$ . This equation shows clearly how the dispersion varies directly with the order of the spectrum, and inversely as the grating space; the closer the rulings the greater the dispersion, irrespective of the total number of grating spaces. Furthermore the dispersion is smallest when  $\cos \theta$  has its maximum value (which is unity for zero angle), i.e., when the spectrum is observed normal to the plane of the grating. In this position also the dispersion is most nearly uniform throughout the spectrum, since it varies with  $\cos \theta$ , and in the proximity of  $\theta = 0$ this trigonometric function changes very slowly. The spectrum given by a grating, unlike that given by a prism, is accordingly 'normal" in so far as  $\cos \theta$  can be considered constant. There is a certain amount of overlapping of successive orders since  $n\lambda$ may acquire the same value in different ways. For example,  $\lambda =$ 7.000 A in the first order will be coincident with  $\lambda = 3,500$  A in the second order, and  $\lambda = 4,000$  A in the third order will coincide with  $\lambda = 6,000$  A in the second. When observation of a particular spectrum is desired it is usually possible to remove the overlapping spectra by using suitable colour filters in front of the slit or selective detectors at the focus.

Resolving Power.-As in the case of the prism, the resolving

power of a grating is a theoretical quantity expressing the imageseparating power when the slit is indefinitely narrow; it is represented symbolically by  $R = \lambda/d\lambda$ , and is given in simple form by R = nN, where n is the order number of the spectrum and N is the total number of rulings. Thus the resolving power of a grating depends only on the total retardation in wave lengths from the first to the last line, and not on the grating space. For example, a five-inch grating with 20,000 lines per inch would have a theoretical resolving power of 200,000 in the second order, surpassing an imaginary glass prism of two metres base length At  $\lambda = 8,000$  A,  $d\lambda$  would be 0.04 A, while at  $\lambda = 4,000$  A it would be 0.02 A. This theoretical resolving power is attained only under ideal conditions since actual resolution depends on various factors such as the relative intensities of spectral lines, their form or structure, the width and manner of illuminating the slit, the perfection and adjustment of the optical parts, graininess or contrast of photographic emulsions, etc.

Interferometers.—Since the resolving power of a grating is proportional to the product (nN) of the order number and the total number of elements, it may be increased in two ways. To increase the number of elements the number of lines per inch may be increased or a greater number of inches ruled, but the total number of useful lines is usually limited to about 100,000 by the practical difficulties of making all grooves exactly alike and equally spaced. The alternative method of using higher orders is limited in highly dispersive gratings by the great reduction in aperture when the grating is viewed tangentially. These limitations in ruled gratings are circumvented more or less in certain interferometers, known as Michelson's echelon interferometer, the Fabry-Perot interferometer and the Lummer-Gehrcke interferometer, all of which employ a relatively small number of elements (10 to 30) but very large spectral orders (10,000 to 100,000 or more). Since such high orders are very close together confusion due to overlapping of many lines must be avoided by crossing these interferometers with any stigmatic spectrograph. The Michelson transmission echelon (fig. 10) consists of a number of glass plates of equal thickness, t (c. 1 cm.), and refractive index,  $\mu$ , but each shorter than its predecessor. These are wrung into optical contact with each other to form a series of steps, i.e., an echelon. Parallel light from a collimator, with the slit parallel to the edges of the steps, is then passed through the larger end.

Saslit, Lacollimator lens, lainterferometer, Lachromatic lens, Eacycpiece

In each step the light is retarded an equal amount  $(\mu-r)t/\lambda$  and diffraction spectra of very high order are formed when all the transmitted beams are collected and focused by a lens. This interferometer was later improved as a reflection echelon which is not limited by the absorption of glass and has nearly four times the resolving power since the retardation per step is  $2t/\lambda$ . An echelon of 30 plates each 1 cm. thick has a theoretical resolving power at 5,000 A of 30×2/.0005=1,200,000. This instrument has been employed for the examination of spectral line structure and for the precise measurement of relative wave lengths.

When a beam of light passes through a transparent film or plate multiple reflections occurring at the surfaces produce interference colour effects seen for example in soap bubbles or in oil films on a wet pavement. Such interference bands are relatively broad because the reflecting power is so low that only the first reflection at each surface is effective. When the reflecting surfaces are exactly parallel and the reflection coefficient is increased, the multiple reflections produce very narrow bright fringes on a broad dark background. These conditions are met in the Fabry-Perot and in the Lummer-Gehrcke interferometer. In the former a large coefficient of reflection is obtained by depositing bright partly-transparent metal films on two glass or quartz planes. These planes are mounted face to face, separated some milli-

metres or centimetres, and adjusted to exact parallelism. The most common type of Fabry-Perot interferometer (fig II) is the fixedetalon type in which the plates are maintained at a fixed distance by being pressed against a separating ring spacer or etalon. When illuminated with monochromatic light, and viewed axially, circular interference bands, known as Haidinger's fringes, are seen at infinity. When illuminated with complex light the overlapping of fringes belonging to neighbouring spectral lines is avoided by crossing the interferometer with a stigmatic spectrograph. The order of interference at the centre of the pattern for wave length  $\lambda$  is in general a whole number, n, plus a fraction,  $\epsilon$ , determinable from the diameters of successive rings. The double distance between the interferometer plates is  $2D=\lambda (n+\epsilon)$  for wave length  $\lambda$ , or  $2D = \lambda'(n' + \epsilon')$  for another wave length,  $\lambda'$ . Thus the simple proportion  $\lambda/\lambda' = (n' + \epsilon')/(n + \epsilon)$  offers an opportunity for the precise comparison of wave lengths, and this is in fact

FIG. 11 ——FABRY-PEROT INTERFEROMETER

the method employed for the establishment of secondary standards of wave length measured relative to the primary standard (red radiation from cadmium) which was itself found to be 6,438.4696 A by comparison with the meter. (See Interferom-ETER.) This method of comparing wave lengths has been used extensively also for measuring the ratios of wave lengths in vacuo and in gases and thus determining the refractive indexes and dispersions of gases, notably air. In addition the Fabry-Perot etalon interferometer has proved the most effective instrument for the measurement of exceedingly small wave length differences which appear, for example, in hyperfine structure, isotope shifts, pressure shifts, etc. Besides simplicity, stability and freedom from defects this interferometer possesses a large advantage in the flexibility of its resolving power, since this is equal to the product of the spectral order, n, by the effective number of reflections, N. With a reflection coefficient of 0.75 the value of N is about 10, and with 0.90 the effective number of reflections is about 30. Thus a Fabry-Perot interferometer with silver mirrors reflecting 0.90 is equivalent to a reflection echelon of 30 plates having plate thickness equal to the etalon separator. The echelon plates have a fixed thickness whereas the Fabry-Perot plates may be separated as desired to increase resolving power.

In fact, the highest resolving powers on record have been attained with Fabry-Perot interferometers and the most detailed and reliable results on hyperfine structure must be credited to them.

The Lummer-Gehrcke interferometer consists of a long unsilvered plate with perfectly plane parallel surfaces in which a high reflection coefficient is obtained by directing the entering light beams so that they are reflected at nearly the critical angle (fig. 12). The greater part of the light is reflected at each internal reflection but the remaining fractions emerge with equal retardations as parallel refracted beams which may be collected and focused by a lens to form identical sets of interference patterns above and below the optic axis. The resolving power is

rig, 12.-LUMMER-GEHRCKE INTERFEROMETER

again n N where n is the order of interference (retardation) and N the effective number of reflections or emergent beams, which usually ranges from 10 to 20. The practical resolving power of

the Lummer-Gehrcke interferometer has been found to be about equal to the length of the plate measured in wave lengths. This instrument has been employed successfully for the observation of hyperfine structure, isotope shifts and Zeeman patterns.

The most famous of all interferometers is the very first one, invented by A. A. Michelson in 1892, and fully exploited by him in his classical investigations of "ether drift," sharpness of spectral lines, and evaluation of the international metre in wave lengths of cadmium radiations (see INTERFEROMETER).

#### METHODS OF OBSERVING OR RECORDING SPECTRA

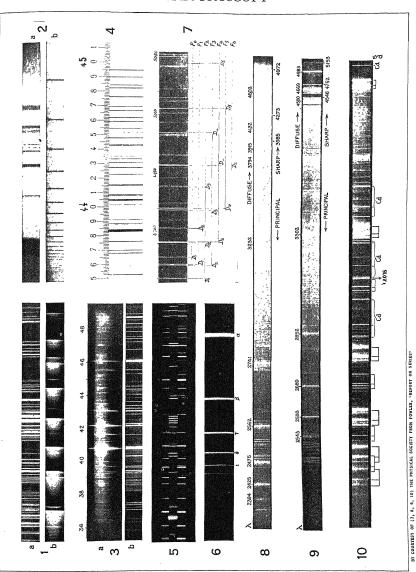

There are in general four ways of observing spectra: visually, photoelectrically, radiometrically, and photographically; each having certain advantages and limitations.

Visual.—Although the average human eye is extraordinarily sensitive for green light  $(5,500 \, \text{A})$ , its sensitivity declines rapidly to zero for infra-red ( $\lambda \geq 7,700 \, \text{A}$ ) and ultra-violet  $(\lambda < 3,800 \, \text{A})$ . Being highly selective, variable, localized and restricted to one octave, visual methods of observing are relatively unimportant in spectroscopy.

Photoelectric .-- As a substitute for the human eye the "electric eye" or photoelectric tube may be employed for the investigation of spectra in limited ranges. Briefly, the photoelectric tube consists of two metal electrodes in an evacuated glass tube. The anode is maintained at a positive potential with respect to the cathode. When radiation falls on the cathode the liberated electrons are drawn across the evacuated space to the anode. This flow of electrons constitutes a photoelectric current which is directly proportional to the incident energy. Since these photoelectric currents are usually very small they are magnified by the use of thermionic amplifiers, or in the case of feeble radiation, use is made of a Geiger-Müller tube in which each electron emitted gives rise to a pulse of current. Since 1940 multiplier phototubes, in which enormous amplification is obtained by a sort of chain reaction, have become popular as detectors and intensity recorders of spectral lines. All photoelectron emitters (e.g., Na, Zn, Cd, Mg) are highly selective and usually most efficient in the ultra-violet. By depositing thin films of heavy metals or compounds (e.g., CsO, PbS) photoelectric sensitivity may be extended to near infra-red, but not much beyond 40,000 A.

Radiometric .-- A unique and important class of radiation detectors, responding to the heating effect of the radiation, is found in blackened radiometers, radiomicrometers, thermopiles and bolometers. They are unique because they are nonselective, and important because their sensitivity extends from ultra-violet, through visible, to far infra-red spectra. The radiometer is a blackened vane supported some distance from the axis of rotation of a glass or quartz fibre in vacuo. When radiation is absorbed by the vane the supporting fibre is twisted through an angle proportional to the incident radiation. The radiomicrometer is essentially a moving coil galvanometer of the D'Arsonval type. A single thermocouple is suspended by a quartz fibre with the plane of the couple coil in the line joining the poles of a magnet. When radiation falls on the thermocouple junction the electric current generated causes the couple to turn in the magnetic field. The thermopile consists of one or more junctions of dissimilar metals, e.g., bismuth and antimony or silver, iron and constantan (alloy of nickel and copper). If radiation falls on alternate junctions a galvanometer in the circuit will give a deflection proportional to the heating effects. All radiation detecting and measuring devices depending upon the initial conversion of radiant energy into heat energy and finally into mechanical or electrical energy are extremely inefficient because all heat engines are naturally inefficient. The feeble final effects of radiation may be magnified up to about 200 times by suitable amplifiers but thermopile currents causing galvanometer deflections of the same magnitude as Brownian-motion effects obviously cannot be amplified to advantage.

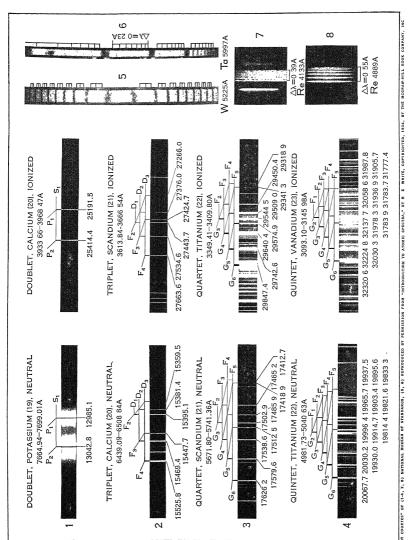

The bolometer, devised by S. P. Langley in 1880, consists of two similar very thin strips of metal, usually platinum, which form two arms of a Wheatstone bridge. The strips are blackened

on one side, one strip is shielded and the other is exposed to radiation. The absorption of radiation by one strip increases its temperature, thus changing its electrical resistivity and causing a deflection of the galvanometer. With his bolometer Langley, in 1888, mapped the solar spectrum to 55,000 A by using a spectrometer with rock salt lenses and prisms and passing the spectrum over the bolometer strip by rotating the prism. The galvanometer readings were recorded on photographic paper whose motion was co-ordinated with that of the prism. The same basic principles are today employed, with improved instrumentation, in all automatic recording of spectra scanned either by photoelectric or radiometric detectors.

Photographic.-The actinic action of radiation on silver salts is fairly effective throughout many octaves of spectra, from blue to extreme ultra-violet, but the maximum sensitivity is usually in the blue. Photographic image formation rests on a latent and lasting effect produced by light in microscopic silver halide crystals suspended in gelatin coated thinly on a glass, film, or paper base. The crystals affected by light are readily reduced to metallic silver by a suitable reducing agent or developer, and the unreduced silver halide is dissolved out with a fixer, usually "hypo," thus producing images composed of tiny silver grains, the density of which is a function of the intensity or total energy incident upon the emulsion. Although gelatin is highly transparent to waves longer than 3,000 A, it is strongly absorbent for shorter waves and practically opaque below 2,000 A. In order to record spectra below 2,000 A, in 1901 V. Schumann effectively eliminated the shielding effect of gelatin by depositing silver salts on glass plates with only enough gelatin to support them. Another way to circumvent the ultra-violet absorption of gelatin was discovered in 1921; it consists of coating an ordinary photographic plate or film with a thin film of oil or suitable organic substance that fluoresces in ultra-violet light and emits longer wave radiation not absorbed by the gelatin. (See Photography.)

In 1873 H. M. Vogel discovered that the light sensitiveness of silver salts could be extended to longer waves by bathing ordinary plates in certain dye solutions. By 1900 the incorporation of suitable photosensitizing dyes in emulsions produced panchromatic plates that were sensitive to the entire visible spectrum, and after 1930 the synthesis and application of an important series of polycarbocyanine dyes extended the sensitivity of photographic emulsions into the infra-red to about 13,000 A. Since large intervals of spectra and multitudes of spectral details could thus be recorded simultaneously it follows that more spectrographic observations have been made photographically than by all other methods. In addition to being applicable in an enormous range of wave lengths the photographic method provides a permanent, detailed record of a spectrum that can be conveniently examined or accurately measured by any number of persons as often as desired without repeating the experiment. Furthermore, photographic exposures are cumulative, and the photographic method thereby derives additional advantages in integrating the light from flickering or intermittent sources and in recording extremely faint images by giving long exposures. Although the absolute sensitivity of a photographic emulsion may vary considerably with wave length, it can often be regarded as constant over a limited range of spectrum, and in any case can be calibrated as a function both of wave length and intensity, thus providing a convenient method of measuring the relative intensities of spectral lines. This photographic-photometry method was developed' about 1925 for the purpose of testing quantum rules for the relative intensities of certain lines, and since 1930 it has become standard practice in quantitative spectrochemical analysis.

It should be emphasized that any selective receiver (eye, phototube or photographic plate) employed for measuring the relative intensities of spectral lines requires calibration by comparison with nonselective receivers (thermopiles, etc.).

## OBSERVATIONS AND MEASUREMENTS

Spectroscopic measurements are concerned essentially with energy distribution as a function of wave length. This function is characteristic primarily of the light source and secondarily of 21-G

on one side, one strip is shielded and the other is exposed to radiation. If the spectral intensity changes rapidly from point to point and experiences sudden inflections the spectra are called "discontinuous." Such spectra also may be either emission spectra, or absorption spectra; they usually consist of hundreds or thousands of lines. The division of observable spectra into continuous and discontinuous, either in emission or in absorption is a broad but useful classification. Each class contains an enormous number of examples, some of which may be grouped according to certain criteria into smaller classes. The following examples will illustrate the principal classes of spectra that are subjected to observation and measurement.

Emission Spectra.—All self-luminous sources yield emission spectra, which are of different types according to the nature of the light source. Spectrally dispersed light from glowing gas mantles, electrically heated metallic filaments, or hot molten metals are continuous over great ranges of wave lengths, and for "black body" radiation the wave length of maximum intensity is an inverse function of absolute temperature. It follows that such substances cannot be distinguished by means of their spectra so long as they remain in the solid or liquid state.

The effects are quite different when the substances examined are in a state of luminous gas or vapour. They then emit characteristic discontinuous spectra by which they can be uniquely identified, whether they are excited in the laboratory or in a celestial body far away. These spectra consist of bright lines or bands variously spaced on a dark background.

Line spectra are characteristic of atoms or ions, while band spectra originate in molecules. The former consist of a certain distribution of slit images of different intensity and usually of various types such as partially self-reversed lines, sharp lines, diffuse lines, unsymmetrical lines and complex lines with two or more components. Partially reversed or easily absorbed lines always indicate that the normal state or some low energy state of the atom or ion is involved. The relative sharpness or diffuseness of lines is determined by such factors as pressure, temperature, mass and excitation. Complexity of spectral lines is referred either to different isotopes of the same element (isotope shift) or to interaction of valence electrons with a spinning isotopic nucleus (hyperfine structure).

In a band spectrum a great number of fine lines are closely and regularly placed in each band, becoming more and more crowded near the band head. The band heads are on the shortwave side of the line groups in some band systems, and on the long-wave side in others. The differences between line and band spectra are illustrated in Plate I where fig. 12 and fig. 1b are portions of the line and band spectra respectively of nitrogen. Some bands are less regular in appearance, and others do not appear to be resolvable into lines. In pure gases the commonly observed band spectra characterize molecules consisting of two similar atoms, such as H2, He2, N2, O2. The line spectra of metals excited in flames, arcs or sparks operated in the free atmosphere are usually accompanied by band spectra characteristic of monoxides such as CaO, BaO, ScO, LaO, formed by the oxidation of the metals. Arc spectra frequently show band spectra identified with NO and CN as well as line spectra of N, O, A and C, the principal constituents of the atmosphere. Many dipole molecules unknown to ordinary chemistry but recognized spectroscopically are apparently formed only under special conditions existing in the light sources.

No two substances yield the same spectrum and consequently the chemical nature of substances can be determined spectroscopically. Thus glowing atomic hydrogen is characterized by a bright line in the red, besides progressively weaker ones of shorter wave length (see Plate I, fig. 6), and since these are exhibited by nothing but hydrogen, they serve to disclose the presence of atomic hydrogen wherever it occurs in the luminous state. Each of the known chemical elements has its distinctive family of

spectral lines, differing in distribution, relative intensity and total number, but always the same under the same conditions of excitation. The same element, however, under radically different excitation conditions will emit entirely different spectra. The most easily excited spectrum is that of neutral atoms in possession of all their valence electrons, but if the excitation is violent enough to remove one electron from each atom the resulting ions when excited radiate another characteristic spectrum. A third type of spectrum is emitted when the atoms are doubly ionized by removal of two electrons, and so on until only one outer electron remains. Thus each element or atom has as many characteristic spectra as it has electrons. In most arc or spark sources generating atomic spectra of a pure element two or more spectra appear simultaneously with one usually predominating (see Plate I, fig. 3a and fig. 3b). When two or more elements with comparable excitation characteristics are abundant in a light source each element emits its own spectra essentially the same as if all other elements were absent. The spectra of complex substances such as ores, minerals, metal alloys and chemical mixtures thus reveal simultaneously all the types of atoms and ions that are excited in the light source. Such supernumerary line spectra often have superposed on them band spectra of molecules formed and excited in the same light source as well as lines and bands of atmospheric elements, and in addition, a more or less intense continuous background which may be traced either to unquantized radiation from the atoms, to continuous spectrum from incandescent oxides in the light source, or to stray reflected or scattered light in the spectrograph, sometimes to all three. In such complicated cases it is obvious that only experienced spectroscopists can interpret the spectrograms correctly. Familiarity with the spectra of various elements often enables an experienced observer to identify lines or bands at sight for the distribution and relative intensities in certain groups are memorized and recognized in the same way that constellations are recognized among stars. In theory any unknown spectrum or mixture of spectra can be identified by comparing it with all the spectra of known elements excited under similar conditions, but in practice the endless labour of repeatedly observing the comparison spectra is avoided by measuring wave lengths corresponding to the unknown lines and comparing these with wave-length tables of identified lines compiled for this purpose.

For purposes of chemical identification the wave lengths and the relative intensities of lines in spectra may be regarded as constants of nature, but closer examination shows that in any given spectrum certain variations are produced by different excitation conditions. Thus spectral wave lengths are generally slightly increased as the total pressure of gas or vapour surrounding the radiating particles is increased. Such pressure shifts are further correlated with atomic diameters and with atomic energy levels.

Also the wave lengths are either decreased or increased, according to Doppler's principle (see Doppler Effect) when the radiating source approaches or recedes from the observer. In astrophysics this principle has disclosed the sun's rotation, the radial velocities of stars, and an apparently expanding universe, whereas in the laboratory it explains, when combined with the kinetic theory of gases, the intrinsic natural width of spectral lines as a function of  $\sqrt{T/M}$  in which T represents absolute temperature and M molecular weight. When standard wave lengths in the solar spectrum are measured it is necessary to correct the observations for Doppler effect due to the relative motion of the sun and the spectrograph.

Again, with few exceptions, all atomic spectral lines are split into three or more components when the radiating particles are in strong magnetic fields (see Zeman Effect) and similarly many lines either shift or widen or divide into resolved components when the radiating particles are subjected to strong electric fields. (See Stark Effect.)

From the general theory of relativity (q.v.) A. Einstein in 1917 concluded that wave lengths characteristic of atoms should increase in strong gravitational fields. This effect is quite inappreciable in the laboratory but it appears to be present in the

solar spectrum, and especially in the spectra of very dense stars. The most striking changes in relative intensities of lines belonging to a particular spectrum occur when excitation conditions favour the partial self-reversal of selected lines. These variations of spectral characteristics are highly objectionable in standard wave lengths and in spectrochemical analysis, but they are of primary importance in spectroscopic research since they yield information about atomic structure and the mechanism of radiation. Consequently, when truly invariable spectra are desired they may be produced by carefully specifying and reproducing the light source in such a manner that spectral variations are eliminated or minimized, but if atomic structure is being investigated it is desirable to effect the largest practicable changes in spectra and relate these to variations in the light sources. In any case it is evident that some means of accurately expressing the positions of lines in a spectrum is of primary importance.

Wave Lengths.-Measurements of spectra become directly comparable with each other only when they have been converted to the scale of wave lengths (or frequencies) of the radiations which produce the spectral lines. The credit for introducing this scale into spectroscopy is due to A. J. Angstrom who described the spectrum of the sun in terms of wave lengths in 1868, and since that time the positions of practically all known spectral lines have been expressed in wave lengths. The unit of wave length in spectroscopy is a ten-millionth part of a millimetre or 10-10 m. It is called the "angstrom" and is symbolized by A. In these units, the visible spectrum ranges from about 3,800 A (violet limit) to about 7,700 A (red limit). Extremely short waves, in particular those observed in Roentgen or X-ray spectra which range from about 0.1 A to about 100 A, are more conveniently expressed in still smaller units, and for this purpose the X unit, approximately 1/1,000 A, is generally used Similarly, very long optical waves, in particular the far infra-red heat waves, are more conveniently expressed in larger units, and for this purpose the micron,  $\mu = 10,000$  A, is commonly used Summarizing:  $10^{-6}$ m. = 0.001 mm. =  $1\mu$ = 10.000 A = 10.000,000 X Wave lengths ranging from 6 A to 5,000,000 A have been measured in spectra associated with valence electrons but these limits will surely be extended in both directions. Absolute wave lengths cannot be determined directly from prisms but have been measured with gratings and interferometers by methods outlined in the discussion of these instruments. Because such measurements are relatively difficult and tedious they have been made only for the purpose of setting up standards of wave length, and in all other spectroscopic work, whether with prisms or gratings, wave lengths are deduced by interpolation between adopted standards

Wave Numbers .- In the interpretation of spectra as transitions between quantized energy states  $(E_2-E_1=h\nu)$ , it is necessary to express the positions of the spectral lines on a frequency, v, scale instead of a wave-length scale. Unfortunately, neither nature nor human ingenuity has disclosed a method of directly measuring the oscillation frequencies corresponding to light waves. These frequencies, defined as the number of waves that pass a given point in one second, must be derived from the relation  $\nu = c/\lambda$  in which c is the velocity of light and  $\lambda$  is the observed wave length. In order to make these frequencies independent of the medium through which the light passes both c and  $\lambda$  must be evaluated in vacuo. Since the velocity of light is very great (25,-977,600,000 cm. per second) and a light wave is very small (0.00000550 cm. for brightest visible light) the frequency is an extremely large and awkward number (545,000,000,000,000 in this example). In spectroscopy it has become common practice to replace the ungainly actual frequencies by "wave numbers." representing the number of waves in one centimetre of vacuum and symbolized by cm.-1. If the wave length has been measured in air it must be multiplied by the refractive index of air to change it to its value in vacuo. In 1926 H. Kayser prepared his Tabelle der Schwingungszahlen for the convenient conversion of wave lengths in standard air to wave numbers in vacuo. For example 5,500,000 A=18,176.781 cm.-1. Such wave numbers of observed spectral lines are strictly proportional to the natural frequencies and to the corresponding changes in atomic or molecular energy.

Standard Wave Lengths.—In modern spectroscopy the primary standard of wave lengths is that of the red radiation from cadmium vapour first measured relative to the international metre bar by interferometer methods in a classical experiment by Michelson in 1892. (See Interprementer) Benoit, Fabry and Perot, in 1905, found that 1 metre contained 1.553,164 13 of these waves and the reciprocal of this number has been internationally adopted as the definition of the primary standard: "the wave length of the red ray of light from cadmium is 6,438.4696 angstroms in dry air at 15° C. on the hydrogen thermometer, at a pressure of 760 mm. of mercury, the value of g being 980.67 (45°)." The probable error of this absolute value is of the order of 1 part in 16,000,000, i.e., somewhat less than the least error in the intercomparison of two metre bars.

A half century of intensive study of the spectra of natural elements proved that the red radiation from cadmium vapour is orobably the best primary standard that nature provides, but in 1940 W. Wiens and L. Alvarez demonstrated that a pure artificial isotope of mercury (Hg<sup>188</sup>) obtained by bombarding gold (Au<sup>197</sup>) with neutrons probably presents a superior primary standard. It is not unlikely that a progressive world will some day adopt the wave length of green radiation (5,461 A) from Hg<sup>188</sup> as its most convenient, constant, indestructible, accurately definable, and reproducible fundamental standard of length.

A method of measuring, with high accuracy, the ratio of two different wave lengths was outlined in principle in our brief discussion of the Fabry-Perot etalon interferometer. After 1907 this method was used in several laboratories to determine, relative to the primary standard, the wave lengths of selected lines which might serve as secondary standards. The wave lengths of several thousand atomic radiations characteristic of helium, neon, argon, krypton, xenon, iron, titanium in laboratory spectra, and well over 1,000 lines in the sun's spectrum, have thus been measured, but only such mean values are accepted as secondary standards by the International Astronomical union as have been independently and concordantly measured in at least three laboratories. For example, in the iron spectrum interferometric measurements have been made on thousands of lines with wave lengths ranging from 2,101 A to 10,216 A but only 306 secondary standards ranging from 2,447 A to 6,677 A have been adopted. These iron secondary standards are believed to be accurate within ±0.001 A but to insure their reproducibility the source is carefully specified as "the Pfund arc operated between 110 and 250 volts, with 5 amperes or less, at a length of 12-15 millimetres used over a central zone at right angles to the axis of the arc, not to exceed 1-1.5 millimetres in width, and with an iron rod 6-7 millimetres diameter as the upper pole and a bead of iron oxide as the lower pole." The International Astronomical union has also adopted as tertiary standards the wave lengths between 3,371 A and 6,750 A of 312 iron lines derived from secondary standards by grating or interferometer interpolation. In the absence of official standards in the extreme ultra-violet, spectroscopists have been forced to use preliminary values obtained by the coincidence method of overlapping orders in grating spectra or by direct calculation from spectral series formulae or from spectral terms accurately determined from longer waves.

Interpolation of Wave Lengths.—The wave lengths corresponding to lines in any spectrum whatsoever are readily determined by interpolation between standards, provided that the spectrum of the international iron arc is recorded with the same spectrograph. For this purpose the spectrum of the source under examination is photographed through one portion of the slit, and the arc spectrum of iron through one or both of the adjacent portions, so that two spectra in juxtaposition, or slightly overlapping, are obtained as illustrated in Plate I, fig. 5. For accurate determinations the relative positions of spectral lines and standards are measured with a micrometer or comparator consisting of an accurate screw designed to translate the spectrogram under a microscope so that the lines and standards are brought successively into coincidence with a reticle. The positions of the lines are then read from a scale which indicates complete turns of

the screw, and a divided drum head which registers fractions of a turn

In prismatic spectra the dispersion increases rapidly as the wave length diminishes, and linear interpolation will not give correct results. Approximate values of wave lengths may be obtained by interpolation on a graph of dispersion versus wave length constructed by plotting scale readings of standard lines as abscissae and wave lengths as ordinates. The most accurate method of determining wave lengths in prismatic spectra is by mathematical interpolation with the Hartmann dispersion formula which gives a simple relation between wave length,  $\lambda$ , and linear scale reading, r.

$$\lambda = \lambda_0 + \frac{c}{r - c_0}$$

where  $\lambda_0$ , c, and  $r_0$  are constants which can be evaluated from the solution of three simultaneous equations containing three known wave lengths or standard lines and their corresponding scale readings.

Relative wave lengths are most readily obtained from diffraction spectra since linear interpolation between standards is justified by the fact that the dispersion is constant or nearly so, in a given grating order or setting. If  $r_i$  and  $r_f$  are millimetre scale readings for initial and final standards,  $\lambda_i$  and  $\lambda_f$ , on a spectrogram, the dispersion  $d = (\lambda_f - \lambda_i)/(r_f - r_i)$  A per mm. The product of this dispersion constant and  $r_i$  subtracted from  $\lambda_i$ gives a constant \(\lambda\_0\) which, on any calculating machine, can be automatically added to any  $d \cdot r_x$  and the final result is  $\lambda_x = \lambda_0 +$  $d \cdot r_m$ . Both in prismatic and in grating spectrograms intermediate standards should be measured, in the former case to test the fit of the dispersion formula and in the latter to test the normality of the spectrum. If the calculated values deviate from the true standards a plot of such deviations will reveal the proper corrections to apply to the wave lengths calculated for the other measured lines. Under the most favourable conditions such interpolated wave lengths are probably correct within a few thousandths angstrom. All wave-length measurements relative to iron standards are obviously facilitated by reference to a good photographic map of the iron-arc spectrum permitting instant identification of the standards. A small portion of such a map is reproduced in Plate I, fig. 4.

Intensity Measurements.-The exact determination of relative intensities of the various parts or lines of a spectrum is in most cases as important as exact wave-length measurement but this phase of spectroscopy had a tardy development, partly because of experimental difficulties and partly because the important applications were mostly unrecognized before 1025. Only heat-absorbing detectors show a linear and nonselective response to spectral intensity and since they are naturally inefficient heat engines their use has been restricted mainly to infra-red spectra. All other detectors, being nonlinear and selective, require calibration but this is a complicated and difficult operation, especially in the extreme ultra-violet where heat detectors are relatively insensitive. Consequently, even the most modern tables of identified spectral lines contain only rough estimates of line intensities on arbitrary scales which differ from spectrum to spectrum and frequently from region to region in the same spectrum. These arbitrary intensity scales usually represent visual estimates of photographic blackening and they range from I to IO or I to 1,000 or 1 to 10,000. Such estimates have no definite meaning and no truly quantitative value.

After 1925 the need for accurate measurements of spectral line intensities was stressed by the new quantum theory of atomic spectra and by a rebirth of quantitative spectrochemical analysis. Mathematicians predicted important relationships between line intensities and multiplet structures or quantum numbers, and experimental spectroscopists promptly devised methods of testing the theory. Simultaneously in applied spectroscopy quick methods of accurate chemical analysis based on the measurement of spectral-line intensity ratios were empirically developed. Since almost all spectroscopic observing was done photographically the quantitative determination of intensities from spectrograms required

the construction and use of suitable microphotometers or microdensitometers to measure the photographic densities of spectral line images. By making a series of exposures of known ratio, either in intensity or in time, photographic density as a function of radiation intensity of a given wave length can be determined for the particular type of photographic emulsion employed, and from density measurements at different wave lengths in a comparison spectrum of known energy distribution true intensity ratios can be deduced. Standard sources of known energy distribution are found in the black body or in metal-filament lamps operated at specified colour temperatures. Photographic sensitivity and contrast may be regarded as constant in narrow spectral regions such as those encompassed by compact multiplets, hyperfine multiplets, Zeeman patterns or close line pairs, and in these cases relative intensities of component lines are determinable without spectral energy calibration.

minable without spectral energy calibration. Absorption Spectra .- In 1859 G. Kirchhoff gave mathematical and experimental proof of the following law: "The ratio between the powers of emission and the powers of absorption for rays of the same wave length is constant for all bodies at the same temperature." From this it follows that a transparent body cannot emit light, and one that radiates a continuous spectrum must be opaque. Further, a gas that radiates a line spectrum will absorb the lines which it radiates at the same temperature. For example, lines observed in laboratory arcs as emission spectra of 66 elements or compounds have been identified as absorption lines in the spectrum of the sun. As a consequence of Kirchhoff's law practically everything that has been said about emission spectra applies also to absorption spectra. There are, however, some experimental conditions that permit molecular identification and quantitative chemical analysis by means of absorption spectra that cannot be duplicated in emission spectra. Thus in the analysis of inorganic compounds (salts, minerals, etc.) by emission spectra the light sources (flames, arcs, sparks) commonly used for exciting the spectra completely dissociate the compounds revealing intense spectra of the metallic atoms and of unstable compounds formed in the light source, whereas the spectra of the halogens or radicals are either unobserved or masked. Thus, essentially the same atomic emission spectrum is observed with various metallic compounds (halides, oxides, carbonates, sulphates, etc.). Similarly organic molecules (tissues, dyes, etc.) are atomized by the heat and excitation of emission sources, revealing only spectra of metallic impurities that may be present, while the emission spectra of carbon, hydrogen and oxygen are indistinguishable from those emitted by atmospheric constituents, dissociated carbon dioxide and water vapour. In many cases, however, inorganic compounds in solution and organic compounds in general exhibit characteristic absorption spectra which distinguish them from each other. Since absorption spectra of compounds are observed at relatively low temperatures the molecules are stable and unimpaired, but since the substances are then usually in a liquid or solid state, rather than in a gaseous state, the absorption will depend on the energy content of the molecules and on the perturbing effects of surrounding molecules. These absorption spectra therefore usually consist of one or more broad bands in which the energy distribution is characteristic of the compound. If an unknown mixture contains two or more absorbing compounds their identity and relative amounts can be determined if the absorption bands are sufficiently different in wave length and accurately defined to permit an estimation of their relative intensities. Extraordinarily narrow absorption bands, almost linelike, are exhibited by solids, solutions and glasses containing atoms that possess one or more f-type electrons ("rare earths" with atomic numbers 58 to 71 and 91 to 96). This is illustrated in Plate I, fig. 2a, by glass coloured with salts of neodymium, atomic number 60. A typical example of true line absorption is shown in Plate I, fig. 2b, which represents the appearance of a continuous spectrum after passing through a column of atomic potassium vapour. Narrow lines belonging to molecular spectra of oxygen (O2) and water vapour (H2O) are readily observed in absorption but not in emission. Red and infra-red bands of these molecules invariably appear

on spectrograms made in the laboratory with long focus spectrographs provided that the light source emits a continuous background, and they are outstanding features of the solar spectrum especially when the sun is near the horizon and shines through the thickest layer of terrestrial gas and vapour. Similarly, because of the great depth of absorbing vapours in the solar atmosphere the atomic spectrum of iron is much more fully revealed in the Fraunhofer spectrum than has been observed in laboratory emission spectra.

#### APPLICATIONS

The principal applications of spectroscopy are to (1) chemical and physical analysis, (2) research on atomic structure and the mechanism of radiation and (3) investigations of some properties of atomic nuclei.

Spectrochemical Analysis.—That a system of qualitative chemical analysis could be based on spectroscopic observations was first convincingly demonstrated by Kirchhoff and Bunsen who (1860) applied spectroscopy to the discovery of two alkali metals (Rb and Cs) and to the identification of chemical elements in the sun. Save for chemical analysis of meteorites that fall to earth there is no way to lean anything concerning the chemical and physical conditions of celestial bodies except from an analysis and interpretation of the light those remote bodies emit. Consequently the challenge and urge to apply spectroscopy to astronomy was irresistible, and an amazing accumulation of information on the radial motions, chemical compositions, and physical conditions of planets, comets, stars and nebulae now constitutes the science of astrophysics (q,v.).

In terrestrial laboratories the application of spectroscopy to chemical analysis has always had to compete with conventional chemical methods and progress was slow until precise photographic photometry was introduced about 1925, whereupon quantitative spectrochemical analysis quickly became common practice throughout the world. It is readily observed that when one element is progressively diluted in another the spectra of the diluted element become progressively weaker and simpler until they finally vanish when the concentration is less than the limit of spectroscopic detection. Under specified conditions of observing, these partial or residual spectra may be correlated with the known composition of synthetic mixtures or standards and thus provide criteria for the quantitative estimation of comparable unknowns. This is essentially the principle of spectrochemical analysis as first applied to solutions by W. N. Hartley about 1880, to fused salts by A, de Gramont about 1900 and to metal alloys after about 1920. In 1925 W. Gerlach showed that unavoidable fluctuations in light sources and spectrum photography could be largely eliminated by referring the intensity of an impurity line to a neighbouring line of the major component as standard. In the spectrum of any alloy or mixture of known composition, one or more pairs of lines can usually be found in which a strong (analysis) line of a minor constituent has the same intensity as a weak (internal standard) line of the major constituent. When such homologous pairs are found in spectrograms of samples containing different but known amounts of the analysis element, the concentration of this element in other samples is found by intercomparing the line pairs and selecting the one in which the two lines are of equal intensity. A further improvement of this internal-standard method resulted from the use of only one pair of lines the relative intensities of which in known samples are determined by photometric tensities of which in known samples are determined by photometric measurements, and plotted as a function of concentration of the analysis element. If he two variables are plotted on logarithmic scales, the resulting analytical curve is usually a straight line with slope about 1. After preparing such a calibration graph for each analysis element any sample of comparable composition is easily analyzed by measuring line-intensity ratios and reading concentrations from the graphs. An meaninessly ratios and reating contentrations from the graphs. An excellent description of the preparation of samples and standards, spark excitation of spectra and analytical procedure can be found in Spark Spectrographic Analysis of Commercial Tin, published (1942) by B. F. Scribner as Research Paper 1,451 of the national bureau of standards, U.S. department of commerce. Similar procedures have been perfected for the analysis of iron alloys, aluminum alloys, magnesium alloys, brasses, bronzes, type metal, and practically all other types of metallic compounds. Careful chemical calibration and photographic photometry have reduced routine analytical errors to 1% or 2% of the amount present, and the time required for a complete analysis of a sample has been reduced to ten minutes or less. Since most of the time

required for such an analysis is consumed in procuring and measuring a photographic spectrogram, claborate spectrographs have been constructed with 12 photoelectron multiplier tubes to receive light from an intenal standard line and from 11 different analysis lines. Radiant energies received by these phototubes are amphified to actuate indicators calibrated in percentage composition thus permitting simultaneous and almost instantaneous determination of 11 elements. For composition control of metals and alloys in production, spectroscopy has suipassed chemistry in speed, sensitivity and accuracy of analysis. It must be remembered, however, that no satisfactory absolute method of spectrochemical analysis has been devised; all the practical methods by 1047 were relative to synthesized standards or chemically analyzed samples which serve for spectrographic calibration.

1947 were relative to synthesized standards or chemically analyzed samples which serve for spectrographic calibration.

Emission spectioscopy has also found extensive application to analytical problems in agricultural, biological and pathological chemistry, in mineralogy and geochemistry and in archaeology and climinology. In these problems the samples are often in highd or powder form which can be vaporized and excited to emit spectra either in hot flames or in electric arcs or sparks between electrodes of pure carbon. Usually a definite amount of some suitable element is added to supply internal standards and then the calibration and analytical procedures are essentially the same as for solid metal samples.

Empirically it is found that operating with beth sources at atmos-

Empirically it is found that operating with light sources at atmospheric pressure and with spectral detectors sensitive between 2,000 and 9,000 A at least 70 chemical elements can be readily determined by emission spectroscopy. This is related to the fact that these elements have ionization potentials less than ten volts and their strongest lines have wave lengths between the limits mentioned. Gaseous elements have higher ionization potentials; their strongest lines are in the far ultra-violet and their spectra are fully developed only at reduced pressure in Gessler tubes. In principle, everyone of the 50 chemical elements can be detected and determined by means of emission spectra, provided that proper sources and spectrographs are emission spectra, provided that proper sources and spectrographs are emission spectra, provided that proper sources and spectrographs are emission spectra.

son spectra, provided that proper sources man spectrage properties and of Atoms.—Because atomic spectra appear, generally, to consist of a random distribution of lines of different intensities, a century elapsed between the discovery of spectral lines by Fraunhofer and a fruitful clue to their physical interpretation by N Bohr (1913). Then in little more than a decade an amazing development in analysis and theory of spectral structure made all spectra interpretable in terms of atomic properties and, conversely, permitted the deduction of atomic structure from observations on spectra.

Hydrogen is the lightest atom and possesses the simplest spectrum; in the visible it consists of a regular succession of lines with ever closer spacing and decrement of intensity in the direction of shorter wave lengths (see Plate I, fig. 6). In 1885 J. J. Balmer discovered an extremely simple mathematical relationship between these 1H lines. Expressed in wave numbers the Balmer formula gives  $\nu=R/2^2-R/n^2$ , where the constant R=100,677,8 cm<sup>-1</sup>, and  $n_1$  represents the integers 3, 4, 5 . . . . . This Balmer series begins with 6,562 A and ends at 3,646 A. Similar 1H series were later found in the extreme ultraviolet,  $\nu=R/1^2-R/n^2$ , by T. Lyman, and in the infra-red,  $\nu=R/3^2-R/n^2$ , by F. Paschen, All possible H series can be accurately represented by one formula,  $\nu=R/n^2-R/n^2$ ; where  $n_2$  and  $n_1>n_2$  are integers and  $n_2$  is constant for a given series. Thus the wave number of any H line can be expressed as the difference of two quantities, the larger being a constant term called the limit of the series, whereas the other varies from line to line and is known as the running term.

other varies from line to line and is known as the running term. In 1889 J. R. Rydberg reported finding series in the spectra of alkali (Plate I, figs. 8, 9) and alkaliane earth elements (Plate I, figs. 70), and notwithstanding the imperfect data then at his disposal he discovered most of the important properties of spectral series. From certain characteristics of the lines he distinguished three species of series, principal, sharp and diffuse, superposed in the same spectrum, and he recognized that the members of each series were double for alkaline (7 Li, 1x Na, 19 K) and either single or triple for alkaline earths (12 Mg, 20 Ca, 30 Zn). Rydberg found that each series could be represented in wave numbers by a formula of the type  $v = L - \frac{R}{R}$ . In which L is the L-in the state of the series where L is the L-in the state of the series of the seri

 $\frac{n}{(m+\mu)^3}$ , in which L is the limit of the series, R the Rydberg constant (practically identical with R in the Balmer formula) and m has successive integral values to which a constant fractional part,  $\mu$ , is added. A fourth type of series was discovered in 1907 by A. Bergmann, and because it was more hydrogenlike ( $\mu \approx \infty$ ) than the others it came to be called fundamental. Rydberg also indicated that the difference between the limit of the P series and the common limit of the D and S series is equal to the wave number of the first line of the P series, and C. Runge in 1908 pointed out a similar relation between the D and F series, so that all the different series were interconnected. An abbreviated notation was then adopted for the four basic types of series:

Principal, v=n S-m P Sharp, v=n P-m S Diffuse, v=n P-m D Fundamental, v=n D-m F

where n stands for a simple integer, and m for appropriate integers

plus µ. In order to distinguish the components of doublets and triplets from each other it was necessary to add subscripts to these term symbols. In addition to the regular scenes others were detected when the limits were changed and still others between singlet and triplet terms (Ritz combination principle). Thus it appeared that any given term might combine with many others, and although two terms were necessary for each observed line the total number of terms required to represent any spectium completely might be much smaller than the total number of lines.

In 1944 A. Fowler found ionized belium atoms (2 He\*) characterized by a hydrogenlike series except that the Rydberg constant R required multiplication by 4 He also discovered, in the spark spectra of 12 Mg\*, 20 Ca', and 38 Sr\*, series of doublets resembling the P, S and D doublets of alkalis, but with 4 R in their formulas. By 1949 the regularities detected in vanous spectra sufficed to suggest two general laws: (1) the alternation law which states that even and odd multiplicities of terms alternate in successive columns of the periodic system (2) the displacement law which states that the spectrum of an ionized element resembles that of the neutral element preceding it in the periodic system (see Plate II). Term multiplicities of atoms or ions are thus determined solely by the number of electrons, whereas the atomic charge affects the position of the spectrum. These facts suggested a direct connection between spectral lines and the electrons and protons in atoms

suggested a direct connection between spectral lines and the electrons and protons in atoms.

In 1913 N. Bohr proposed two fundamental postulates, viz, that atomic stationary states exist, and that the radiation frequency is equal to the energy difference of two states divided by Planck's constant (h=6.64 x to-2" erg sec.) The empirically established spectral terms must therefore be interpreted as quantized stationary energy states characteristic of atoms and ions. The rapid development of the quantum theory of radiation constitutes one of the most thrilling chapters in the history of science (sec QUANTUM MECHANICS).

Quantum Numbers and Atomic Energies,—Omitting further review of historical and experimental details the following discussion is restricted to a vector model of the Rutherford-Bohr atom (see Atom) which is assumed to consist of a tiny but massive

Quantum Numbers and Atomic Energies.—Omitting flurther review of historical and experimental details the following discussion is restricted to a vector model of the Rutherford-Bohr atom (see Arom) which is assumed to consist of a tiny but massive nucleus (composed of protons and neutrons) around which circulate one or more electrons. The maximum number of electrons in any atom is expressed by its atomic number, Z (identical with the number of protons in its nucleus), and this number langes from 1 for H, the lightest, to 92 for U, the heaviest element in nature. These electrons move in imaginary orbits about the nucleus at average distances represented by a principal quantum number, n, which in turn numbers the successive shells of the periodic system and serves as a coefficient to the term symbol, S, P, D, F, etc. A sequence of n term values subtracted from a limiting term gives the wave numbers of lines in a spectral series. In most cases an electron jump from one shell or value of n to any other shell or value of n constitutes the largest change in energy that can occur in a given atom. If an electron is moved from its lowest value of n to n= 5 the atom is lonized, and the energy required to accomplish the removal of an electron is called the ionization potential. This energy is usually expressed either in wave numbers (cm.²) or in electron volts (ev.); in the case of 1H it is 109,677.58 cm.² (the Rydberg constant) or 1395 ev. (See Table VIII.) Hydrogen-lik (the Rydberg constant) or 1395 ev. (See Table VIII.) Hydrogen-lik the spectra are also emitted by ionized helium (21E°), by doubly ionized lithium (31E°), by terobly ionized benyllium (48e\*\*), etc., but the spectra are as shifted successively toward higher frequencies, because the energy of electron orbits as a function of n is proportional to 27/4°. It follows that for 24He' the separation energy of the remaining electron from the lowest level (the ionization potential) will be 4 times that for the 1H atom; for 3Li\*\* it will be 9 times as great and for 4B

3LN' it will be 9 times as great and for  $48e^{-1}$  to times. The next largest change in atomic energy (after that due to a change in n) is usually that associated with a constant orbital angular momentum of the optical electron. This momentum is pictured as a vector of magnitude 0, 1, 2, 3, ... in  $h/2\pi$  units; it is called the azimuthal quantum number and is symbolized by l. The numerical values of l=0, 1, 2, 3, ... correspond respectively to the empirical rem symbols, S, P, D, F, ... originally abbreviated from the different types of series first found in the spectra of alkali atoms. Electrons with l=0 are called s-electrons; those with l=1, P-electrons; those with l=1, P-electrons. It may be interjected here that these four l values and the first seven n values suffice to describe the normal electron configurations of all possible atoms and ions. When two or more optical electrons are present their individual orbital momenta, l,  $l_0$ , ... are added vectorially to form a resultant  $L_p$  but quantum theory dictates that such a resultant and l at the possible resultant L values are  $L = (l_1 + l_2)$ ,  $(l_1 + l_2 = 1)$ ,  $(l_1 + l_2 = 1)$ . The vector addition for this case, is shown graphically in fig. 13. If all but one of the l are zero, the resulting L values of two electrons and ther combining each of the resulting L values with the l of the third electron. The term types given by various simple electron configurations are shown in Table I.

Quantum theory and observation prove that an important selection rule controls atomic energy changes resulting in radiation—viz., the greatest intensity of emission results when  $\Delta L = \pm 1$ . In addition, when the interaction of the elections is small, only those quantum transitions take place for which only one of the electrons alters its I value in accordance with the selection rule.  $\Delta I = \pm 1$ . Notwithstanding these simple jules, many spectra exhibit lines corresponding to

ing these simple rules, many spectra exhibit lines corresponding to L=0,  $\pm z$ ,  $\pm z$ , as well as to double-electron jumps. A third contribution to the total energy of an electronic system comes from the rotation of each electron about its own axis. This axial angular momentum has the same magnitude for each electron  $s=\frac{1}{2}(h/2\pi)$ , it is usually called the electron spin. When two or more electrons are present, the individual spin vectors  $s_1$  combine with each other to yield a resultant S (just like the  $l_1$  combine to form L). Analogous to L, the resultant spin S can take only certain discrete values, the maximum being obtained when all the  $s_2$  are parallel, and the minimum being one-half or zero according as the number of the minimum being one-half or zero according as the number of

electrons is odd or even.

The spinning electrons, and their resultant spin vectors S, account The spinning electrons, and their resultant spin vectors S, account for the spinting of most spectral terms into two or more components, and piovide a physical meaning for the subscripts (linear quantum numbers) originally attached to components of polyfold terms. The total angular momentum J of an atom is the vector sum of the resultant orbital angular momentum L and the resultant axial angular momentum S. According to quantum theory, L and S can angular momentum s. According to quantum theory, 2 and 3 can be oriented to each other only in certain directions, and therefore only certain discrete values of the resultant J are possible. The largest and smallest values of J result from simple addition and subtraction of L and S, while all intermediate values of J that differ by integral amounts are allowed. That is:

$$J=(L+S), (L+S-1), (L+S-2), \ldots |L-S|.$$

This rule is illustrated graphically for simple cases in fig. 44. When L>S, it is obvious that the number of permitted I values for a given value of L is z3+x. On the other hand, if L<S, the number of permitted I values for a given L is L+x. Thus, for S terms (L=0, zL+1=1) there is only one value of I, viz., I=S. Similarly, for P terms (L=1, zL+1=3) the number of components can never exceed three. However, for a great majority of terms L>S and for all these the possible number of components or term multiplicity I is equal to 2S+1. The empirically indicated alternation law follows directly from this result is nee the maximum multiplicity will be even directly from this result since the maximum multiplicity will be even

or odd according as the number of electrons is odd or even. In general, atomic energy states with different S are not expected to combine with one another because of a selection rule  $\Delta S = 0$ , but intersystem combinations are found to be fairly abundant and intense, especially as the atomic number increases. Table II displays the resultant S values and possible multiplicities for different numbers of electrons, (See also Plate II, figs. 1, 2, 3, 4.)

The total angular momentum of an atom can have integral or half integral  $J(h/2\pi)$  values because  $s=\frac{1}{2}(h/2\pi)$  for each electron. Furthermore, different sets of J values are associated with the same type of term (same L value) in systems of different multiplicity, because S is different, and finally, different sets of J values apply to different terms in the same multiplicity system because J=L+S. Since J represents the total angular momentum it is the most important quantum number for the fine-structure or multipliet analysis of atomic and ionic spectra. It has a perfectly definite physical meaning and quantitative value under all circumstances. Atomic energy changes are rigorously regulated by a simple selection rule, viz.,  $\Delta J = 0, \pm 1,$  recept that all 0 to 0 transitions are prohibited. Since the a priori probability that an atomic energy state exists is expressed by its statistical weight aJ+1, t its obvious that J is important for the relative intensities of spectral lines. The J values that belong to a few

different spectral terms in different multiplicity systems are shown in Table III

For any given spectrum in which energy levels have been established, relative values of J attached to the levels are readily determined from their combining properties and the selection rule.

$$\begin{vmatrix} I_{1-2} \\ I_{2-1} \\ I_{2-1} \end{vmatrix} = \begin{vmatrix} I_{2-1} \\ I_{2-1} \\ I_{2-1} \end{vmatrix} = \begin{vmatrix} I_$$

FIG. 13 --- VECTOR ADDITION OF OR-BITAL ANGULAR MOMENTA  $I_1=2$  and  $I_2=1$  to give resultants L=3,

L=3 o,±1. In spectra resulting from terms of odd multiplicity the absothe value of J is fixed by the absence of the transition J=0 to J=0 which is forbidden. In other cases, the absolute value of J can be deduced from the multiplicity and type of term if these are un-

2, 1 and type of term it these are un-ambiguous, as, for example, in mul-tiplets which are sufficiently law-abiding so that the terms can be identified from the sum rule (the sum of the intensities of all the lines of a multiplet which belong to the same initial or final state is proportional to the statistical weight 2J+1 of the initial or final state respectively), or from the interval rule (the interval between two successive components, J and J+1, of a polyfold term is proportional to J+1). Analysis of the more complex spectra is usually hopeless without the aid of Zeeman effect, i.e., the splitting of the lines into polarized components when the source of light is placed in a strong magnetic field. The total angular momentum J is space-quantized in a magnetic field and can assume 2J+1 discrete values which are differentiated by magnetic quantum numbers M. The magnitude of the level sphtting is the same for all singlet levels (normal Zeeman effect) but differs for all other terms according to the values of L and J (anomalous Zeeman effect). From any completely resolved Zeeman pattern the J values of the two combining levels are deduced at once from the number of components and the L values are simultaneously derived from the separations of the components since the splitting factors

FIG. 14.-VECTOR ADDITION OF ORBITAL MOMENTUM L AND AXIAL MO-MENTUM S FORMING RESULTANTS J FOR 8P, 3D, 4P AND 4D TERMS

4D7/2

have been accurately given empirically and by the quantum theory (see ZEEMAN EFFECT)

Summarizing the above discussion of quantum numbers we find that any atomic energy level (spectral term) is completely specified by four quantities: (1) its principal quantum number n which indicates the electron shell or period which the optical electron occupies; (2) its type—S, P, D, F, etc. where the capital letters stand for azimuthal quantum numbers or orbital angular momenta L=0, 1, 2, 3, etc., respectively; (3) its inner quantum number or total angular momentum I (written as a suffix or subscript to the term type symbol); and (4) its multiplicity number, r=2S+1, written as a superior prefix to the term type symbol. Thus  $4^3D_2$  represents the middle component (I=2) of a D term (L=2) in a triplet system (r=3) for which the principal quantum number n=4. Theoretically, the energy difference of two terms appears as intense radiation only when  $\Delta L=\pm x$ ,  $\Delta I=0$ ,  $\pm x$ ,  $\Delta I=0$ , and the two terms are of opposite parity, i.e., odd and even (Laporte rule). Typical energetic relationships of spectral terms and combining properties of the levels are shown graphically in fig. 15 which represents the spectrum of neutral mercury atoms. azimuthal quantum numbers or orbital angular momenta L=0, 1, 2, mercury atoms.

Pauli Exclusion Principle.-Having found an electronicquantum interpretation of spectral terms it is next in order to seek the connection between spectral terms and atomic structure. In order to understand the building-up of the periodic system (see Periodic Law, Tels, and account for stuking periodicities in atomic properties it is necessary to introduce a new assumption, known as the Pauli exclusion principle, which states that. "in one and the same atom, no two electrons can have the same set of values for the four quantum numers, n, l, m, and m, n." Table IV shows the electron shells and subgroups that are possible for atoms as a consequence of this exclusion of the properties of the second of the s to understand the building-up of the periodic system (see Periodic principle. The n cells are divided by l and the l cells are further divided by mi and by me, but instead of inserting the last quantum numbers

the presence of an electron in a (n, l, m) cell is represented by arrows pointing up or down according as  $m: j \mapsto j$  or -j. Only two electrons can be meach such cell, and then only when they have antiparallel spin directions, since otherwise these two electrons would have the same four quantum numbers  $n, l, m_l, m_s$ . The maximum number of electrons that can have the same n and l is given by the number of arrows in the corresponding cells. This number is equal to 2(2l+1), since 24+1 is the number of possible  $m_1$  values for a gave 1/2+1/5 since 24+1 is the number of possible  $m_1$  values for a given 1/2+1/5 since 1/2+1/5 ties when arranged in atomic number sequence. Naturally the electron configurations of atoms in their lowest possible energy states, and the corresponding spectral terms, will show a periodicity, since, after a certain number of electrons of a given type have been added, the

outermost electron will be once more, for example, an s-electron. The spectral terms describing ground states of atoms may be deduced from assumed electron configurations by adding together the l and s moments of the individual electrons, but first it is necessary to make an assumption about the mutual coupling or interaction of the individual vectors. The coupling that seems to be most common is called LS coupling; it may be expressed symbolically:

$$(l_1, l_2, \ldots) (s_1, s_2, \ldots) = (L, S) = J.$$

(ii,  $t_2, \ldots$ ) (s<sub>1</sub>,  $s_2, \ldots$ ) = (L, S)=J. This means that the individual I, vectors are strongly coupled to produce resultant L values of different energies, and the individual s, vectors are also strongly coupled to produce resultant S values of different energies. The resultants L and S are then less strongly coupled with one another and their resultant is J. Other types of electron coupling, in particular ji coupling, cour relatively rarely, but coupling intermediate between LS and ji is found more frequently, especially among excited states of heavy elements. However, because LS coupling applies to all the lighter elements, predominates in many others, and is either accurately or very approximately valid for the ground states of all atoms and ions it forms the basis for the standardized notation for spectral terms. ardized notation for spectral terms.

The spectral terms arising from nonequivalent electrons (belonging to different n, l groups of Table IV) may be obtained, in simple cases, by adding the L values of Table II. For example, two nonequivalent p electrons, pp, yield (L=0, 1, 2) S, P,

TABLE V .- Terms of Nonequivalent Electrons

Electron Configurations	Terms (omitting J values)	
ss sp pp pp dd d ss ss ss ss sp sp sp etc.	S. 18 T. 19	

present) have L=0 and S=0, and therefore always present the S=0 state. Closed shells can therefore be ignored when deriving the terms given by any electron configuration Furthermore, 'So for a closed shell must result when the shell is divided into two parts, the term types for each part derived, and the resulting angular momentum vectors added together. For example, adding the angular momenta of  $p^2$  electrons to the corresponding quantities for  $p^4$  electrons will give

etc.	

the resultant for  $p^6$  electrons, ie,  ${}^1S_0$ . From this it follows that L and S must be the same for these two electron configurations, and the terms arising from  $p^4$  are the same as those from  $p^2$ . Similarly,  $d^6$  gives the same terms  $as^2 d^4$ ,  $f^{12}$  the same as  $p^2$ , etc. In general, any subgroup lacking one or more electrons to fill the group behaves spectroscopically as if the lacking electrons alone were present, except that the terms are regular (smallest J level has least energy) when the group is less than half filled but inverted when more than half filled. Finally, of the terms given by equivalent electrons, those with greatest multiplicity generally lie lowest, and of these the lowest inta with the greatest L. In Table VI the last listed term is the lowest energy in each family.

Normal States and Electron Configurations of Atoms.—

Normal States and Electron Configurations of Atoms. Quantum principles having thus specified the types of spectral terms arising from certain electrons, it became theoretically possible in 1923 to determine from identified spectral terms the electron configurations of all atoms and their ions. By 1946 the ground states of 8a atom had been uniquely determined from spectral structure, and since had been uniquely determined from spectral structure, and since these data are of great importance in spectroscopy, atomic physics and chemistry, they are collected in Table VII. In addition Table VII lists all the spectral multiphicities experimentally detected, all the reported spectroscopic ionization potentials, and the wave lengths of the strongest spectral lines characteristic of neutral atoms. In general, the strongest lines result from s→p electron transitions.

Hyperfine Structure of Spectral Lines and Properties of Atomic Nuclei.—When examined with apparatus of adequate resolving power, many spectral lines have been found to consist of two or more components lying extremely close together. This hyperness the structure is caused by properties of the stowic nucleus with which

fine structure is caused by properties of the atomic nucleus with which me structure is caused by properties of the atomic nucleus with whene optical electrons interact more or less according to their orbits. The actual line-splitting is exceedingly small (usually a fraction of a wave number) but nevertheless of very great importance because it provides a means of obtaining quantitative information about certain properties of isotopic nuclei. The spectroscopic influence of a nucleus may be due either to its mass or to an intrinsic angular momentum or nuclear spin, analogous to electron spin. The former is called isotope effect and the latter nuclear-spin hyperfine structure, or his for short. (See Plate II, figs. 5, 6, 7, 8.)

Isotope Effect.-Many natural elements consist of a mixture of two or more isotopes, each of which has an approximately whole number atomic weight. Different isotopes of an element have the same number and arrangement of outer electrons, and consequently have the same multiplet structure for their spectra. They are, how-ever, distinguished from each other by their mass because an electron necessarily revolves about the common centre of gravity of itself and the nucleus, and the Rydberg constant therefore depends on the nuclear mass. Thus the Balmer lines of rH<sup>1</sup> atoms are accompanied on the short-wave side by very faint companions ascribed to 1H2 and the detection of these isotope-effect components in 1932 constituted the discovery of heavy hydrogen. Similar isotope effects have been observed in many other spectra, but as soon as several electrons are

present the simple mass effect observed in the hydrogen spectra is complicated by other factors which were not completely understood

in 1947. Nuclear-spin Hyperfine Structure.—True hfs can be simply and quantitatively explained if it is assumed that the nucleus of the emiting atom possesses an angular momentum and an associated magnetic moment. According to quantum theory the nuclear spin can be only an integral or half-integral multiple of  $h/2\pi$ . It is written  $I(h/2\pi)$ , where I is the spin vector or quantum number of the nuclear angular magnetic spin of the spin vector or quantum number of the nuclear angular spin of the spin vector or quantum number of the nuclear angular spin of the spin vector or quantum number of the nuclear angular spin of the spin vector or quantum number of the nuclear angular spin of the spin vector or quantum number of the nuclear angular spin of the spin vector or quantum number of the nuclear angular spin of the spin vector or quantum number of the nuclear angular spin of the spin vector or quantum number of the nuclear angular spin of the spin of t

iar momentum. The spectrum of the  $H_2$  molecule shows that for the simplest atomic nucleus, the proton,  $I=\frac{1}{2}$ . The proton thus has the same mechanical moment as the electron, but various values may be expected for heavier nuclei since they contain more than one proton. As with electron spin, a magnetic moment is associated with the nuclear spin, since the nucleus is electrically charged and the rotation nuclear spiri, since the nucleas is electrically charged and ne foration of electrically charged particles gives rise to a magnetic moment. Because a proton is the same size as an electron but 1,840 times heavier, the magnetic moment of an atomic nucleus is always 1,000 to 2,000 times smaller than that of an electron For this reason the spectral term-splittings (energy differences) deduced from his are usually less

term-splittings (energy differences) deduced from his are usually less than 1/1,000 those in multiplet structure. L and S were combined to obtain the total angular momentum J of the optical electrons, it is necessary, for his, to combine J and I in order to obtain the total angular momentum J of the optical electrons, it is necessary, for his, to combine J and I in order to obtain the total angular momentum F of the whole atom, including nuclear spin. The hyperfine quantum number F can take the following values: F = J + I, J + I - 1, J + I - 2, ..., J - I - I. Thus gives, in all J + I or J + I - I different values, according as J < I or J > I. The vector-addition diagrams for J and I will be identical with those for L and S = I or 
have 2/+1 components.

The magnitude of hyperfine splitting depends on the nuclear magnetic moment but is also dependent on the type of electron. Thus, spectral terms arising from electron configurations containing one spectral terms arising from electron configurations containing one stype electron will be spht wider than those from a p electron with the same principal quantum number, because the s electron approaches closer to the nucleus and experiences a stronger interaction. The transitions between hfs states are regulated by the same selection rule for F that holds for J, i.e.,  $\Delta F = 0, \pm 1$ , but o to o transitions are forbidden. Furthermore, the same intensity rule and the same interval rule is valid for both hfs and ordinary multiplet structure, except F replaces J.

After deriving, from spectroscopic observations and quantum theory, a satisfactory explanation of hfs it became possible conversely to deduce, from the results of spectroscopic experiments, several properties duce, not take teams of spectroscopic expensions, several properties of atomic nuclei. In 13 years following 1927, the mechanical moments or spins of 90 atomic nuclei were determined, the magnetic moments for 70 and the quadrupole moments for 20. The results are compiled in the Journal of the Optical Society of America, No. 36, page 438 (1946). Typical data are shown in Table VIII in which the exponent on the chemical symbol represents the mass of the atomic nucleus. In general, nuclear mechanical moments are derived either from the number of observed his components, or from their relative intensities or from the intervals between his levels. Man witc moments are calculated from a theoretical formula containing the observed his intervals and other constants but the most precise values have been obtained from measured deviations of atomic or molecular beams in tained from measured deviations of aromaco's momenta indicates that the hfs terms are regular, i.e., the level with smallest F value has the lowest energy. Deviations of hfs levels from the interval rule are referred to a quadrupole moment arising from a nonspherical distribu-tion of protons in the nuclei. There are two possibilities: if the pos-litive charge is spread in the direction of the mechanical moment the nucleus is elongated and has a positive quadrupole moment; otherwise the nucleus is flattened and has a negative quadrupole moment.

Table VIII .- Mechanical, Magnetic and Quadrupole Moments of Atomic Nuclei

Mechanical Moment I(h/2π)	Magnetic Moment in Nuclear Magnetons μ(he/.4πMpc)	Quadrupole Moment q(10-24 cm.2)
1/2 1/2 1 1 3/2	-1.035 2.7896 0.855 0.820 3.2532	0.00273
3/2 I 3/2 I	-1.176 0.597 2.682 0.402	
1/2 1/2 3/2 5/2 2/2	2.625 2 215 3.628	
3/2 3/2 3/2 3/2	-1 290 0.217 2 11 2.69	0.20 0.13 -0.4
	Moment $I(h/2\pi)$ 1/2  1/2  1/2  1  3/2  3/2  1	Moment   In Nuclear Magnetons   In Nuclear

The only regularity apparent in Table VIII is that the nuclear mechanical moment is a half-integer if the mass of the nucleus is odd, and a full integer if the mass is even. It is also seen that the algebraic and a ful integer if the mass is even. It is also seen that the algebraic sums of the mechanical moments and of the magnetic moments of the neutron (on!) and proton (IH!) are exactly equal to the respective quantities for the deuteron (1D!). The manner in which the moments of the elementary particles must be combined to yield the observed values for the other atomic nuclei was in 1947 the out-

observed values of the other atomic factor was in 1947 the outstanding and most tantalizing question in nuclear physics.

SPECTROSCOPY, ASTRONOMICAL. Astronomical

SPECTROSCOPY, ASTRONOMICAL. Astronomical spectroscopy is that branch of the science of astrophysics which is built around information obtained by means of a prism, a diffraction grating or some other dispersing device. (See Light; OPTICS.) When a ray of light from the sun is transmitted through a prism it is broken up into its component shades of colour and we observe a continuous spectrum. Closer examination shows that not all shades of colour are represented in the spectrum of sunlight. If the incident light beam is made very narrow by means of a slit which runs parallel to the refracting edge of the prism and if an image of the slit is formed on a screen by means of two lenses; one-the collimator-just in front of the prism, and the other-the camera lens-just behind it, the resulting band of the rainbow colours separates out the radiations so that the missing ones appear as black gaps or absorption lines. The spectra of most stars resemble that of the sun in that they show continuous spectra-some with an excessive intensity in blue light, others with more of the red light-upon which are superposed numerous absorption lines.

Rarely do we observe stellar spectral lines in the form of brilliant emission lines on top of the continuous spectra. The absorption and emission lines are produced by absorbing and radiating atoms in the atmospheres of the stars. Each chemical element or chemical compound has several characteristic sets of spectral lines, and each set is indicative of definite conditions of excitation, such as pressure and temperature. Hence, it is possible not only to identify the chemical elements in the atmospheres of the stars but to draw conclusions concerning the temperature and pressure in these atmospheres,

Some astronomical objects, such as the Orion nebula, produce only emission lines without a continuous spectrum or with one that is abnormally weak. Such spectra resemble those produced by the commercial neon signs used in advertising. Astronomical spectra are of great variety. They represent conditions which range in temperature from a few degrees above the absolute zero for interstellar particles to 100,000° K. (absolute temperature), or even more, in the atmospheres of the hottest star, and 1,000,-000° in the solar corona. In density the range is from that of interstellar space, which contains about 10 atoms per c.c., to that of the atmosphere of a white dwarf (see Stellar Constitution AND EVOLUTION), which exceeds the density of air at the surface of the earth.

Of all the results of stellar spectroscopy the most interesting is the uniformity of distribution of the chemical elements throughout the universe. It must have been a revelation to the earlier spectroscopists when they discovered in the sun the same familiar substances-hydrogen, iron, calcium and the rest-which they knew on the earth. Their belief in the principle of the uniformity of the chemical elements must have been strengthened when several mysterious spectral lines, observed by Norman Lockyer in 1869 at the rim of the sun, turned out, in 1895, to be produced by the newly discovered gas, helium. As recently as in 1941 the last great enigma of line-identification was solved when B. Edlén in Sweden announced that the previously unidentified lines of the solar corona originate in the atoms of the common elements, iron, calceum, nickel and argon, excited to a degree of ionization not even dreamed of previously. Henry Norris Russell had remarked some years earlier, when Ira S. Bowen in a similar manner disposed of the so-called "nebulium" lines in certain nebulae, that the mysterious substances of the astrophysicists one after another literally disappeared in "thin air." As a matter of fact. Bowen found that the nebulae consist of oxygen, nitrogen, hydrogen and a few other gases, in other words, they are not very different in composition from air The principle of the uniformity of chemical elements has now been extended to include even the distant galaxies whose light travels hundreds of millions of years at the rate of 186,000 mi. per sec before it reaches the eye of the observer. The principle of uniformity of chemical elements means that the atomic building blocks of the universe are the same throughout space. It does not mean that the proportions of these elements are the same in all astronomical objects.

### HISTORICAL DEVELOPMENT

Astronomical spectroscopy had its beginning in 1666 when Isaac Newton observed the separation of the colours of the rainbow in a prism. In 1802 William H. Wollaston placed a narrow slit in a window blind and with a prism of better quality than the one used by Newton, but without a collimator or a camera. noticed several dark lines in the spectrum of sunlight. Real progress in astronomical spectroscopy became possible when Joseph von Fraunhofer in 1814 made use of a telescope, in addition to the prism and a distant slit, and thereby constructed the first modern spectroscope. A collimator lens was first used by W. H. Simms in 1840. With his instrument Fraunhofer observed and mapped 754 dark lines in the spectrum of the sun. He also observed the spectra of several bright stars and found that although they all had dark lines upon a coloured continuum, the lines were not the same as those of sunlight. Fraunhofer noticed that the vellow emission line from a flame fed with table salt, which had already been observed by John Herschel, coincides in position with a conspicuous black line in the solar spectrum, which he had designated by the letter D. But he did not follow up this result.

It was only after Gustav R. Kirchhoff had advanced his famous three laws of spectroscopy that the connection between absorption and emission became obvious. Thereafter William Huggins (1824-1910) in England undertook a systematic survey of the spectra of all stars and nebulae within the reach of his instruments at Tulse Hill in London. This period was the richest in the number and importance of astrophysical discoveries. Many different types of stellar spectra were found; the Orion nebula was found to be gaseous, contrary to the opinion of other astronomers, while the Andromeda nebula showed a continuous spectrum similar to that of normal stars like the sun. Huggins concluded independently of Johann K. F. Zöllner that the solar prominences could be observed without an eclipse by means of a spectroscope, and that the planets shine by reflected sunlight. He was the first to try to measure the radial motions of stars from the Doppler displacements of their lines. The work of Huggins was of a pioneering character, and it was he who laid the foundations for all further investigations. His tradition in England was carried on by Norman Lockyer and F. E. Baxandall at the Solar Physics observatory in South Kensington, which was transferred to Cambridge after Lockyer's retirement in 1913, and was directed first by H. F. Newall and later by F. J. M.

The problem of spectral classification was undertaken in the middle of the 19th century b, Angelo Secchi in Italy and was later continued by H. C. Vogel in Germany who was the first to introduce the photographic method into spectroscopy and who succeeded in determining accurate radial velocities of many stars. Vogel's work, especially his measurements of radial velocities, stimulated several other observatories, near the turn of the century, to undertake systematic studies in this field. W. W. Campbell at the Lick observatory undertook the determination

of the motions of all stars brighter than magnitude 5.5 in both hemispheres of the sky. E. B. Frost at the Yerkes observatory concentrated upon the motions of hot stars. J. S. Plaskett at Victoria, British Columbia, discovered many spectroscopic double stars and determined their orbits; he also extended to fainter stars the work of other observatories. W. S. Adams and his associates at Mount Wilson observatory, Calif., determined the velocities of hundreds of faint stars. A. A. Belopolsky at Pulkovo, Russia, and, more recently, G. A. Shajn at Simeis, in the Crimea, also made important contributions in this field. H. Spencer Jones, then at the Cape observatory, published numerous measures of stellar motions in the southern sky.

The work on spectral classification received a new impetus when E. C. Pickering at Harvard, assisted by Miss A. J. Cannon, Miss A. C. Maury and Mrs W. P. Fleming, undertook the classification of several hundred thousand stars over the entire sky. This work, which culminated in the Henry Draper Catalogue by Miss Cannon, published 1918-24, provides the basis for all modern astrophysical work. The spectroscopic study of the sun was advanced by J. C. Janssen, of the Meudon observatory in Paris, who followed Huggins' suggestion and succceded, in 1868, in observing the prominences of the sun in full daylight. Further advances were made by N. C. Dunér in Sweden, who determined the rotation of the sun from the Doppler effect (q.v.) and found it to be different in different latitudes of the sun, and by H. A. Rowland at Johns Hopkins university, who prepared a catalogue of solar wave lengths. At the turn of the century great progress in this field was made by G. E. Hale, who successively founded and directed the Kenwood observatory in Chicago, the Yerkes observatory in Williams Bay, Wis., and the Mount Wilson observatory at Pasadena, Calif. The spectroheliograph was invented independently by Hale and Deslandres of the Paris observatory. Hale discovered the magnetic fields in sunspots and announced the existence of a 22-year period in the polarity of sunspots. One of his most striking discoveries was that of invisible sunspots, made in 1922; he pointed out that sunspots usually appear in pairs of opposite magnetic polarity. He concluded that single spots are single only in appearance, and that in all probability they are associated with invisible spots "in which the cooling due to expansion is insufficient to cause perceptible darkening of the sun's surface." He was able to confirm this hypothesis by means of the Zeeman effect (q.v.)which clearly demonstrated the existence of the invisible spots of opposite polarity to that of the visible single spots.

The connection between the temperature of the stars and their colours was recognized as soon as differences in colour were observed, but the reddening effect of interstellar dust was for many years a subject of controversy and was settled only through the work of R. Trumpler at the Lick observatory. The recognition of spectroscopic differences between stars of high and oi low luminosity goes back to the work of E. Hertzsprung, around 1905, but the systematic utilization of the method of spectroscopic parallaxes—the most powerful means of penetrating distance within our galaxy—was developed by W. S. Adams and A. Kohlschütter at the beginning of World War I.

## INSTRUMENTS

Silt Spectrograph.—The stellar spectrograph is an instrument constructed like an ordinary laboratory spectrograph (see Spectroscoper: Spectroscopes and Spectrograph(see Spectroscoper). Spectroscopes and Spectrograph(see Department) all astronomical light sources are exceedingly faint, special precautions must be observed that all the available light of the object be utilized in forming the spectrum The instrument most commonly used is a slit spectrograph attached at the focus of an astronomical telescope. It is essential that the angular aperture of the collimator be the same as that of the telescope. Otherwise, light is spilled over the edges of the collimator (collimator of greater focal ratio than telescope) or the optical parts of the spectrograph are unnecessarily large and wasteful (collimator of smaller focal ratio than telescope). If the instrument is used in good seeing for the observation of stars, which appear nearly as points on the slit of the spectrograph, then the efficiency is pro-

proportional to the length of the collimator. But if the instrument is used for the observation of luminous surfaces, such as nebulae, the moon, the planets, etc , the efficiency is independent of the linear or angular apertures of the telescope and depends only upon the aperture of the collimator.

In practice the astronomer is usually concerned with intermediate conditions; the stars have tremor disks caused by irregularities in the air, and while their images have a pronounced, sharp peak of light intensity in their contours, they cannot be regarded as mathematical points. Hence, it is advantageous to use a telescope of large aperture to gather in a large amount of light, and a long collimator to secure the maximum possible purity. In very "poor seeing," when the star images may be as large as 1 minute of arc in diameter (this would project as a disk of 4 mm in diameter on the slit of the spectrograph of the 82-inch reflector of the McDonald observatory) the advantages of the large aperture are largely lost, while in good seeing, when the diameter of the image is less than one second of arc, the efficiency is almost exactly proportional to the linear

The length of the camera and the dispersion of the prism or grating are chosen to give the desired scale of the spectrum. For very bright objects long cameras and powerful dispersing units may be used. For example, the spectrum of the sun has been completely photographed for photometric purposes in the first and second orders of a diffraction grating having 600 lines per millimetre and installed in a 75-foot spectrograph of a 150 ft. tower telescope at the Mount Wilson observatory. The linear dispersions of these plates were 0.33 Å/mm. and 0.67 Å/mm. For special purposes even higher dispersions can be used to advantage. For the brightest of the fixed stars, linear dispersions of one A/mm, have been used at Mount Wilson. Naked-eve stars have been photographed with 2 to 3 Å, mm. The ordinary stellar spectrograph used for radial velocity work (see later) has a dispersion of the order of 10 to 75 A/mm. Finally, for the faintest objects, such as stars of apparent magnitude 16, or fainter for galactic nebulae, external galaxies, etc., dispersions of 500 to 1,000 A/mm. are frequently used.

The design and construction of spectrograph camera systems constitutes one of the most difficult tasks in optics. For the greatest efficiency it is desirable to make the ratio of collimator to camera lengths as large as possible, so that the slit can be opened without increasing the width of the projected image of the slit on the plate to more than the size of the plate-grain clusters. Thus, short-focus cameras are favoured, which require dispersing units of great power in order to secure the desired scale of the spectrum. For ordinary work with cameras of the order of f/3 to f/5, four-component lenses designed by F. E. Ross or three-component Cooke-type lenses give excellent results. For instruments of very short focus, Schmidt cameras of conventional design can be used down to about f/1; modified Schmidt cameras made from a solid block of glass, one side of which is figured to approximate a sphere and silvered on the outside while the other side is figured in such a way as to remove the spherical aberration, can be used at a speed of f/0.35. Schmidt cameras of improved design have been proposed by James Baker at Harvard. Microscope objectives for use as camera lenses were proposed by W. B. Rayton and by R. J. Bracey. A lens designed by the latter at f/0.35 has been used successfully at the Mount Wilson observatory for work on external galaxies.

Slit spectrographs are usually attached at the focus of a moving telescope and must meet two important requirements: they must be sufficiently rigid to show no perceptible change in flexure during a long exposure and they must be accurately controlled for temperature to prevent changes in excess of about o.r° in the spectrograph throughout the night. Permanent stationary spectrographs of high dispersion are used for solar work where vertical towers with mirror systems (coelostats) are used for forming the solar image on the slit, and a vertical underground shaft serves to house the spectrograph. Installations of this type are used at the Mount Wilson observatory, Pasadena,

portional to the area of the telescope objective while the purity is Calif., at the McMath observatory of the University of Michigan at Pontiac, Mich, at the Potsdam observatory in Germany, at the Arcetri observatory near Florence, Italy, and elsewhere For stellar work stationary spectrographs are used at the Coude focus of very large reflecting telescopes. The Mount Wilson observatory and the McDonald observatory of the University of Texas, Fort Davis, Tex, have made excellent use of such installations.

The principal advantages of sht spectrographs consist of (1) greater purity than is possible with slitless instruments, (2) a comparison spectrum that can be photographed alongside the astronomical spectrum to serve in radial-velocity determinations and (3) the elimination of the background of the night sky, which places a definite limit to the efficiency of slitless instruments. The spectral region covered with modern instruments ranges from \$\lambda\$ 2900 \, A, where the terrestrial atmosphere becomes opaque, to about \(\lambda\) r3.500 \(\lambda\), where even the special infra-red photographic emulsions cease to be effective. In fact, for stellar work the practical photographic limit in 1945 was about λ 10,000. Beyond this limit special methods may be used, such as employing thin layers of a substance which vaporizes easily and is removed from regions exposed to infra-red radiation, being deposited on the cooler, unexposed regions. In 1946, two sensational advances were made in extending the observable spectral region; physicists of the U.S. Naval Research laboratory at Washington, DC., announced that with a spectrograph in a German V-2 rocket at White Sands, N.M., they had photographed the sun's radiation to about \( \lambda \) 2,100 at a height of 33.5 mi. In the infra-red region the construction of special PbS photoelectric cells by R. J. Cashman permitted G. P. Kuiper and W. Wilson to observe the spectra of stars and planets to about 3 µ, with sufficient dispersion to record a mass of new absorption features.

The dispersing units of astronomical spectrographs are made in the form of prisms (glass, quartz, rock salt) or of diffraction gratings. The latter are particularly useful in the red and infrared regions, where the dispersion of glass is so low that a prohibitive thickness of the substance is required to obtain the same dispersion that a grating with 600 lines per mm. gives in the second order. The grating is also efficient in the ultra-violet region, where ordinary glass is opaque and where quartz prisms are difficult to obtain in sufficiently large sizes for high-dispersion instruments. Large quartz prisms of the Cornu type are used at the McDonald observatory. R. W. Wood at the Johns Hopkins university ruled gratings on a thin aluminum film deposited on glass, using diamonds specially shaped to give the highest possible concentration of light in the desired region of the spectrum. Other fine gratings have been ruled at the Mount Wilson observatory. Unusual freedom from "ghosts" has been achieved in the ruling engine at the University of Chicago.

Under ordinary observing conditions a large amount of light is lost on the slit jaws of the spectrograph (where it is used for guiding the telescope on the star image). It is not possible to filter this light into the spectrograph in such a way that it will reinforce the spectrum of the central portions of the star image. But an ingenious device has been constructed by Ira S. Bowenan instrument called the image slicer-in which small plane mirrors are used to place the originally wasted light in the slit, alongside the main spectrum.

In this manner a widened spectrum is obtained without letting the star trail on the slit, and this results in a substantial reduction of the observing time.

Very large luminous areas, such as diffuse gaseous nebulac, the zodiacal light, etc., can be observed without a telescope if the collimator is sufficiently long so that its angular aperture is smaller than the diameter of the object. A powerful spectrograph employing a slit of 2 to 3 cm. in width and 1 m. in length, at a distance of 46 m. from two quartz prisms, and a f/1 Schmidt camera of 94 mm. aperture, was used at the McDonald observatory for recording the spectra of exceedingly faint nebulous regions in the Milky Way. This instrument has no collimator lens because the rays are sufficiently nearly parallel when they enter the prism.

Slitless Spectrographs.—The image of a star is approxi-

mately a point. Hence, if a prism is placed in front of the lens or mirror of a telescope, the spectrum is recorded as a narrow continuous band with interruptions in place of spectral lines. If during the exposure the star is permitted to trail slightly in a direction parallel to the refracting edge of the prism, a widened spectrum is obtained in which the star serves as its own slit. The great advantage of slitless spectrographs consists in the fact that they record a large field of stars in a single exposure instead of being limited to a single star on the slit of the instrument. The principal disadvantage lies in the fact that in a large telescope, such as would be required to record the spectra of very faint stars, the images of the stars are tremor disks of appreciable diameter, the latter being very sensitive to the conditions of seeing in the atmosphere.

Hence, spectra obtained in this way are not as pure as are spectra obtained with slit spectrographs. Another difficulty consists in the absence of a comparison spectrum for determining the radial motions of the stars. This can be circumvented by placing a glass container of a solution of neodymium chloride in the path of the rays. This substance produces one sharp absorption band in the photographic region, which can serve as a reference point for measuring the displacements of the stellar lines. Nearly all work on the spectral classification of faint stars is being carried on with objective prisms.

Various modifications of the objective prism have been invented for special purposes. The light rays can be made parallel by means of a negative lens just before they reach the focus of the telescope and a prism or grating can be used to produce slitless spectra of stars and small nebulae, which are then brought to a focus by means of a positive lens. Instruments of this kind are being used in several observatories, one of the most successful being the slitless spectrograph of the 36-inch Crossley reflector of the Lick observatory, with which W. H. Wright obtained some of the finest spectra of small planetary nebulae.

The wide field and the critical definition of star-images at relatively short focal lengths, obtained with large Schmidt cameras, render these instruments especially suitable for objective-prism work Among the best instruments of this type are the 24-inch Schmidt reflector of the Case School of Applied Science in Cleveland, O., and the 18-inch telescope on Mount Palomar in California

Among the many slitless spectrographs one designed by E. L. McCarthy for the McDonald observatory deserves special menton. A prism with a small silvered spot on one face is placed near the principal focus of the large reflector. The rays reflected from the spot are collimated by a small parabolic mirror whose coma cancels that of the large telescope. The collimated beam passes through the prism and is focused by means of an f/2 Schmidt camera. The entire instrument works at f/2 and the star images are made reasonably small by the reduction from f/4 of the large telescope. Another interesting arrangement was used by W. M. H. Greaves and others at the Greenwich observatory. In this instrument the beam is collimated by the secondary Cassegrain mirror before it enters the prism.

Spectrophotometric Instruments.—For the measurement of the light intensities in continuous spectra and in spectral lines microphotometers of various designs are used. Usually the instrument is employed to measure the photographic density on a plate, but occasionally direct measures of the light at the telescope are preferable. Instruments for measuring photographs usually consist of a light-source and a narrow slit; the latter—or its image—is placed in contact with the plate, parallel to the spectral lines, so that only a narrow band of light passes through the plate. This band falls upon a photoelectric cell which activates a galvanometer whose mirror produces a displaced light signal upon a sheet of photographic paper. As the plate is slowly moved across the slit, the drum carrying the paper is turned and the signal produces a continuous record of the galvanometer deflection of the original beam as modified by the continuous spectrum and by the lines on the plate. Tracings of spectra obtained in this manner must be calibrated by means of

marks produced on the original plate by a step wedge, a tube sensitometer or some similar device which changes intensities by known amounts. This is required in order to express the displacements of the signal on the tracings in terms of relative intensities.

Since this conversion is often laborious, a number of devices have been perfected for reading directly the intensities on the tracing, or for converting the original tracing automatically into one giving relative intensities. Instruments of this type have been used by R. C. Williams and W. A. Hiltner at the University of Michigan, by M. Minnaert and his associates at Utrecht, by Theodore Dunham, Jr. at Mount Wilson and elsewhere. Dispersing systems have been used by J Stebbins and A. E. Whitford at Mount Wilson and by J. Hall at Amherst to serve for the photoelectric measurement of approximately monochromatic star images.

The Spectroheliograph was invented almost simultaneously. in 1890 by G. E. Hale in Chicago and by H. Deslandres in Paris. This is a large spectrograph into which a narrow slit has been built in front of the focal plane of the camera so that only the light of a narrow range of wave lengths falls upon the plate. This slit is so adjusted that the light of a particular absorption line in the sun's spectrum is transmitted. It must be remembered that the lines originate in the uppermost regions of the sun's atmosphere and are not completely dark but contain light of smaller intensity than that of the continuous spectrum. The continuous spectrum is formed by light which is produced, on the average, at a depth of several hundred kilometres in the atmosphere. The image of the sun is projected upon the first, the ordinary, slit of the spectrograph and the entire telescope is slowly moved by means of an electric motor at right angles to the slit. Simultaneously the plateholder carrying the sensitive emulsion is moved past the second slit. In this manner an image of the sun is obtained on the plate which is produced by the residual light of a particular spectral line. Since not all regions on the surface of the sun are equally bright in such monochromatic light, it is possible to study features like calcium eruptions (or flocculi), hydrogen tornados (or vortices) and other structures which cannot be seen in the brilliant light of the continuous spectrum which alone is strong enough to register in the extremely short exposures required for obtaining a direct photograph.

A modification of the spectroheliograph, the spectrohelioscope, was invented by Hale for visual observation. Some phenomena, such as brilliant eruptions in hydrogen light (bombs), last only a few minutes and can best be detected and followed by means of prolonged visual observation.

R. R. McMath of the University of Michigan has improved the spectroheliograph by combining it with a moving picture machine so that a continuous record of a solar phenomenon may be obtained. Since radial motions in the solar atmosphere sometimes shift a spectral line outside the limits of the second slit, a picture obtained in two dimensions is necessarily distorted and is inadequate for many purposes. To correct this feature, McMath has built an instrument referred to as a radial-velocity-spectroheliograph, which resembles an earlier instrument by Deslandres. By its means it is possible to study the radial motions, as well as the tangential motions, of such features as prominences, eruptions, etc.

Coronal Spectrographs.—B. Lyot built on the Pic du Midi in France an instrument with which he succeeded in photographing the spectrum of the solar corona on any clear day. The principal new feature of this instrument consisted of devices for the elimination of scattered light in the optical parts. All glass parts were chosen for freedom from bubbles and striae and the surfaces were made and are kept free from scratches, minor irregularities and dust. In addition, the direct image of the sun was eliminated by an occulting disk, and special precautions were taken to eliminate diffracted light from the image forming lens. Other coronal spectrographs are used at Arosa in Switzerland by M. Waldmeier and at the Climax station of the Harvard observatory by D. H. Menzel and W. O. Roberts.

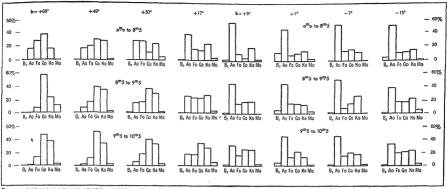

FIG 1 -THE DISTRIBUTION OF THE RELATIVE NUMBERS OF STARS OF DIFFERENT SPECTRAL CLASSES. THE SYMBOL & INDICATES THE GALACTIC LATITUDE

# CLASSIFICATION OF STELLAR SPECTRA

Methods.—Nearly all of the 500,000, or more, stellar spectra which have been examined at several observatories can be arranged empirically in a two-dimensional sequence in which the intensities of selected absorption lines or bands change gradually. The system of classification of stellar spectra is based principally upon the Henry Draper Catalogue of the Harvard observatory where spectral types of nearly 300,000 stars are given. This work recognizes only one dimension or parameter in the classification, which has since been identified as the temperature of the atmosphere of the star. In this one-dimensional system two stars may have identical intensities of some lines, and slightly different intensities of others. Most of these discrepancies were removed when it was recognized that stars of different luminosity, but of similar temperature, show slightly different spectra.

The temperature co-ordinate can be empirically divided into a number of steps which are designated, following Miss Cannon's procedure, by the letters O, B, A, F, G, K, M, R, N and S, or by actual temperatures, which for the sequence named decrease steadily from about 30,000° K. for type O, to about 3,000° K. for types M, R, N and S. Since the exact correspondence between temperature and empirical spectral class is not known, the empirical scheme is used for most purposes. The second co-ordinate can also be expressed by arbitrary designations such as I, II, III, IV and V, used by Morgan and Keenan at the Yerkes observatory, or by actual luminosities expressed in the form of absolute stellar magnitudes, which the stars would have if they were brought to a distance of 10 parsecs, or 3 x 1014 km. Stars of luminosity class I have absolute magnitudes of the order of -5, those of class V of the order of +5. The latter value corresponds to about the intrinsic brightness of the sun, while the former would be 10,000 times brighter. In this case, again, the use of arbitrary designations is preferable as long as we do not have an accurate calibration in terms of absolute magnitudes.

The hottest stars, class O, have spectra dominated by the lines of ionized helium; those of class B have hydrogen and neutral helium. In class A hydrogen is very strong, helium is weak or absent, and ionized metals, such as Fe II, Ti II, Mg II, are prominent. In types F, G and K the lines of neutral metals, Fe I, Ti I, etc., become gradually stronger, and the lines of Ca II, Ca I and Na I are conspicuous. Near type G we first observe bands of certain diatomic molecules, CH and CN, which also increase in strength as we pass toward the cooler stars. Types M, R, N and S are characterized by very strong molecular bands of TiO in class M, C2 and CN in classes R and N and ZrO in class S. These four types do not form a well-defined

temperature sequence, and the exact interpretation of the empirical classes in terms of physical parameters is incomplete.

The luminosity criteria which are used within each spectral class differ greatly. In the hottest stars, classes O, B and A, the hydrogen lines are much narrower in the more luminous stars (supergiants). In the intermediate and cool stars, lines of relatively high ionization potential, such as Sr II in classes G and K, are enhanced in the more luminous stars. The molecular bands of CN, and others, can also be used as luminosity criteria.

An accurate classification of stellar spectra is important for three widely different problems: (1) the study of the physical properties of stellar atmospheres, (2) the statistical study of stars according to their principal characteristics and (3) the study of the spatial arrangement of the stars in our galaxy by means of their luminosities. It is important to have a clear understanding of the purpose of an investigation before the methods and the criteria are chosen. Thus, certain spectral features may be useful in empirical determinations of luminosities, but may be almost useless in studies of physical characteristics because they consist of unresolved lines or bands of different sources.

The principal catalogues of stellar spectra are those of the Harvard observatory—the Henry Draper Catalogue, which covers the entire sky and is complete to about apparent magnitude 8.5, and its extensions, which carry the work to much fainter stars in selected regions of the sky. Approximately 100,000 faint stars located in the selected areas of the southern sky, chosen by J. C. Kapteyn, were classified by F. Becker and H. Brück at the Potsdam observatory from photographs taken at La Paz, Bolivia. A similar study for some of the northern selected areas, containing approximately 68,000 stars to apparent magnitude 13, was made by A. Schwassmann at the Bergedorf observatory near Hamburg. Spectral types of several thousand other stars located in regions of special interest, such as star clusters, nebulae, Milky Way clouds, etc., have been determined by A. A. Wachmann at Bergedorf, by numerous observers at the observatories of Upsala and Stockholm in Sweden and elsewhere.

In most of these studies only the temperature parameter of the classification has been recognized. At the Dearborn observatory O. J. Lee has made a search for stars of very low temperature over the northern sky. At the McCormick observatory of the University of Virginia, Charlottesville, Va., A. N. Vyssotsky was engaged in 1945 in a systematic classification of about 500,000 stars in 1,200 areas of the sky to magnitude 12. Classifications of several hundred faint stars have been obtained with slit spectrographs by M. H. Humason at Mount Wilson and by W. W. Morgan at the Yerkes observatory.

The percentage distribution of the stars according to spectral type is shown in fig. x taken from the Bergedorf catalogue. The stars are divided into several groups according to their galactic

latitude (angular distance from the central line of the Milky Way) and apparent magnitude. The hotter stars have a pronounced tendency to concentrate near the Milky Way, while the

cooler stars are more evenly distributed.

Interpretation of Spectral Classification.-The theoretical interpretation of the two-dimensional classification of stellar spectra rests upon the theory of thermal ionization proposed by M. N. Saha in 1920 and developed in later years by H. N. Russell, E. A. Milne, R. H. Fowler and others. Some of the ideas underlying this theory were already present in the pioneering work of Norman Lockyer, but the exact mathematical formulation was first given by Saha. In a gas submitted to high-temperature radiation neutral atoms are constantly being ionized by quanta of light, and free electrons are being captured by ions. An equilibrium is set up by which the number of ionization processes is exactly balanced by an equal number of recombinations. The relative numbers of ions (n') and neutral atoms (n)depend upon the temperature of the radiation (T), the ionization potential of the atoms (I), and the partial pressure  $(p_e)$  of the free electrons, many of which may result from the ionization of some other element than the one we are considering:

$$\log_{10} \frac{n'}{n} = -I \frac{5040}{T} + \frac{5}{2} \log_{10} T - 0.48 - \log p_e$$

The observed intensity of a neutral line is directly dependent upon  $n_t$ , that of an ionized line upon n'. As the temperature increases,  $n_t$  decreases while n' increases, by virtue of the first factor containing  $T_t$ , which is more important than the second factor. The ionization is smaller when I is large. But the ratio n'/n also depends upon  $p_0$  and increases as the pressure decreases.

Consider two stars of the same temperature but of different pressures and suppose that we observe in their spectra lines of two elements having different ionization potentials. In the dense star the ionization is less than in the more tenuous star. Moreover, the element of higher potential will be less ionized than the one of lower potential. In practice we do not choose the stars according to temperature but according to spectral class. The latter rests upon a compromise of several slightly conflicting criteria, corresponding to different ionization potentials; for example, two stars classified as F do not have exactly the same temperature if their pressures are not alike; the more tenuous star has the lower temperature. It must also be remembered that many elements can be ionized more than once, so that as T increases or pe decreases, n' at first increases at the expense of n, reaching a maximum at definite pairs of values of T and pe, after which it again decreases, while n', representing the next stage of ionization, begins to increase. Ionization temperatures are determined for a sequence of stars for which it may be assumed that  $p_0$  is constant, by observing at which spectral class lines of different ionization potential reach their greatest intensity. The condition for maximum intensity is obtained by differentiating the ionization formula with respect to T.

The theory of ionization suffices to explain many of the observed absolute magnitude effects in stellar spectra, remembering that for a given temperature high luminosity is equivalent to large size (giants) and therefore to small surface gravity and, in turn, small surface gravity indicates low pressure. The tendency of ionized lines to become stronger in giants is explained by the fundamental formula. But other effects require a more complete theory which has been developed by Milne and which involves the interplay of two tendencies: (a) the increased effective mass of the atmospheres of giants as compared with dwarfs, and (b) the effect of altered pressure, consequent on change in surface gravity, on ionization.

change in surface gravity, on ionization.

Continuous Spectra.—The continuous spectra of the stars show conspicuous differences in the distribution of energy as a function of wave length. The latter are closely related to the observed colours of the stars. The O and B stars are bluish, while the M, N, R and S stars are red. Observations of the absolute energy distributions of selected stars have been made by Vogel, G. Müller and others at Potsdam, by Greaves and his associates at Greenwich, by R. C. Williams at the University of Michigan,

by D. Chalonge and D. Barbier in France, and by others. From these observations the absolute colour-temperatures are derived by adjusting T in the Planck function (see Hear) to give the best possible fit with the observed distribution. These absolute determinations have yielded a number of standards with which it is possible to compare other stars. Differences in the energy distributions of two stars are usually given in the form of "relative gradients":

$$\Delta \phi = \frac{c_2}{T_1} - \frac{c_2}{T_2},$$

where  $c_7$  is the constant of the Planck function. These considerations rest upon the empirical fact that the energy distributions of many stars, in regions not affected by absorption lines, resemble fairly closely the black-body curves. However, accurate observations have shown a number of important departures:

(1) At the limit of the Balmer series the spectra of moderately hot stars (class A) show a discontinuity, usually described as the "Balmer jump": the continuous spectrum is abnormally weak on the violet side of \(\lambda\) 3647. (2) In the spaces between the strong hydrogen absorption lines on the violet side of H y of many A-type stars the continuous spectrum is depressed because of the enormous extent of the wings of these lines, this phenomenon being especially conspicuous in white dwarfs, like O2 Eridani B. (3) In some stars the hydrogen lines are complicated by emission, and the "Balmer jump" appears as an abnormal strengthening of the spectrum on the violet side of \( \lambda \) 3647 (4) In a few unusual stars the colour temperature is different for In a few unusual stars the spectrum: for example, in P Cygni, J. Dufay found colour temperatures of the order of  $6,000^{\circ}$  to  $7,000^{\circ}$  in the region of  $\lambda$  5,000 Å, with a tendency to increase in the shorter wave lengths. The spectral type suggests that the temperature is about  $18,000^{\circ}$  in the region  $\lambda$  500 to  $\lambda$  1000 Å, but this depends upon an indirect conclusion. (5) Many distant stars appear greatly reddened by selective absorption in interstellar clouds. This type of reddening is not in accordance with Rayleigh's  $\lambda^{-1}$  law but is more nearly proportional to  $\lambda^{1}$ . (6) In stars which have heavy absorption lines and molecular bands, there must be a pronounced distortion of the continuous spectrum because of the "blanketing effect" of the absorption features. This phenomenon has been predicted theoretically by S. Chandrasekhar and observed indirectly in the central intensities of He absorption lines by A. Unsöld. (7) The continuous spectrum of the sun is weaker and redder at the edge than in the centre, and the combined light is therefore a mixture of different energy distributions. This phenomenon of limb darkening is present also in a number of eclipsing variables. (8) A strange inconsistency between spectral class inferred from the absorption lines and colour temperature inferred from the surface brightness is observed in several close double stars. This effect is attributed to the "reflection effect" which causes lines of relatively high excitation to be produced in the atmosphere of a cool binary component by the radiation of a hot component.

All of these phenomena are reasonably well understood. The theory of the continuous spectrum, and especially of the effect of limb darkening, is closely related to the problem of the physical mechanism which causes the gases in the outer layers of stars to be more or less opaque to continuous radiation. Continuous absorption at the series limits of H and He, and to a lesser extent of other elements, scattering of light by free electrons, and, in the cooler stars, continuous absorption from negative ions of hydrogen and probably of other elements are known to contribute to the continuous absorption coefficient (as distinct from the absorption coefficient within a spectral line). The energy distributions of the stars in the extreme ultra-violet region are not observed because of the oxygen and ozone bands in the upper air. Considering the very high absorption of H at the Lyman limit and the probable strength of the Lyman absorption lines, this energy curve must depart greatly from that of a black body. There is some evidence that there may even be a tre-mendous excess of ultra-violet light in the sun, which would

account for the presence of He II in the chromosphere, but this is not certain.

### RADIAL VELOCITIES

The Doppler principle gives the displacement of a spectral line  $(\Delta\lambda)$  as a function of the wave length  $(\lambda)$  and the relative radial velocity of the source and the observer (v):

$$\Delta \lambda = \frac{\lambda \cdot v}{c}$$
,

where c is the velocity of light. The displacement can be measured on plates furnished with a comparison spectrum and, accordingly, v can be determined. The quantity thus obtained must be corrected for the components of the earth's motion around the sun and the earth's rotation around its axis. The precision of the determination depends upon the dispersion of the spectfogram, the precision of the laboratory wave lengths used for star and comparison lines, the sharpness of the star lines, the quality of the optical parts used, the uniformity of the illumination of the slat and the collimator by the star image and a number of other factors. W. W. Campbell and J. H. Moore at the Lick observatory obtained a precision of about o.t km/sec. for the best stars photographed on many nights. They investigated all systematic errors and established an accurate system of radial velocities free of any appreciable systematic errors.

With the highest attainable dispersion of the Mount Wilson Coudé spectrograph, Adams obtained the velocity of  $\alpha$  Bootis with a probable error of  $\pm$ 0  $\pm$ 0  $\pm$ 0 km/sec. The largest velocity of a single star in our galaxy is more than 500 km/sec. The average velocity of the stars is of the order of 10 to 15 km/sec. It varies with spectral class; the B stars have smaller individual motions than the stars of lower temperature. The most complete catalogue of radial velocities is by Moore and was published in 1932 as volume 18 of the Publications of the Lick Observatory. It contains 6,739 stars, 133 gaseous nebulae, 18 globular clusters and 90 extragalactic nebulae. However, many new velocities have been obtained since 1932, especially by M. H. Humason for extragalactic nebulae and by N. U. Mayall for globular clusters.

Among the results obtained with the aid of radial velocities are the following: (1) The determination of the velocity (about 20 km./sec.) and the direction in space of the motion of the solar system, with respect to the nearer stars. (2) The recognition that the entire galaxy rotates around a distant centre located in the direction of the constellation Sagittarius, with a velocity of between 200 and 300 km./sec. in the region where the sun is located. (3) A method for determining the distances of groups of stars from the effect of galactic rotation, because the differential motion is directly proportional to the distance. (4) The discovery of the so-called K-effect, which can be described as a slow expansion (about 4 km./sec.) of the system of relatively near stars of spectral class B but which has not been adequately explained; it may be caused by the accidental distribution of the motions of only a small fraction of the stars. (5) The discovery that all rapid stars tend to be moving in the same direction with respect to the sun; this phenomenon can be satisfactorily explained in terms of the theory of galactic rotation if it is remembered that the orbits of individual stars may be highly eccentric, instead of circular. (6) The measurement of red shifts (inferred from the existence of otherwise unaccountably large recessional velocities) amounting to about 20 km./sec. in very dense and massive stars, such as the white-dwarf companion of Sirius, the hot Trumpler stars in clusters and the group of O stars in the Orion nebula; it is possible that these red shifts are caused by the Einstein effect (see GRAVITATION). (7) The existence of a peculiar connection between the average speed of a group of stars and certain peculiarities in their spectra; for example, all so-called sub-dwarf stars (less luminous than real dwarfs) have fast motions. (8) The law of linear increase in the velocity of recession of external galaxies with distance; the largest velocity known in 1945 was about 20,000 km./sec. (9) The determination of the distance of the sun from measurements, throughout the entire year, of the relative velocity, with respect

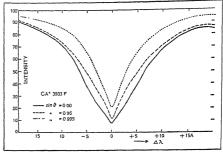

FIG. 2.—PROFILES OF THE STRONG LINE CA II K IN THE SPECTRUM OF THE SUN:

(----) near the centre of the sun's disk; (---) at a point intermediate between centre and limb, (...) near the extreme edge of the sun. These profiles are breadened by the effects of radiation damping and collisional damping. The general weakening of the line from centre to limb is explained by the theory of transfer of radiation through a stellar atmosphere

to the earth, of a star of constant radial velocity; in this problem, worked out by H. Spencer Jones at the Cape of Good Hopeobservatory and by W. S. Adams at Mount Wilson, the variable correction of the star's velocity to the sun is regarded as the unknown, and the distance appears through its connection with the orbital velocity of the earth. (10) The discovery of numerous stars showing periodic variations in radial velocity—close double stars, pulsating stars, etc. (11) The study of eruptions in novae and in other expanding shells of gas which surround such stars as P Cygni and others. (12) The discovery of stationary lines in spectroscopic binaries and their interpretation as absorption produced by interstellar gas.

# ASTROPHYSICAL RESULTS OF ASTRONOMICAL SPECTROSCOPY

Although the great majority of the stars can be arranged within the two-dimensional framework of the temperature-luminosity classification there are some important exceptions

The Wolf-Rayet Stars, numbering less than 100 out of about 500,000 well-observed stars, show continuous spectra upon which are superposed broad emission bands of atoms of a high degree of ionization, such as He II, C III, C IV, N III, N IV, N V, etc. These bands are often flanked on their violet sides by more or less diffuse absorption lines-a phenomenon which is believed to indicate that the lines and bands originate in shells expanding in all directions with velocities of several hundreds or even several thousands of km./sec. No forbidden lines have been found among the various features, which suggests that the shells cannot be very great in extent. A large fraction of the known Wolf-Rayet stars are close binaries, and in some the spectra of the companions turn out to be normal stars of class B. In these cases the Wolf-Rayet stars invariably have much smaller masses. O. C. Wilson, working at Mount Wilson, called attention to the absence of a lag between the observed light minimum of a Wolf-Rayet star which happens to be also an eclipsing binary, and the computed time of conjunction as inferred from the velocities of the emission lines produced by atoms which must have required some time to reach that portion of the shell where conditions are suitable for their radiation. C. S. Beals, at Victoria, discovered that there are two kinds of Wolf-Rayet stars-one group in which carbon is abundant and another in which nitrogen predominates.

Stars with Bright Lines.—Some stars that are otherwise normal in spectrum, have bright lines of hydrogen and of other elements, in addition to the usual absorption lines. Sometimes these lines are broad, or even double; in other stars they are sharp and narrow. The broadening appears to be caused by Doppler effect but the nature of the motions involved is not the

same in all cases. In a large group of bright-line stars of classes B and A the motions are rotational in character, a tenuous shell of gas revolving around a normal star which itself has such a rapid axial rotation that it approaches (or perhaps even reaches) the condition of rotational instability. Several stars of this kind happen to be members of close eclipsing double stars. The occulting star in its path eclipses first the approaching lobe of the rotating shell, then the star itself and, finally, the receding lobe of the shell. In other stars the motions are those of expansion, as in Wolf-Rayet stars and in novae, and in still others they are of an irregular or turbulent character. In many stars the bright lines vary in the course of years.

Å separate group is formed of various stars of the cooler classes which also show bright lines of H, Ca II, Fe I, Mg I, Si I, etc. Even the sun has weak central emissions in the lines designated as H and K of Ca II and in other stars, like Arcturus, they are fairly strong. The origin of these emission lines is somewhat obscure. It is probable that they come from the outer regions of the atmospheres of the stars; but in a large subgroup of these stars, the long-period variables, several hydrogen emission lines are weakened by absorption lines in gases which lie at still higher levels. This is especially striking in the case of He in Mira Ceti, where this particular hydrogen line is greatly

weakened by overlying vapour of Ca II.

An interesting but small group of stars have spectra containing forbidden emission lines, i.e., lines which are not produced in the laboratory because the corresponding transitions are not permitted by the rules of the quantum theory. Some of these stars have weak continuous spectra upon whose background are seen numerous bright lines of H, Fe II, [Fe III], Fe III, [Fe III], [Fe V], [Fe VI], [Fe VII], and probably even [Fe X] and other elements. The bracketed designations of elements stand for forbidden lines, and the Roman numerals designate the state of ionization. Since the ionization potentials of these substances differ widely, by Saha's formula of ionization they could not all be observed in a gas of uniform temperature and pressure. The conclusion is that they come from different regions of a highly complex nebulous structure. P. W. Merrill found that most of these stars also show absorption bands of TiO. It is believed that they consist of three sources: a cool star, a hot companion and a gaseous mass in which the radiation of the hot star causes ionization and excitation. In some cases, like the star Antares, the binary can be observed directly. Its bright component is a cool giant, but it also has a faint, hot companion whose spectrum reveals for-bidden [Fe II]. Swings and Struve have found that in these stars the forbidden lines of [Fe II] and those permitted lines of Fe II whose energy levels are low are abnormally strong, so strong, in fact, that an impossibly low excitation temperature results when the intensities are interpreted by means of the Boltzmann exponential relation. The conclusion is that the mechanism of excitation consists in collisions between atoms and electrons, and not in the process of line absorption or ionization. Most of these spectra undergo rapid variations, sometimes in the course of a few days.

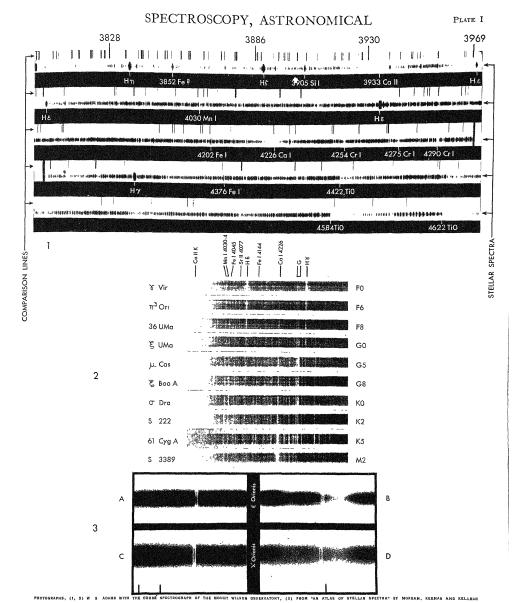

Spectra of Shells .- In 1938 the spectrum of the star Pleione, one of the brighter members of the cluster of the Pleiades, underwent a sudden change. For about 30 years the spectrum had been that of a normal B star with very diffuse absorption lines of H and He. It now developed emission lines of H and a set of sharp absorption lines of H, Fe II, Ti II, Ca II and other ionized elements. In the course of several years these sharp lines became very strong and indicated a tendency toward lowered ionization. A number of other stars which possess similar spectra are known, though they have not often been observed in the process of formation. The source of these spectra is designated as shells because it is inferred from the reduced intensities of a few characteristic lines that the gases in which they are formed are not at the surface of the star but are removed above it to several times its radius. The phenomenon producing these lowered intensities is designated as "dilution of radiation." To obtain normal intensities the populations of the different atomic levels must correspond to Boltzmann's relation. If the mechanism of excitation is the absorption of radiation this happens only when the radiation corresponds to conditions of thermodynamic equilibrium. When a gas is illuminated by a distant star the radiation is "diluted" and those excited energy levels which possess transitions to lower terms are depopulated in the same ratio that the apparent area of the star as seen from the gas bears to the complete sphere. The phenomenon of dilution causes the lines of Mg II 4481 and Si II 4128, 4131 to appear abnormally weak. It also produces remarkable changes in the relative intensities of the He I lines. The formation of shells seems to be related to the process of axial rotation of the stars. In some shells (f Tauri and  $\phi$  Persei) the shell is stratified and different layers of it revolve at different speeds around the main body.

Novae.—Few astronomical phenomena can compare in spectacular interest with the outburst of a bright nova. The spectra of these stars show very rapid changes. Prior to its outburst the spectrum is as inconspicuous as the star itself. But in a few hours, when the light suddenly increases several thousandfold, the spectrum becomes that of a rapidly expanding shell.

At first the shell shows mostly absorption lines which are greatly displaced toward the violet, because in the early stages the exploding gases are still largely projected upon the disc of the star, and we observe only the absorbing action of those regions which are being ejected in our direction. Gradually numerous broad undisplaced emission lines appear in the spectrum and rapidly increase in intensity. Usually several distant expanding shells are formed, each having its own velocity of expansion. The bright lines of the metals which appear early in the history of a nova gradually give place to those of the lighter elements. like H, O and N. The forbidden lines of [O III] become particularly strong and often cause the star to appear conspicuously green when observed through the telescope. D. B. McLaughlin has shown that all normal novae follow a definite pattern of spectral evolution, the character of which depends upon the duration and the violence of the outburst. The amount of matter lost by a nova during its outburst is a very small fraction of the total mass of the star.

A totally different series of changes is presented by the supernovae, whose visual brightnesses may suddenly increase by a factor of 100,000,000 times, while ordinary novae vary about 100,000 times. R. Minkowski has investigated the spectra of several of these objects, many of which have been discovered by F. Zwicky on photographs of remote galaxies. Statistical considerations show that the outburst of a supernova in our galaxy may be expected once every 600 years. The spectra of the most luminous supernovae show unresolved features which may be emissions or absorptions, or both. No satisfactory identifications of these features have been made. In the less luminous supernovae, F. L. Whipple and Mrs. C. H. Payne-Gaposchkin have found evidence of some of the same bands which are present in ordinary novae but which are broadened by expansion to a much greater extent than in the latter (about 5,000 km./ sec., as against about 1,000 km./sec.). There are many unexplained features, such as a variable red shift discovered by Minkowski, but it is difficult to study these stars because of their small apparent brightnesses. It is possible that the so-called Crab nebula has resulted from a supernova in our galaxy.

Pulsating Stars.—Among the stars whose radial velocities undergo periodic changes are the variables of the Cepheid and the long-period groups. The former have velocity curves which may be described as the mirror-images of their respective light curves. The variations in velocity are not caused by orbital motion, as in ordinary binaries, but are believed to be produced by periodic pulsations. The periods vary from a small fraction of a day to about 50 days. The spectral classes also undergo periodic variations, being hottest near maximum light, or near minimum radial velocity. There is conflicting evidence from the luminosity criteria but the hydrogen lines give maximum luminosity near maximum light; this correspondence is not physically obvious because the observed change in brightness (of the order of one stellar magnitude) is fully accounted for by the variation in temperature, and

Stellar spectra. All spectra are shown as negatives: the absorption lines appear white on a black background

- Appear wither the autonomous background of a control of the control of the control of a control
- A part of the spectral sequence showing the gradual changes in line intensities for several subdivisions in spectral class between FO and M2 in stars of moderate luminosity
- Multiple interstellar absorption lines in two stars: Ca II K in (a) and (o); Ca II H in (b) and (d). The very broad and diffuse line in (b) and (d) is the stellar line H€

the elementary pulsation theory would predict maximum radius and, hence, minmum atmospheric pressure halfway from minimum toward maximum radial velocity. Evidently the hydrogen atmosphere is expanded at the time of maximum light, and the phenomenon is only indirectly related to the pulsation. The long-period variables are probably also pulsating stars. Their spectroscopic changes have been described principally by P. W. Merrill and A. H. Joy at Mount Wilson. All of these stars show a fairly close relation between period and average spectral class, and a close relation between period and luminosity. Probably lelated to the long-period variables are several other groups of variable stars, designated as the irregular and the semregular variables. The spectra of these stars show interesting changes. Many of them, like the long-period variables, have strong, variable emission lines. The Cepheid variables show emission lines in very few

Abundance of Elements.—The question has often been asked whether the two-dimensional spectral classification outlined previously is sufficient to classify every normal star within the precision of modern spectroscopic measurements. The importance of at least one additional parameter, namely, abundance of atoms of different elements, is strongly indicated by a number of data. The question is difficult because nearly all the observed differences in the line spectra of the stars are caused by differences in temperature and pressure But there are a number of striking cases where these parameters appear to be insufficient. Thus, R. H. Curtiss, and later H. N. Russell, showed that the predominant appearance of TiO in classes K and M, and of compounds of C in classes R and N is probably caused by real differences in the abundances of O and C.

Russell's calculations found an interesting application in the work of L. Berman on the spectrum of the irregular variable R Coronae Borealis. In this star the H lines are much weaker than is consistent with its class, while the features due to C are too strong. Berman found that among the elements present in its atmosphere carbon contributes 69%, hydrogen 27%, nitrogen less than 0.3%, and the metals about 4% by volume. In the

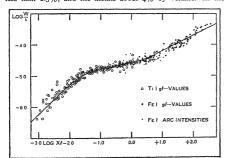

FIG. 3.—THE CURVE OF GROWTH OF THE SUN'S SPECTRUM ACCORDING TO K. O. WRIGHT

The abscissa are logarithms of the relative numbers of atoms (here designated as  $X_i$ ) effective in producing the line and which can be inferred from multiplet and supermultiplet relations in spectroscopy, or from laboratory measurements. The ordinates are logarithms of the equivalent width (W) of the lines divided by their wave lengths (A). The curve is profully local to  $X_i$  in its lower left portion and is proportional to  $\sqrt{X_i}$  in its upper right portion. The bending over is the result of the thermal motions of the atoms in the sun's atmosphere

sun D. H. Menzel finds 82% of hydrogen, 18% of helium, 0.003% of carbon and 0.01% of nitrogen.

Another interesting case of abnormally low bydrogen abundance was observed by I. L. Greenstein in v Sagittarii. The compromise class of this star is A, which is usually characterized by very strong lines of H. In reality these lines are very weak It turns out that He is about roo times as abundant as H, and H is about roo times as abundant as Fe. But the great majority

of the stars and nebulae have abundances similar to that of the sun, with hydrogen about 8,000 times more abundant than all the metals taken together.

In addition to differences of abundance there are several other small factors, as yet unexplained, which cause a certain amount of uncertainty in the spectral classification. These factors are quite unimportant when the purpose of the classification is to serve in the study of the structure of the galaxy and of its statistical properties. But they assume great interest in purely astrophysical studies. Among them are the following: (a) among the hotter stars (class B) there are some, like the star Maya in the Pleiades, which have abnormally weak lines of all elements; (b) among the stars of class A the spectral sequence divides out into several parallel branches; one branch is characterized by strong lines of Si II, others are strong in Mn II or in Sr II, still others have weak Ca II or strong metallic lines. It is not possible to reconcile these differences with the theory of ionization, and it is not reasonable to suppose that such striking differences in the abundances of the elements affect only this particular portion of the spectral sequence.

Cor Caroli Stars.—A remarkable group of stars of intermediate class shows abnormally strong lines of rare earths, especially Eu II and Gd II. In some of them the lines of the rearcearths are variable in intensity, while in others there are periodic variations in the intensities of lines of Cr II and of other lines commonly present. The best known representative of this group is Cor Caroli, whose period is five and one-half days. P. Swings has found strong lines of doubly ionized rare earths, in addition to the singly-ionized elements The variations are not easily explained by the theory of ionization as changes in temperature and pressure, and the velocity curves, which are different for different elements, are neither those of binary motion, nor those of ordinary pulsation.

Spectroscopic Binaries.-Unusual spectroscopic phenomena have been observed in a number of close double stars not otherwise identified with one of the preceding groups. Among these are the following: (a) In several eclipsing variables consisting of supergiant components which eclipse one another, the light of one component is observed to shine through the extended atmosphere of the other (5 Aurigae). In one case (6 Aurigae) the light of the brighter and smaller component shines through a considerable thickness of the substance of the larger and fainter component. Incidentally, this fainter component has a diameter about 3,000 times that of the sun and a temperature low enough to classify it as an infra-red star. (b) The absorption lines of several eclipsing variables show changes in intensity and distortions of their velocity curves, which indicate the presence in these systems of streams of gas which do not strictly belong to either component but which flow in complicated orbits through the system. (c) A combination of these streams with a spiral of outflowing gaseous material satisfactorily accounts, according to Struve and Kuiper, for the complicated changes in emission and absorption lines of  $\beta$  Lyrae. (d) There is a well-known tendency among components of close double stars to have more nearly similar spectra than is predicted from other considerations. This is attributed to the reflection of light of one component by the other. The reflection effect probably causes asymmetry in the profiles of spectral lines (fainter component of α Virginis). (e) There are peculiar periodic variations in the relative intensities of components of double-lined spectra, which have not been ex-

## LINE PROFILES

By means of a spectrophotometer it is possible to measure the intensity of a star's radiation at successive wave lengths, from one edge of a spectral line to the other. When the results of these measurements are expressed in units of the intensity of the continuous spectrum in the immediate neighbourhood of the line and are plotted as ordinates against the wave lengths as abscissae, the resulting curve is designated as the profile (or contour) of the line. The unit can, of course, be given in ergs per cm², per sec, if the effective temperature of the star is known and if

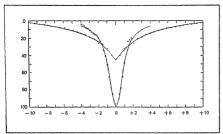

Fig. 4 —PROFILES OF THE HYDROGEN LINE  ${\rm H}\beta$  in a star of low atmospheric pressure (e. aurigae) and in one of high atmospheric pressure ( $\gamma$  peass)

The broadening is caused by the combined Stark effect of charged electrons and ions upon the radiating atoms of hydrogen. The abscissas are angstrom units and the ordinates are percentages of abscrption

the only approximately correct assumption is made that the star radiates as a black body. The profiles of faint lines are strongly affected by the finite resolving power of the spectrograph. For these it is customary to integrate the profiles and to express them in units of one angstrom of complete absorption. These values are designated as the equivalent widths of spectral lines. But for strong lines, like those of Ca II in the sun, the hydrogen lines in the A stars, etc., it is possible to derive physically significant profiles whose interest consists in the information they yield concerning the variation of the lineabsorption coefficient with wave length and the character of the propagation of light through the atmospheres of the stars. Important information can be obtained from a curve in which the equivalent widths of the absorption lines are plotted as ordinates against the corresponding numbers of atoms effective in producing each line, as abscissae. Such curves are designated as curves of growth because they indicate the manner in which the intensity of a line grows as the numbers of atoms are increased.

Radiation Damping.-Many lines, like those of Ca II, in the sun, have broad profiles with very deep, narrow pointed centres, where the residual light is only from 1 to 10% of the continuous spectrum, and with wings which extend very far to both sides (fig. 2). These profiles are well represented by an absorption coefficient which is inversely proportional to the square of the distance from the centre of the line. Physical theory suggests that this is the common form of the absorption coefficient of a single, undisturbed atom, where the gradual damping of the radiation in consequence of the loss of energy is the sole broadening influence. Since the mathematical form of this expression is known for a single atom of Ca II, it is possible from the observed profile to derive the number of absorbing atoms of Ca II per cm2. in the atmosphere of the sun. This was first done by Unsöld, who used earlier measurements by K. Schwarzschild. In some spectral lines, for example, those of Mg I in the sun, or some lines of He I in B stars, the profiles are similar in shape to those given by radiation damping but their widths are much greater-just as though the constant of the formula were several times as great as that predicted by atomic theory. This phenomenon is explained by the effect of collisional damping, which was first introduced into physical theory by H. Lorentz and later extended by Weisskopf and Wigner to include processes where atoms do not actually collide, but experience close approaches to one another. This form of broadening is important in dwarf stars of low luminosity, and is unimportant in giants of high luminosity. In both types of broadening the equivalent width of a line increases as  $\sqrt{N}$ , where N is the number of absorbing atoms. For example, we know that the line K of Ca II is formed by twice as many atoms as the line H. In consequence the equivalent widths of the two lines in the sun are in ratio  $\sqrt{2}$  to 1.

Thermal Doppler Effect.—In a stellar atmosphere the atoms because of the symmetrical form of the Stark effect splitting in are never quite undisturbed. They are moving about in all directions. H. this was not sufficient to prove the existence of Stark effect

tions because of the high temperatures prevailing in these regions, and these motions are presumably in accordance with statistical theory. Although every single atom radiates in accordance with radiation damping, some atoms are approaching while others are receding. The fraction which moves with a velocity v is, in accordance with Maxwell's law (see Kinetic Theory of Matter), proportional to  $e^{-(v/v_0)^2}$ , where  $v_0$  measures the average speed of the atoms. But if an atom moves with a velocity v in the line of sight it absorbs not in the normal position of the line but at a distance of  $\Delta \lambda = \frac{\lambda - v}{2}$ . If  $v_0$  were very large, then

radiation damping would be relatively unimportant. The profiles would be bell-shaped, in accordance with Maxwell's formula, and the equivalent widths would increase as N, and not as  $\sqrt{N}$ . For normal stellar temperatures radiation damping predominates for all but the very faintest lines. We therefore have a gradual transition in the relation between equivalent width and N, at first it varies as N, then as  $\sqrt{N}$ . The corresponding bending of the curve of growth, as this relation is called, was observed in the sun by Minnaert, by Allen and by others. (Fig. 3).

Turbulence.-The curves of growth of many stars, such as a Persei or  $\epsilon$  Aurigae, show a transition from the N to  $\sqrt{N}$ relation at an equivalent width which is much too large to be explained by thermal motions. Moreover, these curves show a region of transition between the two major branches of the curve of growth, where the equivalent width changes little with N, and remains almost horizontal. This phenomenon, first noticed by Struve and Elvey, is explained in terms of turbulent motions in the atmospheres of the stars. It is not known how large the volumes of gas are which are subject to these motions but they must be considerably smaller than the entire depth of the atmosphere, because otherwise the phenomenon would manifest itself differently in the curve of growth and would suggest convection. and not turbulence. The largest average turbulent velocity measured is about 67 km./sec., for the star 17 Leporis. The best analogue on the earth are the thermals which form on sunny days, but it must be remembered that the causes of the two phenomena are not the same.

Stark Effect.—In the presence of an electric field the spectral lines of many atoms are disturbed. In hydrogen the lines are split into several components, in helium some lines are little affected while some are displaced toward the red and others are displaced toward the violet and completely new lines, never seen without electric fields, appear in the spectrum. It has never been

possible to detect even the slightest evidence of a uniform electric field in the sun or stars. But the atmospheres of all stars contain vast numbers of charged particles, namely, free electrons and ions, each of which carries its electric charge and may in its thermal flight through the atmosphere come close enough to a radiating atom to produce an appreciable Stark effect. We observe a combination of countless cases of this sort, with all possible distances between neighbouring particles and all orientations. The observed line should therefore have a blurred appearance,

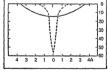

FIG. 5.—PROFILES OF THE LINE MG II 4481 IN VEGA (----) AND IN ALTAIR (-----).

The line in Altair is broadened by the rapid rotation of the star. These profiles were obtained from the spectrograms shown in Plate II (9 and 10). The abscissar are angstrom units, and the ordinates are percentages of absorption of the continuous spectrum

and its form can be predicted by a combination of statistical and physical theories.

The profiles which result from an application of the theory by Doppler effect. The wings are exceedingly broad and the centres of the lines are appreciably raised, so that the residual intensities may be as great at 50% of the continuous spectrum. Such profiles are observed in the hydrogen lines of dwarf stars, but because of the symmetrical form of the Stark effect splitting in the hydrogen spectrum of Stark effect of the symmetrical form of the Stark effect splitting in the hydrogen spectrum of Stark effect.

m stars. The proof came when the lines of He I in B stars were found to show appreciable broadening in those lines which are sensitive to electric fields and no broadening in those lines which are not sensitive to it. Stellar spectra also show several of the new lines forbidden by the quantum theory in the absence of fields; and the permitted lines show systematic shifts m accordance with the theory. The Stark effect is appreciable in ordnary dwarfs and is very large in white dwarfs. It can be used to determine the luminosity of a star, because of the close relations between this quantity and the atmospheric density.

Rotation.-In many stars, especially of classes O. B. A and F. all lines appear blurred, even those which are not sensitive to Stark effect, while at the same time the curve of growth shows no appreciable turbulence. The equivalent widths of the lines are not altered by this broadening influence and the great widths are obtained at the expense of the central intensities. In some cases it has been shown that the widths of the lines are proportional to the wave lengths, if corrections are made to reduce them to the same equivalent width. Since the Doppler effect is proportional to \(\lambda\) and since no physical alteration of the absorption coefficient can fail to influence the curve of growth, or the equivalent widths of the lines, the conclusion is justified that we are dealing with some form of Doppler effect. Axial rotation. radial expansion and convection suggest themselves. The effect of expansion is to produce an unsymmetrical profile which is deepest at the point of greatest negative displacement  $\Delta\lambda_0$ , and merges with the continuous spectrum at  $\Delta\lambda = 0$ . Since we can see only one hemisphere of an expanding star, the line does not extend into positive values of  $\Delta\lambda$ . Neither the asymmetry nor the preference for negative displacements agrees with the observations. We are left with rotation and convection.

To decide between them Struve and Shajn made numerous determinations of line profiles in close spectroscopic binaries. In these stars the components are almost in contact and it is reasonable to suppose that their rotational periods are equal to the period of orbital revolution. All have very broad and shallow lines, and this phenomenon is the more conspicuous the shorter the period. Since no such relation is expected in the case of convection, the "dish-shaped" line profiles can be attributed to axial rotation. In a few eclipsing binaries, for example in Algol, the line profiles become unsymmetrical during the partial phases of the eclipse and, as Rossiter and McLaughlin have shown, it is possible to derive from them the rotational velocity at the equator. The observed values range from o to about 300 km./sec., with a few which exceed this value.

A statistical study of the frequencies of different rotational velocities shows that the stars do not all rotate uniformly, and the observed distribution is not simply a result of random orientations of the axes. The largest values are observed in several bright-line B stars. When the bright-line stars are considered alone, the distribution does seem to be due to the geometrical factor alone. It is probable that the rotations of all of these stars are so rapid that they may actually lose material at their equators. In a general way, according to W. W. Morgan, the broadest rotational lines occur in stars of low luminosity and the lines become progressively narrower with increasing luminosity. In all close spectroscopic binaries observed prior to 1945 the direction of axial rotation is the same as that of orbital motion, but in a few close systems (U Cephei) the rotational period is shorter than the orbital period.

Central Intensities.—It has been previously stated that even in those lines which are strong enough and broad enough not to be seriously affected by the finite resolving power of the spectrograph the central intensities are not exactly zero, and this remains true after instrumental corrections have been applied. Very accurate central intensities in solar lines have been measured by C. D. Shane at the University of California, who used an interferometer to increase the purity of the spectrum. The origin of these central intensities is interesting; according to physical theory the line-absorption coefficient never becomes infinitely great. Yet, the value predicted by radiation damping is so great that the ordinary absorption formula \$I10=e^{-kt}\$, where

k is the absorption coefficient and l is the length of the path in the absorbing medium, would require that the central intensity to be so small that it could not be observed to differ from zero.

We are here concerned with a problem of great importance, namely, the manner in which the radiation is propagated through the star's atmosphere. The corresponding theory has been developed by Karl Schwarzschild, Edward A. Milne, Arthur S. Eddington, Bengt Stromgren, A. Unsold, S. Chandrasekhar and others. The fundamental difference from the ordinary formulation of this problem comes from the fact that the atoms not only absorb, but they also re-emit radiation, and that this re-emitted radiation is thrown in all directions, while the absorption takes place in radiation directed outward from the star The central intensities in a star which is devoid of an extended chromosphere come from this re-emission. In a shell, like that of Pleione, where the absorbing gas is very far from the source of the continuous spectrum, the photosphere, only a small fraction of the re-emitted radiation is projected upon the apparent disk of the star, as would be seen by the observer if he had a sufficiently large telescope. Hence the absorption process is essentially that described by the exponential formula, and the central intensities are so close to zero that they have not been measured. But in a normal star of approximately the same temperature the central intensities may be as high as 50% of the continuous spectrum. There are two possibilities: an atom may, after a process of absorption, immediately re-emit the same line: this is the case of pure scattering. Or the atom may after a process of absorption lose track of the quantum, allowing it to be absorbed again and re-emitted a number of times, so that the energy which finally is re-emitted by the original atom is a kind of statistical average over all possible processes and is then determined by the Kirchhoff-Planck function. This is the case of pure absorption. In reality, both cases may be realized in the stars. Lines of high excitation potential, like those of H and He, probably ap-

In reality, both cases may be realized in the stars. Lines of high excitation potential, like those of H and He, probably approach the second case, while resonance lines, like H and K of Ca II, approach the first case. Schwarzschild has shown that for pure absorption the central intensity is that which corresponds to the temperature of the outermost, and hence, the coolest layers of the stellar atmosphere. This, incidentally, is also the intensity of the continuous radiation at the extreme limb of a star's disk. Hence, if we observe the central intensities of H and He I in a B-type star we obtain a measure of the darkening of the star's continuous radiation from centre to limb.

Unsöld found that in the star  $\tau$  Scorpli the central intensities which are almost 50%, are still too small to accord with the usual theory of the limb dalkening. He would have expected an even higher central intensity. The discrepancy can be used to improve the theory of the continuous absorption coefficient, which determines very largely the phenomenon of limb darkening.

Some puzzling differences in the central intensities of lines of Fe I were found by L. Spitzer, Jr., in  $\alpha$  Orionis and several similar cool supergiants. There is a pronounced tendency for the central intensities to be greater as the excitation potential increases, and there are several abnormally shallow lines. The latter are members of multiplets whose other members behave normally, but they all happen to have identically the same upper level. There is good reason to believe that this particular level is overpopulated because it is fed by a special process pointed out by A. D. Thackeray—there is a strong line of Mg II 2705.52 which almost coincides with the Fe I line 2795.00. If the former were in emission-it cannot be observed because it lies too far in the ultra-violet-this would stimulate the absorptions in the Fe I line and overpopulate the required level. Such abnormal re-emissions are designated as fluorescence. In some late-type variables the abnormal Fe I lines appear actually in emission, while the other members of their multiplet are present only in absorption.

Convection.—Adams and his co-workers at Mount Wilson have found that in many stars—especially in giants and super-giants—there are appreciable differential radial velocities between different sets of lines. In some M-type supergiants many lines are double, while others are single. In a Orionis the violet

components are sharp and strong, while the red components are weak. All the double lines arise from very nearly the ground state of the neutral or ionized atoms. This phenomenon is undoubtedly caused by differential motions within the enormously extended atmosphere of the supergiant star. Similar motions may account for the differences in displacement between absorption and emission lines in M-type variables, as observed by Merrill,

Joy, and others.

Centre to Limb Differences .- The most powerful method for testing theories of line formation consists in the study of line profiles at different distances from the centre of the sun. K. Schwarzschild showed that if a line is produced by the re-emission process designated as pure absorption, it should completely disappear at the extreme limb of the sun; in the case of pure scattering, on the other hand, the line should persist at the limb. From the measurements by Schwarzschild, H. H. Plaskett, Miss M. G. Adam, J. Houtgast, M. Minnaert and others, it is known that all strong solar lines become somewhat weaker at the limb but they do not disappear (fig. 2). Very faint lines, however, not only do not show this weakening but they even become slightly stronger. The interpretation of these observations is difficult and involves a number of physical data which are not available. The most extensive work on the interpretation of solar lineprofiles is by B. Strömgren. In the stars we usually observe line profiles integrated over the entire disk. But in a few eclipsing variables in which a large, dark star centrally eclipses a small, bright star there is a chance of observing the spectrum from the limb of the small star immediately before and immediately after totality. In this manner R. O. Redman, and later O. Struve, found some evidence that the lines of hydrogen almost disappear at the limb of the hot component of U Cephei.

# GASEOUS NEBULAE

The spectra of the gaseous nebulae consist of a weak continuous spectrum and a set of strong emission lines. The former shows a conspicuous discontinuity at \(\lambda\) 3647 and is therefore, in part, caused by the process of recombination of protons with free electrons. But the continuous spectrum of some of the nebulae in the ordinary photographic region is too strong to be entirely due to the Paschen continuum. It is probable that most, if not all, of it is caused by diffuse scattering of starlight by small solid particles in the nebulae. The line spectra contain many features which were not identified previous to 1927. In that year I. S. Bowen attributed all the principal "nebulium" lines to forbidden transitions between metastable levels of some of the more common atoms, [O II], [O III], etc.

From the work of E. Hubble it is known that the nebulae derive their light from hot stars located within their confines. The ultra-violet continuous radiation of these stars, especially that on the violet sides of the Lyman limit of hydrogen and the corresponding limits of He I and He II, is absorbed by the atoms of the nebula. In this manner the principal permitted lines are excited because they are radiated when the excited atoms fall back, either directly or by cascading, to their ground levels. In the process of cascading some atoms will find themselves in the low-energy metastable levels, where they are caught for a long time because there are no further permitted transitions downward. The atoms can get out only by one of three processes, all requiring long intervals of time; they can swallow another quantum of energy and return to a higher level; they can collide with another particle and make use of the kinetic energy of the collision to escape the trap; or they can patiently await their release in the form of a forbidden transition which, despite its name, is not entirely impossible but occurs, on the average, once for every 108 permitted transitions.

In all laboratory experiments collisions are too frequent to allow enough forbidden transitions to take place. In the atmospheres of the stars the radiation is so intense that quanta fly about everywhere in large numbers and atoms which find themselves in the trap have plenty of opportunity to get out by absorption. But in the nebulae, collisions are very rare and the density of quanta is low. Hence, large populations of atoms

accumulate in the metastable levels, and despite the relative infrequency of a forbidden transition the forbidden lines appear with great strength.

Bowen has shown that while the process of cascading will furnish appreciable populations in the metastable levels, the forbidden lines are relatively so strong, compared with the permitted lines of the same ions, that another process must also be postulated. It consists of collisions of unexcited ions with free electrons. Although collisions are insufficient to remove an appreciable fraction of atoms from an excited level to a higher level, with a large change in energy, they are very efficient in producing small energy changes and, therefore, account satisfactorily for the observations. Bowen has discovered a third process of nebular excitation, namely, fluorescence. By a chance coincidence the wave length of one of the strongest (though unobserved) emission lines produced by the primary process of recombination, He II 303.780, agrees almost precisely with the permitted line O III 303.799. In consequence, the emission of He II stimulates an abnormally large number of atoms of O III to absorb and to jump to the upper level of the O III line. Hence, they cascade downward, producing strong lines of certain members of various multiplets, while other members remain invisible. These mutilated multiplets have been observed by W. H. Wright.

The energies contained in the emission lines of a nebula are the result of conversion by the atoms of ultra-violet continuous radiation of an exciting star. Since the former can be measured, we obtain a measure of the unobservable ultra-violet light of a hot star; on this basis H. Zanstra has developed a theory for determining the temperature of the exciting stars. This method in the hands of D. H. Menzel and his associates gave excellent results and led to the realization that while the temperatures of the stars range from 3,000° to 100,000°, the electron temperature of the nebular gas is usually of the order of about 10,000°. The farthest ultra-violet continuous radiation of the star is absorbed in its immediate vicinity. Hence the lines of He II are limited to a small volume around the star. On the other hand, elements of lower ionization potential, like He I and H, occur at greater distances. This gives rise to an apparent stratification in the nebulae. Of great interest are the absorption lines of He I observed by O. C. Wilson in the Orion nebula. All these lines have metastable lower levels.

A subject closely related to that of the nebulae is that of interstellar gas. It manifests itself in two forms: as absorption lines of abundant elements in their ground levels, observed on the background of the continuous spectra of distant stars, and as emission lines of H, [O II], [N II], etc., in many large areas of the Milky Way. The emission lines, as well as the absorption lines, are produced through excitation by the combined light of the stars.

The density and the temperature of this field of radiation can be computed for the neighbourhood of the solar system. Since we observe interstellar lines of Ca I and Ca II, we can form the ratio w'/n in Saha's ionization formula, appropriately amended for the effect of dilution in the radiation. We then have only one unknown quantity, the electron pressure. This turns out to be equivalent to about 10 electrons per c.c., a value which is consistent with the observed surface brightness of luminous hydrogen over large areas of the Milky Way.

C. S. Beals, R. F. Sanford and W. S. Ádams have found many stars with multiple interstellar absorption lines showing that the gas consists of clouds having individual motions. Andrew Mc-Kellar, Theodore J. Dunham, Jr., Walter S. Adams and G. Herzberg have found and identified several interstellar molecules, such as CH. CH<sup>\*</sup>, and CN.

A theory of interstellar emission has been developed by B. Strömgren. Because of the gradual exhaustion of the ionizing stellar radiation in the gas he added a term to Saha's formula to take care of this exponential absorption. It turned out that the boundary between the region where H is ionized and the region where it is unionized is fairly sharp. The regions of ionized hydrogen are identified with the observed areas of luminous hydrogen.

#### PLANETS AND COMETS

The planets shine by reflected light and their spectra show the usual solar spectrum; the distribution of continuous energy is modified by the colour of their surface structures or by the scattering of their atmospheres. The solar lines are displaced by the orbital and rotational motions of the planets and, in addition, there are absorption bands produced in these atmospheres. Measurements of radial velocity have been extensively used to determine the periods of rotation, especially in the case of Neptune and the law of motions of the rings of Saturn. Differential radial velocities between the planet and the earth are also important to distinguishing between absorption bands of water vapour and of oxygen, which are strong in our own air.

Adams concluded in 1941 that water vapour, if at all present on Mars, constitutes not more than 5% of that in air, and probably very much less. Nor is there any free oxygen in excess of that in air. But the red colour of the desert areas on Mars suggests the existence of large quantities of oxygen in the form of compounds, such as rust. There may also be enough water vapour to give rise to thin sheets of ice at the polar caps.

Adams and Dunham found two new bands of carbon dioxide on Venus, while A. Adel and V. M. Slipher estimated that the amount of carbon dioxide above the cloud layer of Venus is several hundred metre-atmospheres. The spectra of Jupiter, Saturn, Uranus and Neptune show conspicuous bands in the red and infrared regions. They were identified by R. Wildt in 1932 as ammonia and methane. Several successful attempts have been made by Dunham and by Adel to determine the temperatures from the distribution of intensity in the various bands. Thus, for Venus, Adel found so? C., from the carbon dioxide bands. The ammonia band is strongest in Jupiter, and becomes progressively weaker in Saturn, Uranus and Neptune. The methane bands, on tures Thus, for The the other hand, increase greatly from Jupiter, with 0.5 mile-atmosphere (amount of gas whose absorption of light is equivalent to a mile-long column of the same gas at standard atmospheric pressure), nme-ong count of the same gas at standard atmosphere, pressure), to Neptune, with 25 mile-tamospheres, according to Slipher and Add. In 1944, G. P. Kuper found the bands of methane on the largest satellite of Saturn, Titan. They are a little weaker in the satellite than in the planet. None of the other satellites in the solar system, nor pluto, shows any of the bands with the spectrograph used by Kuper

The spectra of the comets are characterized by emission bands of CN, C2, CH, OH, NH, CH<sup>+</sup>, CH2 in the heads, CO<sup>+</sup> and Na<sup>+</sup> in the tails. P. Swings has shown that the bands are excited by solar radiation. Since the latter is not uniform, like that of a black body, but is broken up by many strong absorption lines, the excitation to various molecular levels in the comet is quite abnormal, and the resulting intensities of the individual lines within the bands are dif-

ferent from those observed in the laboratory.

### THE SUN

Since a separate article on the sun (q v.) contains a description of its spectrum, only the principal features have been briefly mentioned in the foregoing sections to the extent to which they are valuable in turnishing independent information to the study of astronomical spectroscopy. There remains, for completeness, the problem of the spectroscopy. There rem spectrum of the corona.

The corona consists of an inner zone having a continuous spectrum, ionization level in the sun's atmosphere is about 8 volts. If we insert ionization level in the sun's atmosphere is about a volts. If we have these values, one after the other, in the ionization equation and use the same value of  $T=5040^\circ$  C, which is approximately correct for the sun's atmosphere, we obtain  $\log_{10} p_c/p_c=806$ . This is impossible, since there would not be enough gas left to show any lines. Evidently we must adopt for the corona a very much higher temperature, perhaps one of the order of 1,000,000, to obtain a reasonable pressure. The origin of this high temperature is not known. Because of the extremely tenuous nature of the corona, this high temperature ot the extremely tenuous nature of the corona, this high temperature does not make itself felt on the earth; what we experience as the heating action of the sun is the radiation of the photosphere whose temperature is more nearly 6,000°. The strongest coronal lines,  $\lambda\lambda$  5,903, 6,975 of [Fe XIV] and [Fe X] and some others, were found by Adams and Joy in the peculiar star RS Ophiuchi. Thus, there is a link between the spectra of the stars and that of the solar

SPECTROSCOPY, X-RAY. The discovery by Max von Laue in 1912 that X-rays could be diffracted by crystals created a new branch in spectroscopy. Whereas the ruled gratings with linedistances of say 1/1,000 of a mm, are powerful tools to register the ordinary optical spectra with wave-lengths down to about 2.000 Ångström units (10-8 cm.), the natural crystals with distances between the atomic layers of a few A. units may serve as diffraction gratings for the radiation belonging to the domain of the X-rays with wave-lengths of the order of 10 to 0.1 A. units.

These figures for the wave-lengths studied by ruled gratings and for the region accessible with crystal gratings show that there was a considerable gap from about 2,000 to 10 Å.U. left. As will be seen later in this report methods have been developed which allow a registering also of this intermediary region.

Historical Remarks .- That the X-rays produced in an ordinary X-ray tube are complex and differ in quality when the vacuum of the tube, or primarily the tension on the tube, is varied was noted by Röntgen himself in his first papers dealing with the new radiation. It was shown early that the X-radiations became more penetrative as the tension of the tube was raised. The degree of penetration (usually measured in terms of the thickness of aluminium necessary to reduce their intensity by half) was used as a means of characterizing the quality of the radiation.

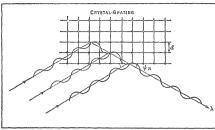

It was by this means also that C. G. Barkla was able to show that the different elements when excited so as to give off X-rays all have their own "characteristic" radiations. For instance for an element such as silver Barkla showed the existence of two "characteristic" radiations called the K- and L-radiation having very different penetrating power.

The K-radiation from this element is reduced to half its intensity after passing through a sheet of aluminium about 1 mm. thick whereas the L-radiation is diminished in the same degree after it has passed through only 0.004 mm. of aluminium.

These two characteristic radiations, the K-series and the Lseries, were experimentally verified for a great number of elements. The measurements of their penetration in aluminium showed that their "hardness" increases regularly for both series when the atomic weight of the emitting element increases.

Corresponding to the emission of the characteristic fluorescent radiation of a certain element, Barkla and his collaborators, especially Sadler, showed the existence of a remarkable abnormality in the absorption of the X-rays. This was the first indication of what is now called the absorption-spectra in the field of X-rays, and which have been shown to be intimately connected with the emission spectra or characteristic radiation of the elements.

Basis of the X-ray Spectroscopy.—The diffraction patterns which Friedrich and Knipping obtained on allowing a fine beam of X-rays to pass through a crystal as suggested by Laue induced W. H. and W. L. Bragg to perform experiments, which formed

the first step of the development of the X-ray spectroscopy As the Braggs showed, a monochromatic X-ray beam is reflected by a cleavage face (or any other atomic plane) of a crystal according to the ordinary laws of optical reflectuon, ie., the incident and the reflected beams are in the same plane and this plane is perpendicular to the reflecting face, and further the angles between these two beams and the reflecting face are equal. In addition to these laws the following condition must be fulfilled if reflection is to occur, namely:

$$n\lambda = 2d\sin\psi_n$$
 (1)

where  $\lambda$  is the wave-length of the monochromatic radiation, d is the distance between two adjacent atomic layers parallel to the reflecting plane,  $\psi_n$  the angle between the beam and the plane and n indicates the "order" of the reflection. (Fig. 1.)

This equation, generally known as Bragg's law, forms the basis for measuring the wave-lengths of X-rays. It may be mentioned that this law needs a small correction, due to the fact that the wave-length is slightly different in a vacuum (or air) than in the crystal.

Spectrometric Methods.—The arrangement for the spectroscopic analysis of an X-ray beam is shown diagrammatically in

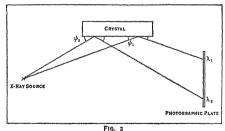

fig. 2. The different monochromatic rays which constitute the beam coming from the X-ray source (or slit) are reflected by the crystal at different angles and directions according to the Bragg law (1) as the angles may vary from  $\psi_1$  to  $\psi_2$  only such rays are reflected whose wave-lengths have values between  $\lambda_1$  and  $\lambda_2$  where

$$n\lambda_1 = 2d\sin\psi_1$$
  
 $n\lambda_2 = 2d\sin\psi_2$ 

On the photographic plate therefore there is found, after exposure and developing, a spectrum ranging from  $\lambda_1$  to  $\lambda_2$ . The region of wave-lengths can be varied by turning the crystal.

From the position of a certain spectral-line on the photographic plate its wave length is computed by equation (1).

Exciting of X-ray Spectra.—To excite the X-ray spectrum of a substance a small prece of it is placed on the anticathode (3a, 3b) of an X-ray tube After the tube has been exhausted to a suitable vacuum a high potential (10 to 150 kilovolts) is applied to the electrodes of the tube. By this means the anticathode is bombarded by the electrons forming the cathode rays. The kinetic energy of the electrons imparted to the bombarded atoms is partially transformed into heat, light, etc., and partially to X-rays. We will here deal exclusively with the last mentioned rays and more especially with the question as to how this radiation varies with the material on the anticathode.

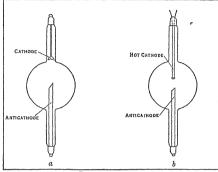

FIG 3 .-- X-RAY TUBES

As to the X-ray tube and its working there are two main ways of producing the cathode rays used for bombardment. In the first type (3a) the tube has a vacuum of o.or to o.oor mm. Hg. The high tension in this case gives rise to ionization of gas remaining in the tube and the positive ions formed are thrown against the cathode (of aluminium) and on their collision set free a number of electrons. The electrons travel in the opposite direction—from the cathode to the anticathode—and bombardment of the anticathode gives rise to X-rays characteristic of the substance of the anticathode. In the second type (3b Coolidge-tube) the vacuum of the tube is much lower.

In this case the electrons forming the cathode rays are supplied by the heated filament (usually of tungsten) in the cathode.

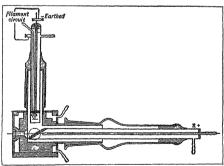

FIG. 4.-METAL X-RAY TUBE WITH HOT CATHODE FOR SPECTROSCOPIC USE

For analyzing purposes it is often necessary to change the substance on the anticathode and the tube must be built in such a way that the anticathode is easily detachable. This can be accomplished by mounting the anticathode in a special joint. A

tube—designed for spectroscopic purposes which permits rapid change of both cathode and anticathode is shown in fig. 4. The tube itself is built of metal with water cooling to permit a very high output of energy. Further a small window of aluminium or goldbeater's skin makes it possible to study the radiation of longer

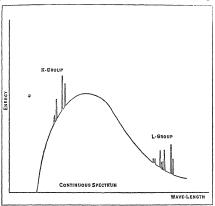

FIG. 5

wave-lengths which are absorbed by the glass walls of an ordinary tube

Another way of exciting X-ray spectra is to irradiate the substance with an intense beam of X-rays. In this case the substance emits "secondary" rays which, with a few exceptions, are identical with the X-radiation sent out by the same substance used as an anticathode in an X-ray tube. This method does not however give the same intensity as the former.

Different Kinds of X-ray-spectra.—The X-ray spectrum emitted from an arbitrary substance is built up of two kinds of radiation, one of which shows a continuous distribution over a wide range of wave-lengths, the other consisting of a few monochromatic rays overlapping the former (see fig. 5). The first mentioned radiation corresponds to the "white" light of ordinary optics, whereas the second is analogous to the line-spectra. The continuous spectrum contains the greater part of the energy of radiation and is therefore the most important part for medical and many other applications of the X-rays. This part of the X-ray spectrum shows qualitatively no dependence on the radiating substance, the intensity only being different from various anticathodes.

The line-spectra on the other hand are characteristic of the

FROM SIGGRANN, "SPEKTROSKOPIE DER RONTGENSTRAHLEN" (SPRINGER)
FIG. 6.—SPECTRUM FROM A COOLINGE TUBE WITH TUNGSTEN ANTI-

emitting substance. They correspond to the K- and L-radiation of Barkla, but analysis has shown that each of these radiations consists of a group of monochromatic spectral-lines.

In addition to the emission-spectrum of X-rays there is also an absorption-spectrum analogous to the absorption-spectra of ordinary optics. Such spectra are obtained when a sheet of thin foil of some substance is placed between the X-ray source and the photographic plate. Instead of a continuous blackening from the white X-radiation the plate shows one or more sharp edges where

there is a rapid change in the blackening—the so-called "absorption-edges". The wave-lengths of these absorption-edges show an intimate relation to the characteristic line-spectrum of the substance used as absorbing screen. Such absorption-spectra were first obtained by Duc Maurice de Broglie and given right interpretation by Sir William Bragg and M. Siegbahn Fig. 6 is a reproduction of a spectral-plate showing these three kinds of spectra.

The Continuous Spectrum.—As already mentioned the "white" or continuous radiation from an X-ray tube covers a rather wide region of wave-lengths. The diagrams of fig. 7 give an idea of the distribution of the energy of the different wave-lengths at voltages from 20 to 50 kilovolts. The curves of distribution always start at a definite minimum wave-length (\lambda\_{mm}). The value of this wave-length decreases with increasing voltage.

It has been found empirically and verified by many investigators that this wave-length  $(\lambda_{\min})$  or its corresponding frequency

$$\left(\nu_{\max} = \frac{1}{\lambda_{\min}}\right)$$
 obeys the Einstein law

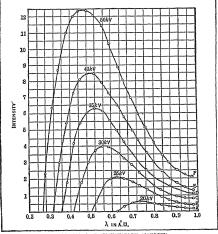

introduced the equation may be written

 $\nu_{\max} = \frac{e^{\nu}}{h}$  (2) where  $e^{\nu}$  is the charge of the electron, V the tension on the tube and h = Planck's constant. If the numerical figures of e and h are

$$\lambda_{\min} = \frac{12 \cdot 3}{V} \tag{3}$$

where the wave-length is expressed in  $\hat{A}.U.$  (10-8 cm.) and V in kilovolts

The total amount of energy, that is, the integral energy included by the distribution-curves in fig. 7, has also been measured

FROM SIEGBAHN, "SPEINFOSKOPIE DER RONTGENSTÄRLER" (SPRIKGER)
FIG. 7.--INTENSITY DISTRIBUTION OF THE CONTINUOUS RADIATION
FROM A TUNGSTEN ANTICATHODE AT VARIOUS VOLTAGES

by many investigators. As the result of these researches it can be stated that the total energy is proportional to the square of the voltage on the tube.

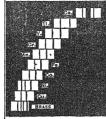

Further it has been found (by G. W. C. Kaye and others) that for different elements used as anticathode the total radiation is proportional to the atomic number of the element.

Already in the early days of X-ray technique it was found advantageous to use heavy elements as anticathodic materials for the medical X-ray tubes, an observation which is in agreement with the last general law.

The Line-spectra.—In 1913 and 1914 the young English physicist H. G. J. Moseley published two very remarkable papers

in the Philosophical Magazine entitled "The High-frequency spectra of the elements." The two papers contain the first announcement of the birth of a new branch of optics. Moseley showed in these publications that there existed in the realm of X-rays line-spectra of the same type as was known in ordinary optics and at the same time that these new spectra were built up in a much more simple and regular way than is generally the case in the spectra which had previously been studied.

Two groups of spectral-lines were found. One of these groups was identified with the K-series of Barkla; the other, of longer

FROM PHILOSOPHICAL NAG. 1913, SER. 6,
VOL. 26, PL XXIII (TAYLOR AND FRANCIS,
LONDON)
FIG. 8.—THE K-SERIES OF THE
ELEMENTS CA TO CU, AND OF BRASS

of Barkla; the other, of longer (Cu. Zn) wave-length and of more complex structure, corresponds to the L-series. Fig. 8 is a reproduction from Moseley's paper of spectra of successive elements from Ca (atomic number 20) to Zn (30). It shows in the most beautiful way how regularly the spectra—in this case the K-group—repeat themselves from one element to the next. With increasing atomic number (here from co to 30) of the emitting element the line-group is displaced in regular steps towards the shorter wave-length. This rule is not confined only to these elements and this group, but is universally confirmed by all X-ray spectra.

In 1916 M. Siegbahn discovered a new series of still greater wave-lengths called the M-series. The existence of series outside the K- and L-group had already been suspected earlier by reasons of analogy. In the later development of X-ray spectroscopy higher series, N, O, etc, have been found.

A general scheme of the X-ray spectra is given in the diagram go which contains the strongest lines of the three groups K, L and M at every third element from Na (11) to U (92). The diagram shows how all three series are regularly displaced to longer wave-lengths as one proceeds from the heavier elements to the lighter. If the spectrum of some special element, say Tungsten, a material commonly used for the anticathode, is considered, it will be seen that there are big gaps between the three groups where no lines are to be found. This fact is of predominant importance in interpreting the spectra in their relation to the structure of the atom.

As to the structure of the different groups it may be mentioned that the K-group generally consists of 4 lines  $(\alpha_1 \alpha_2 \beta_1 \beta_2)$  the L-group of more than 20 lines (the strongest lines designated by  $\alpha_1 \alpha_2$ ,  $\beta_1 \beta_2 \beta_3 \cdots$ ,  $\gamma_1 \gamma_2 \cdots$ ) and finally the M-group of about 20 lines.

Most of the X-ray spectra consists of a very easily absorbed radiation so that in using an ordinary X-ray tube they will no reach outside the glass-walls. In the diagram in fig. 9, only the small portion between the vertical lines o and r Å.U. includes the radiation given off by the technical X-ray tube. Hence for the study of X-ray spectra, one is confined to the use of tubes with thin foils as windows and spectrometers built for vacuum.

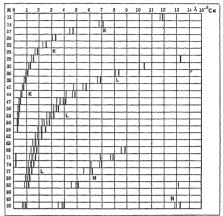

The Absorption Spectra.—As already mentioned the absorption spectra, obtained by putting a screen of the substance between the X-ray source and the spectral plate, usually have the appearance of a sudden, sharp drop in the blackening of the plate.

The study of these spectra has shown that there is always one absorption-edge in the region of wave-lengths where the K-group of the same element is located. In the region of the L-group there are three absorption-edges and finally in the domain of the M-group experiments have revealed five edges.

As to the K-absorption-edges the measurements of their wave-

lengths show that they have, if not exactly, very nearly, the same values as those of the line with the shortest wave-lengths within the K-group.

How the three absorption-edges of the L-group are located relative to the L-emission-lines is shown in figure 10. As seen from this diagram, here also the edge with the shortest wavelength agrees with the shortest emission-line. It is reasonable to suppose that the L-group may be divided in three sub-groups of

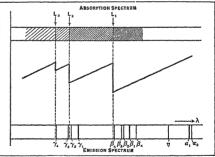

FROM SIEGBANN, "SPEKTROSKOPIE DER RONTGENSTRAHLER" (SPRINGER)
FIG. 9.—DIAGRAM SHOWING THE STRONGEST LINES OF THE SEVERAL
X-RAY SERIES FOR EVERY THIRD ELEMENT

lines of which every one is related to one of the three edges as is the case in the K-group. A numerical analysis of the material strongly supports this view as will be stated later.

Analogous results concerning the five edges within the M-group indicate the existence of five subgroups in this series.

Connection Between Emission- and Absorption-spectra.

—As soon as reliable measurements of the two kinds of X-ray

FROM SIEGRAMM, SPEKTROSKOPIE DER RONTGERNSTRAMLER" (SPRINGER)
FIG 10.—DIAGRAM OF THE ABSORPTION AND THE EMISSION SPECTRUM
SHOWING THE RELATIVE POSITIONS OF DISCONTINUITIES AND LINES

spectra, line- and absorption-spectra, had been performed it was clear that there existed a very intimate relation between them. If the frequencies of the absorption-edges are indicated by

K for the one absorption-edge within the K-group

 $L_1 L_{11} L_{111}$  for the three absorption-edges within the L-group  $M_1 M_{11} M_{111} M_{11} M_2$  for the five absorption-edges within the M-group it is found that the differences between some of these values give exactly the frequencies of some of the emission-lines. For in-

stance the differences  $K-L_{II}$  and  $K-L_{III}$  give the values of the frequencies of the two strongest lines of the K-group namely  $K\alpha_1$  and  $K\alpha_2$ . On calculating the difference between some of the above M-values and the K-value other lines belonging to the K-group are obtained.

In the same way a difference between  $L_D$   $L_H$  and  $L_{III}$  with some of the values of the higher absorption-edges ( $M_I$   $M_{II}$ ...) gives emission-lines of the  $L_{\rm F}$ orup. Now these connections between the absorption and emission-spectra allow an extension which seems highly probable. The frequencies obtained by calculating the difference between the three L-values and the M-values include only part of the L-emission-lines, but supposing the existence of higher absorption-frequencies  $N_I$   $N_{\rm III}$   $N_{\rm III}$ ...  $O_I$ ... of suitable frequencies the remaining L-lines may be accounted for as differences between absorption-frequencies. The existence of these higher absorption edges has not as yet been directly experimentally proved but they are strongly supported by the fact that also lines of the M-group may be calculated from them in the same way as were the L-lines.

If this hypothesis is right we should expect that there are for the heaviest elements seven absorption-edges, five O and probably three P-edges.

Now it may be added that not all the numerical differences between two arbitrary absorption-values correspond to emissionlines. Some of these "calculated" lines for some reason or other do not exist or are too faint to be observed. They belong to what are called "forbidden" transitions.

Physical Interpretation of the X-ray Line-spectra and the Structure of the Atom.—According to the Bohr-Rutherford hypothesis the atoms are built up of a positive nucleus of comparatively small dimensions which is surrounded by a number of electrons. If this general picture of the atom is accepted the X-ray spectra furnishes us with a lot of valuable information regarding the feature of the electronic part of the atom. Then plausible calculations show that the X-ray series of highest frequencies, the K-series, must be connected with the innermost part of the electronic atmosphere of the atom. The other series consequently correspond to successive outer shells of the atom.

In the X-ray absorption-spectra according to this view we find the different energy-levels pictured, which correspond to the energy-output necessary to remove one or other of the electrons of the atom. In consequence we speak of the K-level, the L-levels, etc. of the atom. Correspondingly we speak of different groups of electrons within the electron atmosphere of the atom: the K-shell, the L-shell, etc. Each of these shells may contain several electrons: the K-shell 2, the L-shell 8, the M-shell 18, etc., when they are all completed.

After one electron has—by absorption of energy—been thrown out from its place within the atom its place will soon be filled up by an electron which through the attraction of the positive nucleus falls from some of the outer shells into the empty place. This means a diminishing of the energy of the atom, the superfluous energy being sent out as an X-ray wave. In this way we understand the emission of, for instance, the K-line in the following manner. One of the two electrons belonging to the K-shell has by absorption of energy been removed, its place is taken up an electron from the L-shell, accompanied by emission of the  $K\alpha$ -line. As after this process there is an empty place in the L-shell this may again be filled say by an M-electron with emission of an L-line and so on.

It is seen that this picture of the absorption and emissionprocess is in conformity with the connection between the two kinds of spectra discussed in the preceding paragraph.

As to the structure of the electronic shells of the atoms some general conclusion may be drawn from the empirical knowledge of the X-ray spectra, which, as just mentioned, may be interpreted as coming from the different layers of the electronic atmosphere of the atom.

First the fact that the X-ray spectra of all the elements show a very big resemblance to each other and change from element to element mainly by moving toward higher frequencies must mean that the electronic layers within the atom have the same general

structure for all elements. The increasing of the frequencies is readily understood by the increasing positive charge of the nucleus and the accompanying strengthening of the attractive forces acting on the electrons.

Secondly the appearance of the distinct and widely separated groups: K, L, M... indicates that the electronic atmosphere of the atom consists of distinct layers or shells with decreasing energy-contents beginning with the innermost shell, the K-shell followed by the L-shell, the M-shell and so on.

Thirdly all these shells or groups of electrons (except the K-group) are divided into subgroups as indicated by the existence of more than one absorption-edge or energy-level within every main group.

Further information regarding the structure of the atom is obtained by considering the completeness or rather lack of completeness of the X-ray spectra of the different elements. If one starts with the heaviest element, uranium (with atomic number 92) and proceeds towards the lightest elements it is found that successively and systematically a number of spectral lines (and consequently also absorption-edges) vanish. That means the successive peeling off of electronic shells whereby the number of possible transitions between the groups is reduced. The remaining lines and edges of every atom consequently show directly the number of layers and furnish us with a means of mapping out the electronic structure of the different elements. If we confine ourselves to the inert gases the empirical study of the X-ray spectra suggests the existence of the following shells filled with a number of electrons as given in Table I.

X-ray Spectra and Chemical Constitution .- The most striking difference between the ordinary optical spectra and the X-ray spectra is the fact that the former show a marked resemblance between elements with the same chemical character and change considerably from one group of chemically analogous elements to another whereas in the X-ray spectra no indication of the chemical nature of the elements is to be found. This is readily understood by the picture of the atom and its relation to the spectra which has just been given. From this interpretation the optical spectra arise from the surface of the atom which is also the seat of the chemical bounds, while the X-ray spectra are given off from the inner parts of the electronic atmosphere of the atom. But of course it is to be expected that a small influence may be seen if an atom emitting an X-ray is acted upon by neighbouring atoms. This is a question of the sensitivity or accuracy in the methods of studying the X-ray spectra. By increasing the precision of the measurements it has been possible to detect a number of such effects as just mentioned. It was first found by Bergengren that the K-absorption edge at phosphorus was a little displaced for different modifications of this element. Such an effect was then also found using different compounds of several light elements, especially sulphur, chlorine, etc. It was further found that in some cases the absorption in the neighbourhood of the edge had a complicated structure, which was for the same element dependent on the kind of crystal grating of the compound used for the investigation.

But the line-spectra are also in a certain degree influenced by the chemical bonds as shown by Lundquist, Bäcklin, Ray, etc.

Finally we may in this connection point out the service that the X-ray spectroscopy has rendered as a method of chemical analysis and for the detection of new elements. On the suggestion of Bohr that the element with atomic number 72 may be sought in minerals containing its homologue Zirkon, Coster and Hevesy succeeded in identifying this new element by its X-ray spectrum. Berg, Noddack and Tacke gave convincing evidence of the unknown element 75 by X-ray methods.

Ultra Soft X-rays.—As mentioned in the introduction, the crystal grating method has its limitations in so far as wave-lengths longer than the distance between the atomic layers, say 10 or 20 A.U., may not be selectively reflected. This is clear from the Bragg law (1) which shows that  $\lambda$  cannot be larger than 2d.

Fortunately it was found that ruled gratings when used in nearly grazing incidence gave nice spectra of the radiation with wave-lengths down to the region where the crystals had their

TABLE I

limits. This method was first used by Millikan for the optical spectra and then by Compton and Doan, Siegbahn and others for the study of the ultra soft X-ray spectra.

Of foremost interest is the possibility this opened to make a direct measurement of the atomic distances by comparison with the known grating-constants for the ruled gratings. Subsequently in this way a very exact determination of the value for the fundamental electric unit, the electronic charge was carried out by Bäcklin. It was further possible to extend the different X-ray spectral series into the new wave-length region and to find some lines belonging to higher series N- and O-series. (See also QUANTUM MECHANICS; RADIATION, RAYS; RADIOACTIVITY, NATURAL; SPECTROSCOPY.) (M. SIE.)

SPEE, MAXIMILIAN, COUNT VON (1861-1914), German sailor, was born in Copenhagen on June 22, 1861. He entered the German navy in 1878 and from 1887 to 1888 was Hafenkommandant (commander of the port) in German Cameroon. In 1908 he was made chief of staff of the German North sea command, and at the end of 1912 took over the Far Eastern Squadron. On Nov. 1, 1914, he was engaged by Admiral Cradock off Coronel, on the Chilean coast, and defeated the British squadron. On Dec. 8, 1914, however, he was attacked by Admiral Sturdee's cruiser squadron. The Germans were heavily defeated in the battle that took place. This is usually known as the battle of the Falkland Islands, and in it Spee himself went down with his flagship, the "Scharnhorst." (See Coronex; Falkland Islands, and in it Spee himself went down with his flagship, the "Scharnhorst." (See Coronex; Falkland Islands).

SPEED, JOHN (1552-1629), English historian and cartographer, was the son of a London tailor, and followed his father's trade, being admitted member of the Merchant Taylors company in 1580. He settled in Moorfields, where he built himself a house. He was enabled to devote himself to antiquarian pursuits through the kindness of Sir Fulke Greville, whom Speed calls the "procurer of my present estate," and through his patron's interest he also received a "waiter's room in the custom-house." His important works are: Theatre of the Empire of Great Britaine (1611), a series of 54 maps (with descriptive matter) of different parts of England, which had already appeared separately, and in which he was helped by Christopher Saxton, John Norden and William White, and History of Great Britaine under the Conquests of the Romans . . . to . . . King James (1611). Speed brought some historical skill to bear on the arrangement of his history; in preparing it he received help from Sir Robert Cotton. William Smith, Henry Barkham and Sir Henry Spelman. Although he repeated many of the errors of older chroniclers he added on the whole a substantial contribution of valuable material for the history of his country. He died in London on July 28, 1629.

Other maps of his, beside those in the Theatre, are in the British Museum. Another edition of the Theatre is Theatrem Magnae Britanniae latine, redditum a P. Holland (London, follo, 166). He wrote Genealogies Recorded in Sacred Scriptures (1611), and a similar work, A Cloud of Winessess (1616). These passed through numerous editions, and were frequently prefixed to copies of the Bible. An account of Speed's descendants is to be found in Rev. J. S. Davies's History of Southampton (1883), which was founded on ms. material left by John Speed (1903–1981).

SPEEDOMETERS, instruments for measuring linear speeds—more particularly the speeds of road vehicles—and graduated in miles (or kilometres) per hour. They are driven either from one of the road wheels, or from the transmission, through a flexible shaft and a gear mechanism. Account is taken of the diameter of the road wheel and of the gear ratio between the wheel and the speedometer shaft. Speedometers carry a so-called odometer, which indicates distance.

Main Principles.—The oldest speedometers depend on centrifugal force. A pair of weights is carried on a revolving shaft, in such a manner that they may move out from the axis as in the Watt conical pendulum governor, being restrained by a spring The faster the shaft revolves, the farther the weights will move out from the axis of rotation. An indicator records the speed.

A second principle very extensively used is that of magnetic drag. A cup of sheet aluminium is mounted on a spindle and held in the "zero" position by a spiral spring. A permanent magnet whose lines of force pass through the wall of the cup is rotated inside the latter at a speed proportional to that to be measured. The rotation of the magnet induces currents in the aluminium cup and the reaction between these currents and the magnetism of the magnet produces a drag on the cup, which causes it to turn around its axis against the resistance of the spring, and in proportion to the speed of the magnet. A scale printed on the outside of the cup shows through an opening in the face of the instrument, and the scale reading in line with a mark on the face indicates the speed

A third principle made use of is based on the fact that speed is the quotient of distance by time. Instruments based on this principle comprise an odometer and a clockwork, measuring distance and time respectively, and they effect the operation of division mechanically. A further principle is that of the magneto and voltmeter. A magneto generator has the characteristic that the voltage generated by it varies with the speed at which its armature is driven. Therefore, if a magneto is placed in diving connection with a road wheel and its terminals are connected to a voltmeter whose scale, instead of in volts, is graduated in miles per hour, the combination will serve as a speedometer. This type is particularly adapted for use where it is desirable to take readings at a long distance from the road wheel as the only connected.

tion is by wires. (P. M. H.)

SPEEDWELL, the name applied to the herbaceous species

WOOLLY SPEEDWELL (VERONICA

of the genus Veronica (family Scrophulariaceae); the British forms are herbs with bright blue flowers. The genus Veronica contains about 250 species, temperate, alpine and arctic, many of which are shrubs or trees with handsome spikes of flowers, and are often cultivated. The woody species, rarely known as speedwell, are especially characteristic of the mountains of New Zealand. Some 15 speedwells occur in North America, including several that have been naturalized from the old world. Culver'sroot (Veronica virginica), found (VERONICA across the continent, was formerly much used in medicine.

SPEENHAMLAND SYSTEM, a system of poor relief adopted by the Berkshire magistrates in 1795, by which the wages of labourers were supplemented from the poor-rates up to a certain level, an additional dole being permitted for each child. At a critical moment the Berkshire justices were forced to adopt a desperate remedy, but it was a permicious plan, for it unfairly transferred the burden of wages from the employer to the rate-payer, tencouraged the farmers to pay inadequate wages, and degraded the labourer to the position of a pauper. The system lasted until

the new Poor Law of 1834; it was never in force in Scotland or the north of England.

SPEKE, HUGH (1656-c. 1724), English writer and agitator, was a son of George Speke (d. 1690) of White Lackington, Somerset. Educated at St. John's College, Oxford, Hugh Speke joined the Green Ribbon Club, and in 1683 he was put in prison for asserting that Arthur Capell, earl of Essex, had been murdered by the friends of the duke of York. In prison Speke kept a printing-press, and from this he issued the Address to all the English Protestants in the Present Army, a manifesto written by the Whig divine Samuel Johnson (1649-1703), urging the soldiers to mutiny. In 1687 he was released, and in 1688 he served James II. as a spy in the camp of William of Orange. In December of this year a document, calling upon the Protestants to disarm their Roman Catholic neighbours was freely circulated, and much damage was done to property in London before it was found that it was a forgery. Speke asserted his authorship in his Memoirs (1709), revised as The Secret History of the Happy Revolution in 1688 (1715). Speke died in obscurity before 1725.

SPEKE, JOHN HANNING (1827-1864), English explorer, discoverer of the source of the Nile, was boin on May 4, 1827, at Jordans, Somersetshire. He entered the Indian Army in 1844. He served under Sir Colin Campbell's division in the Punjab. When on furlough Captain Speke explored the Himalayas, and crossed into Tibet. In 1854 he joined Richard Burton in Somaliland, as narrated in What led to the Discovery of the Source of the Nile (London, 1864). In April 1854 Speke was wounded by Somalis. Invalided home, he volunteered for the Crimea and

served with a regiment of Turks.

In 1856 Speke joined Burton in exploration of the African lakes, especially Nyassa. The route to Nyassa was closed by the Arabs, and the travellers left Zanzibar in June 1857 by a more northerly route. They learnt from an Arab trader that further inland were three great lakes-and Speke assumed that the most northerly would be the source of the Nile. In January 1858 the travellers reached Lake Tanganyika. By June they were back at Kazé, and here Speke induced his chief, who was ill, to allow him to attempt to reach the northern lake. Marching north for 25 days, on July 30 Speke reached a creek, along which he travelled till, on Aug. 3, he saw it open up into the waters of a lake extending northward to the horizon. He no longer doubted that this lake-the Victoria Nyanza-was the source of the Nile. Returning to Kazé (Aug. 25) he made known his discovery to Burton, who did not believe Speke's theories.

Speke had the support of Sir Roderick Murchison, president of the Royal Geographical Society, under whose direction a new expedition was fitted out. Of this expedition Speke had the command, his only European companion being Captain (afterwards Colonel) J. A. Grant (q.v.). The expedition, over 200 men all told, started from Zanzibar in Oct. 1860 and reached Kazé on Jan. 24, 1861. The Victoria Nyanza was again reached, at its south-west corner, in Oct. 1861. Following the western shores of the lake Speke crossed the Kagera Jan. 16, 1862, and arrived at the capital of Uganda on Feb. 19 following. Here he was detained by the king Mtesa, for some months, but at last prevailed on the chief to furnish him with guides, and on July 28 Speke stood where the Nile issued from the lake. The travellers were not permitted to visit another large lake (the Albert Nyanza) of whose existence and connection with the Nile they learned. As far as possible Speke and Grant followed the course of the Nile, and on Dec. 3 came in touch with the outside world once more. On Feb. 15, 1863, they arrived at Gondokoro. At Gondokoro they met Sir Samuel (then Mr.) Baker, generously giving him the information which enabled him to discover the Albert Nyanza.

In the same year (1863) Speke published his Journal of the Discovery of the Source of the Nile, a work written in a frank, attractive style. His conclusions were disputed by Burton and McQueen in The Nile Basin (1864), it being argued in this work that Tanganyika was the true Nile source. Speke was to discuss the question with Burton at the geographical section of the British Association at Bath on Sept. 16, but he accidentally shot

himself while out after partridge on Sept. 15.

See, besides the works mentioned, Sir R. F. Burton, The Lake see, besides the works mentioned, i. H. F. Button, Inc Lake Regions of Central Africa (1860; J. A. Grant, A Walk across Africa (1864); T. D. Murray and A. S. White, Sir Samuel Baker: a Memoir (1895); The Times (Sept. 17 and 19, 1864); Sir H. H. Johnston, The Nile Quez' (n.d. [1903]).

SPELL, a word of Teutonic origin meaning something "spoken." In general terms, the belief underlying the use of spells is that the wish that they embody will be fulfilled, regardless of its goodness or badness, so long as the formula has been correctly pronounced. Broadly speaking, then, spell and prayer, like

magic and religion to which they severally belong, can be dis-

tinguished by the nature of the intended purpose.

Ritual is to be seen in relation to its moral context as a whole. For instance, the judicial oath may have lost some of its special significance as a religious act of binding force, but, taken in connection with the solemn endeavour, of which it forms a part, to administer justice in the light of the truth, its validity can hardly be said to have been affected. Or, again, charges of formalism as regards the details of religious worship are recklessly bandled about, when the spirit and not the letter of the observance should alone be regarded as relevant to the issue Next, as regards the criterion of intelligibility, we must make sure in using it that we are not making our own ignorance the measure of the intrinsic value of the rite alleged to be without meaning Just as any foreign tongue is gibberish to the unlearned, so we may be deaf to the most eloquent symbolism if we have not a key to the sense.

To take an example from Australia, if members of the witchetty grub totem desire to secure a harvest of these grubs for the benefit of the community, they repair in procession to certain stones that remind them by their shape of witchetty grubs and rub their stomachs with these stones, thus indicating the precise destination to which the symbolized delicacies are meant to find their way. Moreover, this pantomime is reinforced by oral means in the solemn declaration, "We have eaten much food"; where, let the perfect tense be noted, as if for the man

of faith the thing were as good as done.

The chief deity of the Masai goes by the name that simply means "The Rain"; and the simplest of their rites consists in crying out "Rain! Rain!" in chorus (see PRAYER). Here the question whether this is prayer or spell ought not to turn on the degree of personality attaching to the god, and still less on a grammatical point such as the possible use of the imperative mood. Surely the religious character of the whole proceeding is sufficiently established by the fact that "The Rain" is for the Masai, the reputed giver of all good things.

In primitive rite the verbal formula tends to be accessory to the dramatic part of the procedure. Sometimes it is but descriptive of the action, "We are doing so and so," though sometimes the purpose is added, "We are doing so and so, that so and so may happen." Thus the efficacy of the rite, words and all, is apt to seem self-contained. The rite has man : (q.v.), which is almost to say "It works, I know not why" in one pregnant word. Correspondingly, it becomes a perilous instrument for the ordinary man to handle, and its use is reserved for the man with manathe expert who is strong enough to wrestle with mysteries. Now to be vested with esoteric attributes in one's own eyes no less than in the eyes of the rest bears hard on the weakness of the flesh. True, the wonder-worker may be ready to admit that his mana possesses him rather than he it. An Australian medicineman, for instance, who had given way to European strong drink, became convinced that his healing power had left him and in a spirit of befitting humility retired from practice. Or, again, we have the Malay wizard whose spell explicitly announces that some power greater than himself is working through him: "It is not I that am burying him (in the form of a waxen image), it is Gabriel who is burying him."

In Melanesia and elsewhere a man owns a ritual and charms so completely that he can bequeath them to a son. Nay, he can even sell them in the open market, and in such a case we expressly learn that the oral part of the rite-the muttered spell-is what the money is paid for, since it is what the owner can most easily hide and so keep to himself. At this point the spell has clearly become a non-moral thing, a mere trade secret. It will degenerate still further into abracadabra. The folklorist is constantly coming across oral survivals in the mouths of peasants that once were medical recipes or even prayers couched in Latin. Afterwards, when reduced to mere rigmarole, these have been treasured by the unlettered for the sake of the sheer mystery lurking in the unfamiliar sounds.

SPELLO (Hispellum, q v.), a town of Umbria, 1,030 ft. above sea-level. Pop. (1936), 2,731 (town); 6,578 (commune). S. Maria Maggiore contains some of Pinturicchio's finest frescoes (1501), "The Annunciation," "The Adoration" and "Christ in the Temple."

SPELMAN, SIR HENRY (c. 1564-1641), English antiquary, was the eldest son of Henry Spelman, of Congham, Norfolk, and the grandson of Sir John Spelman (c. 1495-1544), judge of the king's bench He was educated at Walsingham School and Trinity college, Cambridge. With Sir Robert Cotton and William Camden, he belonged to the Society of Antiquaries, which declined, and Spelman's efforts to revive it in 1614 were frustrated by James I. Spelman proposed to write a work on the foundations of English law, based on early charters and records; as a preliminary to this task he began to compile a glossary, the first volume of which, Archaeologus in modum glossarii, was published at his own expense in 1626. He continued to work at the subject until 1638. A second volume, Glossarium archaiologicum (1664) appeared after his death. His Codex legum veterum statutorum regni Angliae, quae ab ingressu Gulielmi I usque ad annum nonum Henry III. edita sunt was published by David Wilkins in his Leges anglo-saxonicae (1721). Spelman's most important work, Concilia, decreta, leges, constitutiones in re ecclesiarum orbis britannici (2 vols., 1636-64), is an attempt to place English church history on a basis of genuine documents. Spelman took a prominent part in public business until his death (Oct. 1641). He was buried in Westminster Abbey.

SPENBOROUGH, an urban district in the West Riding of Yorkshire, England, 5 mi. S.S.E. of Bradford on the L.M.S.R. Pop. (est. 1938) 36,420. Area 12,9 sq.mi. It is a busy manufacturing district situated in the Spen Valley. The chief industries are the manufacture of woollen goods, machinery and chemicals. and coal mining. The urban district was formed in 1915 and combined the three former urban district was formed in 1915 and combined the three former urban districts of Cleckheaton, Gomersal and Liversedge. In 1937 its area was enlarged by the addition of the urban districts of Birkenshaw and Hunsworth and the rural district of Hartshead, besides other land.

SPENCER, ANNA GARLIN (1851-1931), U.S. clergywoman, was born in Attleboro, Mass., on April 17. She early discovered the power and magnetism of her speaking voice and while on the staff of the Providence Journal (1868-78), lectured on social problems. After her marriage to the Rev. William H. Spencer (Unitarian) in 1878, her husband encouraged her to preach in liberal pulpits. In 1891 she was ordained as minister of the Bell Street chapel (Independent), Providence, R.I., where she officiated for 14 years. From the beginning interested in women's rights, Mrs. Spencer participated actively in the Rhode Island Women's Suffrage association, and in the national women's rights conventions, where she emphasized the contributions women could make to society, the theme of her book, Woman's Share in Social Culture (1913). Her own contributions were of wide scope in local and national charities and reforms. To list a few, she was first chairman of the Women's Section of the World Peace conference organized in 1907, associate director and staff lecturer at the New York School of Philanthropy (1903-13), associate leader of the New York Society for Ethical Culture (1903-09), director of the American Ethical Union's Summer School of Ethics (1908-11), Professor of Sociology and Ethics at the Meadville (Pa.) Theological school (1913-18), and lecturer at the University of Chicago (1918) and thereafter occasionally at Teacher's college, Columbia university, Besides many articles and pamphlets, she wrote several books, among them the History of

the Bell Street Chapel Movement (1903) and The Family and its Members (1923). While director of the Family Relations division of the American Social Hygiene association (the moral education movement was one of her lifelong interests), she died on Feb. 12, 1931 (L A G)

SPENCER, HERBERT (1820-1903), English philosopher, was born at Derby on April 27, 1820. His father, William George Spencer, was a schoolmaster, and his parents' religious convictions familiarized him with the doctrines of the Methodists and Quakers. He declined an offer from his uncle, the Rev. Thomas Spencer, to send him to Cambridge, and so was practically self-taught During 1837-46 he was employed as an engineer on the London and Birmingham railway; in 1848-53 as sub-editor of the Economist. From about this time to 1860 he contributed numerous articles to the Westminster Review, which contain the first sketches of his philosophic doctrines. He also published two larger works, Social Statics in 1850, and Principles of Psychology in 1855. In 1860 he sent out the syllabus of his Synthetic Philosophy in ten volumes, which he completed in 1896 with the Principles of Sociology. He died on Dec. 8, 1903.

Spencer's significance in the history of English thought depends on his position as the philosopher of the great scientific movement of the second half of the 19th century, and on his friendship with men like Darwin, G. H. Lewes, and Huxley. He trees to express in a general formula the belief in progress which pervaded his age, and to erect it into the supreme law of the universe But to the specialists in sciences which were advancing rapidly to results which often transformed their initial assumptions, Spencer has often appeared too much of a philosopher and defective in specialist knowledge; to the technical philosophers he has not seemed philosophic enough.

Spencer claims, with some reason, that he was always an evolutionist. But his notions of what "evolution" is developed gradually. At first he seems to have meant only the belief that progress is real, and that the existing order of nature is the result of a gradual process. In Social Statics (1850) he still regards the process teleologically, and argues after the fashion of Paley that "the greatest happiness is the purpose of creation" (ch. iii § 1). In The Development Hypothesis (1852) he objects strongly to the incredibility of the special creation of the myriad forms of life, without, however, suggesting how development has been effected. In Progress, its Law and Cause (1857) he adopted Von Baer's law, that the development of the individual proceeds from the homogeneous to the heterogeneous. This is at once connected with the nebular hypothesis, and subsequently "deduced" from the ultimate law of the "persistence of force," and finally supplemented by a counter-process of dissolution, all of which appears to Spencer only as "the addition of Von Baer's law to a number of ideas that were in harmony with it." Spencer welcomed Darwin's Origin of Species (1859) and enriched its doctrines with the phrase "survival of the fittest"; but he did not give up the (Lamarckian) belief in the hereditary transmission of the modifications of organisms by the exercise of function.

Of his First Principles (1862) the first part shows that while ultimate metaphysical questions are insoluble they compel to a recognition of an inscrutable Power behind phenomena which is called the Unknowable; the second part is devoted to the formulation of the Law of Evolution. In the first part Spencer's argument rests on Mansel's Limits of Religious Thought and Hamilton's "philosophy of the conditioned" (and so ultimately on Kant), and tries to show that in scientific and religious thought the ultimate terms are "inconceivable" (not by him distinguished from "unimaginable"). In science, the more we know the more extensive "the contact with surrounding nescience." In religion the vital and constant element is the sense of mystery. This is illustrated by the difficulties inherent in the conception of Cause, Space, Time, Matter, Motion, the Infinite, and the Absolute, and by the "relativity of knowledge," which precludes knowledge of the Unknowable, since "all thinking is relationing." Yet of the Unknowable we may have an "indefinite knowledge," positive, though vague. Hence both science and religion must recognize as the "most certain of all facts that the Power which the Universe manifests to us is utterly inscrutable." In the edition of his First Principles, published in 1900, he adds a "postscript" which shows some consciousness of the contradiction involved in his knowledge of the Unknowable, and finally contends that his account of the Knowable in part ii. will stand even if part i. be rejected. But, in reality, a really inscrutable Unknowable would destroy all confidence in the order of nature and render all knowledge precarious.

In part ii. Spencer recognizes successively likenesses and unlikenesses among phenomena (the effects of the Unknowable), which are segregated into manifestations, vivid (object, non-ego) or faint (subject, ego), and then into space and time, matter and motion and force, of which the last is symbolized by our experience of resistance, and is that out of which our ideas of matter and motion are built. Hence the Persistence of Force is the ultimate basis of knowledge. From it Spencer deduces the indestructibility of matter and energy, the equivalence and transformation of forces, the necessity of a rhythm, of Evolution (i.e., integration of matter with concomitant dissipation of motion) and Dissolution, and finally the statement of the Law of Evolution as "an integration of matter and concomitant dissipation of motion, during which the matter passes from an indefinite incoherent homogeneity to a definite coherent heterogeneity, and during which the retained motion undergoes a parallel transformation." This process of evolution is due to "the instability of the homogeneous," the "multiplication of effects" and their "segregation," continuing until it ceases in complete "equilibration." Sooner or later, however, the reverse process of Dissolution, with its absorption of motion and disintegration of matter must prevail, and these oscillations of the cosmic process will continue without end. It appears, therefore, that Spencer ultimately describes the Knowable in terms of the mechanical conceptions of matter and motion, and this gives a materialistic colouring to his philosophy.

In the Principles of Biology (1864) the chief points are the definition of life as the continuous adjustment of internal to external relations, and the consequent emphasis on the need of adapting the organism to its environment. This does not sufficiently recognize that the higher organisms largely adjust external to internal relations and adapt their environment to their needs. His universal process of Evolution seems to give Spencer a criterion of "higher" and "lower" "progression" and "degeneration," independent of the accidents of actual history. The higher (at least in times of "evolution") is the more complex, whether it invariably survives or not. On the other hand, he advances too easily from the maxim that function is prior to structure to the conclusion that the results of use and disuse are immediately incarnate in structural adaptations capable of hereditary transmission, an inference that has involved him in controversy with Weismann's school.

In his Principles of Psychology (1870-72) Spencer advocates the genetic explanation of the phenomena of the adult human mind by reference to its infant and animal ancestry. On the fundamental question, however, of the psychophysical connection and the derivation of mind from matter, his utterances are neither clear nor consistent. On the one hand, his whole formulation of Evolution in mechanical terms urges him to compose the mind out of homogeneous units of consciousness (or "feeling") "similar in nature to those which we know as nervous shocks; each of which is the correlative of a rhythmical motion of a material unit or group of such units" (§ 62); on the other hand, he is ready to amend nervous into psychical shocks, which is no doubt what he ought to have meant but could not say without ruining the illusory bridge between the psychical and the physiological which is suggested in the phrase "nervous shock." And he admits (§ 63) that if we were compelled to choose between translating mental phenomena into physical and its converse, the latter would be preferable. But he finally leaves the relation between the unknowable "substance of Mind" and the unknowable "substance of Matter" to the Unknowable. To the theory of knowledge Spencer contributes a "transfigured realism," to mediate between realism and idealism, and the doctrine that "necessary truths," acquired in experience and congenitally transmitted, are a priori to the

individual, though a posteriori to the race, to mediate between empiricism and apriorism.

In the Principles of Sociology (1877–96) Spencer's most influential ideas have been that of the social organism, of the origination of religion out of the worship of ancestral ghosts, of the natural antagonism between nutrition and reproduction, industrialism and warfare. Politically, Spencer was an individualist of an extreme laises faire type, and it is in his political attitude that the consequences of his pre-Darwinian conception of Evolution are most manifest. But for this, he would hardly have established so absolute an antithesis between industrial and military competition, and would have been readier to see that the law of the struggle for existence, just because it is universal and equally (though differently) operative in every form of society, cannot be appealed to for guidance in deciding between the merits of an industrial or military and of an individualist or socialist society.

In the Principles of Ethics Spencer, though relying on the intrinsic consequences of actions for the guidance of conduct, conceives the ethical end in a manner intermediate between the hedonist and the evolutionist. The transition from the evolutionist criterion of survival to the criterion of happiness is effected by means of the psychological argument that pleasure promotes function and that living beings must, upon pain of extinction, take pleasure in actions conducive to their survival. Conduct being the adjustment of acts to ends, and good conduct that which is conducive to the preservation of a pleasurable life in a society so adjusted that each attains his happiness without impeding that of others, life is valuable only if it conduces to happiness. On the other hand, life must in the long run so conduce because a constant process of adjustment is going on which is bound to lead to a complete adjustment which will be perfect happiness. Spencer concludes that the sense of duty must diminish as moralization increases In this reasoning Spencer overlooks the possibility of an expansion of the ethical environment. If this is as rapid as the rate of adaptation, there will be no actual growth of adaptation and so no moral progress. Complete adaptation to an infinitely receding ideal is impossible, but Spencer considers that he can both anticipate such a state, and lay down the rules obtaining in it, which will constitute the code of "Absolute Ethics." He conceives it as a state of social harmony so complete that even the antagonism between altruism and egoism will have been overcome; everyone will derive egoistic pleasure from doing such altruistic acts as may still be needed. Originally the socially salutary action was in the main that which was enjoined on the individual by his political and religious superiors and by social sentiment; it was also in the main that to which his higher, more complex and re-representative feelings prompted. Hence the fear with which the political, religious and social controls were regarded came to be associated also with the specifically moral control of lower by higher feelings, and engendered by coercive element in the feeling of obligation. Its authoritativeness depends on the intrinsic salutariness of self-control, and must cease with the resistance of the lower feelings. Hence Spencer concludes that the sense of duty must diminish as moralization increases. In the preface to the last part of his Ethics (1893) Spencer regrets that the Doctrine of Evolution has not furnished guidance to the extent he had hoped," but his contributions to ethics are not unlikely to be the most permanently valuable part of his philosophy.

losophy.

After completing his system (1806) Spencer continued to revise it, and brought out new editions of the Biology (1808-90) and First Principles (1900). The dates of his chief works are as follows: 1822, Letters to the Nonconformist, "The Proper Sphere of Government"; 1850, Social Statistics; 1822, The Theory of Population (6, part vi. of Biology): "The Development Hypothesis" (in Essays, vol. i.) 1833; The Universal Potulate (6, Psychology, part vii.); 1843, "the Genesis of Science" (in Essays, vol. ii.); 1855, Principles of Psychology (2, 10.); 1857, Progress, its Law and Cause (Essays, vol. i), 1835, Essays (containing most of his contributions to the Westminster Review, 1865, vol. i; 1885, vol. iii.); 1854, Education: Intellectual, Moral, Physical; 1666, Errt Principles (and ed., 1867; 6th, 1906); 1864-67, Principles of Psychology (and ed., in a vol.); 1873, The Study of Sociology; 1876, vol. i, The Principles of Sociology; vol. ii., Coremonial Institutions, 1887, Vol. ii. The Principles of Sociology; vol. ii., Coremonial Institutions, 1887, Vol. iii. Ecologic 1879, The Dala of iii. Ecologic 1879, The Dala of

Ethics (part i of Principles of Ethics in 2 vols.; part iv., Justice, 1891; parts it, and itt., Inductions of Ethics and Ethics of Individual Life, 1892; parts v. and vi., Negative and Positive Beneficence, 1893). 1884, Man versus the State. 1886, Factors of Organic Evolution. 1893, Inadequacy of Natural Selection. 1894, A Rejoinder to Professor Weismann and Weismannism once more. 1897, Fragments. 1902, Facts and Comments. An Autobiography in 2 vols. appeared posthumously in 1904. For a useful summary of his chief doctrines by Spencer himself see his preface to Collins's Epitome of the Synthetic Philosophy: see also I. A. Thompson, H. Spencer (1906); W. H. Hudson, H. Spencer (1908).

SPENCER, JOHN CHARLES SPENCER, 3RD EARL (1782-1845), English statesman, better known by the courtesy title of Lord Althorp, which he bore during his father's lifetime, was the son of George John, 2nd Earl (1758-1834), who served in the ministries of Pitt, Fox and Grenville, and was first lord of the admiralty from 1794-1801. John Charles was born at Spencer House. London, on May 30, 1782, and was educated at Trinity college, Cambridge. He represented Okehampton (1804), St. Albans (1806) and Northamptonshire (1806). When Lord Grey's administration was formed at the close of 1830 the chancellorship of the exchequer combined with the leadership of the House of Commons was entrusted to Lord Althorp. The budget was a failure, but this misfortune was soon forgotten in the struggles over the Reform bill, in the preparation and success of which Lord Althorp played an important part.

The death of the 2nd Earl Spencer in Nov. 1834, called his son to the upper house and was the occasion of Melbourne's dismissal by King William IV. He was the first president of the Royal Agricultural Society (founded 1838), and a notable cattle-breeder. He died at Wiseton on Oct. 1, 1845.

See Sir Denis Le Marchant, Memoir (1876); W. Bagehot, Biographical Studies (1881); E. J. Myers, Lord Althorp (1890).

SPENCER, JOHN POYNTZ SPENCER, 5th EARL (1835-1910), English statesman, was the son of the 4th Earl and his first wife. Born on Oct. 27, 1835, and educated at Harrow and Trinity college, Cambridge, he was a member of parliament for a few months before he succeeded to the earldom in Dec. 1857. His long career as a Liberal politician dates from his acceptance of the office of lord-lieutenant of Ireland under Gladstone in 1868, a post which he retained until 1874. When the Liberals returned to power in 1880 he was appointed lord president of the council, but in 1882 he entered upon a second term of office as lord-lieutenant of Ireland. In the Liberal administration of 1886 he was lord-president of the council, and from 1892 to 1895 he was first lord of the admiralty. From 1902 to 1905 he was the Liberal leader in the House of Lords, and early in 1905, was discussed as a possible Liberal prime minister. He died on Aug. 13, 1910. The fine library, collected at Althorp by the 2nd earl, was sold by him for £250,000 to Mrs. Rylands, the widow of a Manchester merchant, who presented it to that city.

SPENCER, a town of Worcester county, Massachusetts, U.S.A. Pop. (1950) 7,047. Spencer was settled in 1721 and incorporated in 1753. One of its houses was the birthplace of three inventors: William Howe, Tyler Howe and Elias Howe, Jr., who invented respectively the "Howe truss" bridge, the spring bed and the sewing machine

SPENDER, JOHN ALFRED (1862-1942), British journalist, was born at Bath, the son of a doctor, and educated at Bath college, and at Balliol college, Oxford. Adopting the career of a journalist, he was editor of the Eastern Morning News, Hull, from 1886 to 1890 and then was with the Pall Mall Gazette in London. When the Westminster Gazette was established in 1893, he became an assistant editor and from 1896 to 1922 was its editor, leaving just after it became a morning paper. As editor of the Westminster Spender won general respect, not only as a brilliant writer but as the possessor of an exceptionally fair and balanced mind. He held a high place in the councils of the Liberal party and his services to the state included membership of the royal commission on divorce and of the Milner Mission to Egypt. A slight volume, The Comments of Bagshot (1907), revealed Spender at his best. Other works include The Indian Scene (1912); The Foundations of British Policy (1917); Life, Journalism, and Politics (2 vols. 1927); A Short History of Our Times (1934); Men and Things (1937). He died on June 21, 1942 SPENER, PHILIPP JAKOB (1635–1705), German the-ologian, was born on Jan. 13, 1635, at Rappoltsweller in Upper Alsace. He won his degree of master at Strasbourg (1653) by a disputation against the philosophy of Hobbes. In 1666, he was chief pastor in the Lutheran Church at Frankfort-on-Main. Here he published his two chief works, Pia desideria (1675) and Allgemeine Gottesgelehrtheit (1680), and began that form of pastoral work which resulted in the movement called Pictism. In 1686 he accepted the invitation to the first court chaplaincy at Dresden. But the elector John George III. was offended by his chaplain's candour. Spener refused to resign his post, and the Saxon government hesitated to dismiss him. The difficulty was solved by his promotion (1691) to the rectorship of St. Nicholas in Berlin with the title of "Konsistorialrat." The university of Halle was founded under his influence in 1694. Spener was exposed to the abuse of orthodox Lutheran theologians. In 1695 the theological faculty of Wittenberg formally laid to his charge 264 errors. He died on Feb. 5, 1705. His last important work was Theologische Bedenken (4 vols., 1700-02), to which was added after his death Letzte theologische Bedenken, with a biography of Spener by C. H. von Canstein (1711). Though "the father of Pietism," the extravagances of the movement cannot be ascribed to him personally.

Spener was a voluminous writer. The list of his published works comprises 7 vols. folio, 63 quarto, 7 octavo, 46 duodecimo; a new edition of his chief writings was published by P. Grünberg in 1889, See W. Hossbach, Philipp Jabob Spener und seine Zeit (1828, 31d ed., 1861); A. Ritschl, Geschichte des Pielismus, ii. (1884); E. Sachsse, Urrprung und Wesen des Pielismus (1884); P. Grünberg, P. J. Spener (2) vols (2802-1006). (3 vols., 1893-1906).

SPENGLER, OSWALD (1880-1936), German philosopher, was born at Blankenburg in the Harz on May 29, 1880. He studied mathematics and natural history, with history and art. This rare combination is the foundation of the peculiar character of Spengler's work, in which unexpected parallels between scientific truths of physics and mathematics and the artistic and other cultural achievements of an epoch of history are drawn. He completed in 1914 the first version of Der Untergang des Abendlandes (1918, rev. ed. 1922; Eng. trans. The Decline of the West, by C. F. Atkinson).

Other works of Spengler, chiefly concerned with contemporary political problems are: Preussentum und Sozialismus (1920); Pessimismus (1921); Politische Pflichten der deutschen Jugend (1924); Neubau des deutschen Renches (1924). See M. Schroeter, Der Streit um Spengler, etc. (1922).

SPENSER, EDMUND (?1552-1599), "the prince of poets in his time," was born in London-Oldys says, in East Smithfield -probably in 1552, possibly in 1549. (The date depends on whether Sonnet 60, written when Spenser was 41, belongs to 1593 or to 1590: v. infra.) His mother's name, he tells us, was Elizabeth: his father has been conjecturally identified with John Spenser, a journeyman cloth-maker. Later, the poet claimed kindred with the Spencers of Althorpe in Northamptonshire, and had his claim allowed; but the poverty of his home is shown by the grants made to him out of the Nowell bequest as a poor scholar of Merchant Taylors' school. There, under the great Mulcaster, he laid the foundations of his wide, if inexact, scholarship; best of all, he learned from Mulcaster to "worship the English," and to believe it as capable of great poetry as any language. He was still at school when, in 1569, he supplied some verse translations from Marot and du Bellay to Van der Noodt's Theatre of Worldlings. Van der Noodt, it is true, took the credit of these verses to himself: but they were included, with some alterations, in the Complaints volume of 1591 (v. infra), and we need not doubt that they are Spenser's. The rhymed stanzas after Marot at least bear his mark: the blank-verse renderings from du Bellay are inferior, and were considerably altered and tagged with rhymes for the re-issue of 1591.

In this same year he entered Pembroke hall, Cambridge, as a sizar, matriculating on May 20. He remained at Cambridge for seven years, as was then not unusual, proceeding B.A. in 1572 and commencing M.A. in 1576. His health was poor; but he read

SPENSER 205

widely, especially in philosophy and rhetoric, studying Italian as well as Latin, Greek and French, and training himself for poetry. His studies profited from the friendship of Gabriel Harvey, a fellow of his college, a conceited pedant, but a real scholar, and sincerely attached to Spenser, though his friendship may not always have been quite disinterested nor his literary advice wase. Literature, however, stirred the mind of Cambridge less than theology. In the ecclesiastical controversy with which the university had seethed ever since Cartwright's brief tenure of the chair of divinity (1569–70), Spenser took the Puritan side. But he was neither sectary nor ascetic. He had a hatred of popery (inflamed by the Bartholomew massacre) and contempt for the hirelings who "for their bellies' sake" had climbed into the Anglican fold

who "for their bellies' sake" had climbed into the Anglican fold. What he did on leaving Cambridge is still a mystery. He had missed his fellowship, and must look about him for a profession or a patron. The view that he went to live with relatives in Lancashire, though buttressed by appeals to family tradition and to the language and scenery of the Calender, rests at bottom on

no ascertained fact.

But in the "North-parts" (Drayton brings Rosalind to the Cotswolds; Aubrey says that she was related to Sir Erasmus Darwin's lady, who was a Wilkes of Hodnell in Warwickshire), Spenser fell in love with the Rosalind of the Shepheardes Calender, of whom again we can say only that she was a lady of higher rank than his, who enjoyed, but did not reward, her young poet's devotion. In 1577 we seem to get a glimpse of Spenser in an unexpected quarter. In the View of the Present State of Ireland Irenaeus tells how he witnessed the execution of Murrogh O'Brien, which took place at Limerick in July, 1577. In the rest of that dialogue Irenaeus represents Spenser himself, and it is natural though not inevitable to conclude that he does so in this place also. But no other evidence has been found for this visit; Phillips's statement that Spenser was secretary to Sir Henry Sidney may be discounted, since he has probably confused Sidney with Grey. Yet Irenaeus's account of this hideous incident reads like the words of an eye-witness, and the visit, if it occurred, would point to a connection with the Sidney-Leicester circle earlier than 1579.

After this we are on firmer ground. We know that in 1578 Spenser was secretary to John Young, bishop of Rochester, who had been master of Pembroke hall while Spenser was a student. The bishop of Rochester (Episcopus Roffensis) is the Roffyn of the Shepheardes Calender: the fable of Roffyn's dog and the wolf may glance at the old Roman Catholic bishop, Thomas Watson, who was committed to Young's custody in Feb. 1579. Much of the Shepheardes Calender was apparently written at Rochester, where also Spenser first conceived the idea of the wedding of Thames and Medway. If Spenser at this time thought of entering the Church, he changed his mind on a nearer view of its condition, for by Easter 1579 he was in Westminster, sharing rooms with Harvey and holding "long conference" with him. There was a third party to their discussions, one "E.K.," to be identified probably with Edward Kirke, once a fellow-sizar of Spenser's at Pembroke. The notion that E.K. is a mask for Spenser himself has been disproved by Dr. Herford. It is not unlikely, indeed, that the "Mistress Kerke" in Westminster, who took charge of letters for Spenser in October of this year, was E.K.'s mother, and that all three were living in her house. Among other things they discussed Spenser's début as an author. He had several pieces ready or nearly ready-Dreams, Legends, Court of Cupid, Pageants, The English Poet (in prose), and the Shepheardes Calender. It was decided to bring out the last, and to bring it out in classical style with introduction, notes and glossary by E.K., even as Muretus edited the first book of Ronsard's Amours. E.K. wrote the introduction forthwith-it is dated from London, April 10, 1579-and got to work on the notes.

Harvey's Letter-book gives us an amusing picture of Spenser that summer. He is reading some law, evidently with an eye to diplomatic or administrative work; he has blossomed into a courtier and a gallant, bearded and moustachioed, Italianate, Frenchified. At what date, and in what sense, he entered Leicester's service we do not know precisely. At all events on Oct. 5 he writes from Leicester house to tell Harvey that he expects to go

abroad in a week, "most what" at Leicester's charges—the "most what" shows that he was not entirely dependent on Leicester's bounty—and that "gentle Mr. Sidney" has proposed that they two should correspond. The tour apparently never took place, for his next letter of ten days later says no word about it, but is all concerned with quantitative verse and with doubts about the publication of his Slumbers. He has been to Court and expects to go again; Sidney and Dyer have him "in some use of familiarity." The Shepheardes Calender was licensed on Dec. 5, and published anonymously; the dedication to Sidney is by "Immerito."

The Shepheardes Calender.—The Calender consists of 12 pastoral ecloques in the artificial style of Virgil, Mantuan, Sanazzaro and Marot, which admits real persons and current events in a pastoral guise From all these precursors Spenser borrowed ostentatiously, above all from Marot, whom E. K. nevertheless belittles, perhaps because the Pléiade had eclipsed him. Derivative and conventional as it is, the Calender made an epoch in English literary history, not so much by naturalising pastoralism as by showing (under cover of the pastoral convention) what English could do in many kinds and metres. The couplets of the satires and fables are intentionally rude, and the rhymeless sestina is mere virtuosity; but the elegiac stanzas of the complaints recaptured the metrical secret of Chaucer, and the lyric staves of the paean and the dirge extended the range of English song. In all these measures he made free use of alliteration, dear to English ears, though abused by his contemporaries and frowned on by the classicists. For his reform of poetic diction Spenser had before him the example and precepts of the Pléiade. Like them, he sought to embellish the beggarly vocabulary of contemporary verse, partly by foreign loan-words, but mainly by drawing on native sources, by archaisms, pseudo-archaisms and dialect words. He was in search of a vocabulary fit for the heroical poem that he already contemplated. But the new poet had to care not only for words but for the order of his words and the structure and juncture of his sentences. Here Spenser scored his greatest success, eschewing obscurity and looseness, and giving his syntax a movement, too copious perhaps, but admirably fluent, in lucid, easy yet well-knit sentences. Syntactically, Spenser is one of the simplest of poets.

The Shepheardes Calender may not have fulfilled all Spenser's hopes, but it went into a second edition in 1581. Sidney praised it judiciously, or judicially, but durst not approve its rustic diction. However, Spenser had many other arrows in his quiver. In April 1580 he is full of projects for the immediate publication of his Dying Pelican and Dreams; his Latin Stemmata Dudleiana will need "more advisement" before it can be "sent abroade," but the quantitative Epithalamion Thamesis shall be "shortly set forth." Under the influence of Sidney, Dyer and Drant, he had come for the moment to take quantitative verse more seriously. But he is more eager to proceed with the Faerie Queene, of which he sent Harvey specimens. Harvey thought little of them, preferring the (lost) Nine Comedies in the manner of Ariosto. Moreover, the poet is in love again, this time with better hopes. Harvey's compliments to Mea Domina Immerito, Mea Bellissima Collina Clouta, taken with an obscure passage in Daphnaida (11. 64-66), which reads like consolation tendered by one widower to another, have led some scholars to believe that Spenser married this "second Rosalind." But there is no other evidence for the marriage, nor is the lady ever heard of again. These letters of April 1580 give no hint of any friction with Leicester. But now Spenser seems to have made a false step. The queen had dallied for years with the project of marrying the duke of Alençon. In Jan. 1579 his agent Simier came to England and Alençon himself paid a flying visit in August to press his suit in person. He was ugly, dwarfish and half her age, but the queen smiled on him, called him her "grenouille" and Simier her "petit singe." The Puritans took alarm. Sidney remonstrated in such plain terms that the queen forbade him the Court. He retired to Wilton to write his Arcadia, and Spenser probably never saw him again. This was in Jan. 1580.

It was at this juncture apparently that Spenser drew his pen. He had begun a fabliau of an ape and a fox, satirising the Parson Trullibers and other humbugs of the day. Now, catching at Elizabeth's trick of animal nick-names, he brought his ape and fox to a court of beasts. The ape becomes Alençon-Simier, the fox is Burghley, who was believed to favour the marriage. Their misrule when they have stolen the lion's skin foreshadows the fate of England under a French king-consort. But Spenser misjudged the situation. Leicester had concluded that the wind stood fair for France, and trimmed his sails accordingly. Spenser was snubbed, and the satire, which was circulating in manuscript as Mother Hubberds Tale, was called in, but not before it had come to Burghley's ears. The tale of Spenser's discomfiture is told in Virgils Guat, killed by the man whose life it had saved. Such is the most plausible explanation of this obscure episode. At all events, abandoning all his projects of publication, Spenser accepted a secretaryship to Lord Grey of Wilton, the newly appointed Lord Deputy of Ireland.

In Ireland.—Grey landed in Dublin in Aug. 1580 and set himself at once to the task of suppressing Desmond's rebellion. He was a stern Puritan, to whom the pope was Anti-christ and the Papist rebels were traitors at once to God and their queen. Spenser soon had proof of his quality. A band of Spanish and Italian filibusters had landed in Kerry to support the Munster rebels and occupied a fort near Smerwick. Grey marched against them, forced them to surrender unconditionally, held the officers to ransom, and put the men to the sword. Then he ravaged Munster, leaving famine to complete the work. On campaigns Spenser saw "such wretchednesse as that any stonye harte would have rued the same." With Grev's recall in 1582 Spenser lost his secretaryship; but in the previous year he had acquired a clerkship for the faculties (i.e., licences and dispensations) in the Dublin chancery; and he had begun to obtain leases of forfeited houses and lands at modest rents which he did not always pay. At one of these houses, New Abbey in Co. Kildare, he seems to have resided occasionally in 1583 and 1584. But his headquarters were still in Dublin. We get a pleasant glimpse of him there in Ludovick Bryskett's Discourse of Civil Life. Bryskett tells us how a distinguished company, including the primate of Armagh, and soldiers like Norreys and St. Leger, met at his cottage near Dublin. Spenser suggested that their host should read them his translation of Giraldi da Cinthio's Discourse of Civill Life; which Bryskett accordingly did. The reading lasted for three days, being interspersed with discussions. On the third day Spenser interposed again, urging (to our astonishment) Aristotelian objections to the immortality of the soul. But Bryskett is simply putting into his mouth the arguments given by Giraldi to Torquato. It is doubtful, indeed, if this famous discussion ever took place at all, for Bryskett imitates Giraldi not only in the substance of his dialogue but in its setting. But if it never actually occurred it must be such as might have occurred.

In 1585 the centre of Spenser's interests began to shift to Munster. In that year he is found acting as deputy to Ludovick Bryskett in the clerkship of the council of Munster. In 1586 he held the prebend of Effin in Co. Limerick; and in that same year; under the Government's scheme for the plantation of Munster, he obtained a perpetual lease of Kilcolman Castle in Co. Cork with 3,028 acres of land. His resignation of his clerkship for the faculties in 1588 probably means that he then began to live at Kilcolman, where tradition says that his sister Sarah kept house for him. Here in 1589 he received a momentous visit from Raleigh. He had been engaged on the Faerie Queene intermittently for nearly ten years, receiving a fresh stimulus from Tasso's Gerusalemme Liberata, which reached him probably about the time of Lord Grey's recall. By 1589 three books were completed. Raleigh at once perceived their superlative merits and carried Spenser off to England to lay his poem at the queen's feet. It was licensed on Dec. 1, 1589 and published in 1590 with a dedication to the queen. Its reception can only be described as reverential. The great English epic so long awaited had appeared.

Spenser remained in England for more than a year, enjoying his fame, making friends with brother-poets, entertained at country houses, and acknowledged by his kinswomen of Althorpe,

Lady Carey, Lady Strange, and Lady Compton and Mountegle. But Burghley had not forgiven him; the substantial preferment for which he hoped was whittled down to a pension of £50 a year, and in 1591 he returned to Ireland a disappointed man Before leaving, he arranged for the publication of some of his minor poems, which appeared in 1591 as Complaints.

Complaints .- Of the Complaints, the Visions of Petrarch and Visions of Bellay are refurbishings of his schoolboy translations. The Ruines of Rome, a rendering of du Bellay's Antiquitez de Rome is clearly a juvenile production also. In the same kind, but much superior, is the original Visions of the Worlds Vanitie, in which, from Harvey's remarks, we may fairly recognize a fragment of the Dreams of 1580. The Teares of the Muses, mentioned in A Midsummer Night's Dream, V. i. 52, where Theseus dismisses it as "some satire, keen and critical," is an unconvincing complaint of the neglect of poetry, more excusable in 1580 than in 1590. The Ruines of Time laments various members of the Dudley family, including Sidney and Leicester, who had died in the previous decade: its present form belongs to 1590; but it probably incorporates some material collected for the Latin Stemmata Dudleiana; and the "Pageants" at the end may be another fragment of the Dreams. Mother Hubberds Tale was strengthened by the addition of a brilliant and bitter denunciation of the wretchedness of the suitor's state; and Spenser bated no jot of his satire on Burghley. Virgils Gnat, a free rendering of the Culex, has already been described. The one entirely new poem in the volume is Muiopotmos, which clearly belongs to 1590. Its theme recalls Sonnet 71, and may have been suggested simply by the sight of Lady Carey at her drawn-work. In spite of the grim ending the tone is so light-hearted that it seems perverse to read an inner meaning into this "airy trifle," with Burghley as the spider. Yet no reader would have suspected an inner meaning in Virgils Gnat but for the dedication to Leicester.

On reaching home, or so he would have us believe, Spenser wrote Colin Clouts Come Home Againe, dedicating it to Raleigh "from my house of Kilcolman the 27, of December 1501." It was not published, however, till 1595, when it appeared in one volume with Astrophel.

Colin Clout; Astrophel.—Colin Clouts Come Home Againe is the most charming of Spenser's poems. He is again in Arcady, telling his fellow-shepherds of his voyage with the Shepherd of the Ocean, his reception by the mighty Cynthia, her court, her ladies and brave poets. Then the note changes to the old complaint of courtly falsity and praise of the shepherd's life. The whole poem is exquisitely written, in "an easy running verse with tender feet." There is nothing more attractive in Spenser than Colin's chivalrous defence of Rosalind.

Astrophel is the prelude to a set of pastoral elegies on Sidney by several hands. The second "number," the Lay of Clorinda, though credited to Sidney's sister, is demonstrably from Spenser's pen. If Astrophel seems conventional and frigid we must remember that Spenser had already lamented Sidney in the Ruines of Time, and that the Sidney whom he now laments is not the hero of Zutphen but the author of the Arcadia.

Colin's praise of the shepherd's life prepares us to find that Spenser, though disappointed of preferment in England, and harassed by law-suits with his Irish neighbour Lord Roche, had begun to love his Munster home and to weave its legends and scenery into his verse. Towards the close of 1592, on the orthodox view of the Amoretti, he fell in love with Elizabeth Boyle and married her on June 11, 1594. He celebrated his wooing in the Amoretti and his wedding in the Epithalamion, which were entered together at Stationers' Hall in November 1594, and published together in 1595. It is highly probable that some of the Amoretti had already done service to express an amour courtois for Lady Carey during his English visit. It is probable that Elizabeth Boyle was the orphan daughter of Stephen Boyle, of Bradden in Northamptonshire, who had accompanied her brother

'Yet the dedication of Daphnaida is dated "London this first of Januairie, 1591" (i.e., 1592 n.s.). No convincing explanation of this discrepancy has been offered. On the whole it is easiest to believe that Spenser, writing on New Year's Day, used the new style, i.e., that his 1501 means our 1501.

Alexander when he went to Ireland to seek his fortune under the protection of their kinsman Richard Boyle, afterwards earl of Cork. The view that she was a widow, having been married to one Tristram Peace in 1588 or 1589, at present lacks documentary confirmation, and is hard to reconcile with Burke's statement that she bore seven children to her third—on this view her fourth—husband, Sir Robert Tynte, after 1612 or 1613.

Amoretti; Epithalamion .- The Amoretti are love-sonnets, all but one in a form which Spenser made his own, consisting of three linked quatrains and a couplet. It had already been used in Scots, but Spenser may have got it direct from Marot. Though it lacks the pyramidal strength of the Petrarchan form, and the freedom of the Shakespearean, its "linked sweetness" suits Spenser's style. Many of these sonnets are imitated from French or Italian, especially from Desportes and Tasso: for one a Spanish original has been found. They are all graceful, but only the famous sonnet on Easter can be called great. The Epithalamion, on the other hand, is by common consent the greatest of all weddingsongs; rich in poetic allusions and in echoes from his own earlier poems, as if Spenser had gathered up all the fruits of his study and all the flowers of his fancy to present them to his bride. Here for once his whole nature speaks, flesh and spirit reconciled in the sacrament of marriage. The stanza, suggested by the Italian canzone, is magnificent far beyond anything previously heard in English. The structure of the whole poem is as perfect as that of its parts.

Towards the end of 1595 Spenser, having finished three more books of the Foerie Queene, came to London to publish them. During this year he also published his Prothalomion and Fourne Hymnes, and composed or revised his Veue of the Present State of Ireland, which, though entered at Stationers' Hall in 1598, was not allowed to be printed without further authority, and, in fact, did not see the light till 1633.

Prothalamion; Hymnes; Veue of the Present State of Ireland.—The Prothalamion graced the wedding of two of the Earl of Worcester's daughters, who were married together from Essex house. Though it lacks the glow and sweep of the Epithalamion, it is, if possible, even more perfect in metre and diction.

The hymns of Heanvenlie Love and Heavenly Beauty were written in 1596 to propitiate two pious noblewomen and counteract the hymns in Honour of Love and in Honour of Beautie written in his youth. So Spenser avers; but to print the earlier hymns was scarcely the way to ensure their oblivion.

In the Veue of the Present State of Ireland Irenaeus expounds to Eudoxus the causes of the Irish troubles and propounds a cure. Irish laws, customs and religion must all be reformed on the English model. But subjugation must precede reform. Vacillation has been the curse of the Government. Let them now bring over 10,000 foot and 1,000 horse, plant these in six convenient garrisons, give the rebels 20 days in which to surrender, and then hunt down relentlessly all who stand out. Two winter campaigns will break their spirit. Let a fresh offer of pardon then be made, and rebellion will be at an end. There follows a detailed scheme, supported by statistics, for the administration of the pacified areas, ending with a proposal for the appointment of a lieutenant-general, Essex being clearly indicated. Political antagonism and racial antipathy combined with religious hatred to blind Spenser to the Irish cause.

During this second visit to England Spenser's hopes of preferment were centred in the Earl of Essex, but again he sued in vain. He returned to Kilcolman, probably in 1597, and resumed the Faerie Queene. In Sept. 1598 he was recommended for the sherifidom of Cork. But preferment came too late: in October Tyrone's rebellion had broken out, the Munster Irish rose, Kilcolman Castle was burned and Spenser fled with his family to Cork. From Cork he was sent to London with a dispatch which bears date Dec. 9, 1598. Along with it he brought a brief note of his own in which he reiterated the policy of the View. On Jan. 16, 1599 he died. He was buried in Westminster Abbey close to Chaucer; many nobles attended his funeral, and his fellow-poets brought elegies which they threw into his grave with the pens that had written them. Spenser's tragic reversal of fortune

and sudden death gave rise to a crop of legends. Ben Jonson told Drummond that one of Spenser's children perished in the flames of Kilcolman Castle and that he himself died "for lack of bread." It is only too likely, after all he had gone through, that Spenser collapsed on reaching London, and was a dying man before his friends could learn of his condition and come to his aid. Two more cantos of the Faerie Queene with two stanzas of a third were published in 1609; if more was written, as is probable, after 1596, it is irrecoverably lost.

The Faerie Queene.-Spenser's place among the great poets depends on the Faeric Queene, a fragment of a great poem which was to have been "disposed," as the title informs us, "into XII. bookes fashioning XII. morall vertues," each virtue embodied in a knight, and the whole designed "to fashion a gentleman or noble person in vertuous and gentle discipline"-at once a chivalric romance and a handbook of morals and manners; nay more-for Spenser would emulate Virgil as well as Ariosto-a national epic to the glory of England's Elizabeth. Such a threefold cord is not easily twined. Yet the task seemed feasible to Spenser, because to him the eternal war of good and evil, which was his essential theme, was embodied in the struggle of Protestant England against her Catholic foes. Book I indeed may be read not inconsistently either as a mere romance, or as the spiritual experience of an elect Christian, or as a history of the English Church in the sixteenth century. But in Book II. the story stands still for nearly two whole cantos; the tale of Hellenore in Book III. is told with a gusto ill calculated to fashion a gentleman in virtuous discipline; in Book IV. the poet grows so careless of his characters that he lets the long-parted lovers come together without recognizing one another; the recent history of Book V. has little allegorical or romantic interest; and Book VI. ends in a burst of sheer pastoralism in which the poet forgets his allegory as completely as the hero forgets his quest. Only Spenser's contemporaries could fully appreciate the historical element, and some of it even to them can only have had the interest of a roman à clef; yet it strengthens the texture of the poem, and gives figures like Arthegall and Satyrane some firmness of outline.

The allegory was treated with respect for two centuries; Milton thought "our sage and serious poet" a better teacher than Scotus or Aquinas; modern criticism has too often followed Hazlitt in commending the poem to readers with the assurance that the allegory won't bite them. But to ignore the allegory is to ignore the informing purpose of the whole, without which the story would be a mere series of ill-joined episodes, and much of the imagery meaningless, some of it grotesque or even repulsive. The ethical, as distinct from the structural, value of the allegory must depend on the worth of the ideas it embodies, as its poetical value depends on the imaginative force of their embodiment. Spenser was not an original nor a systematic thinker. His philosophy is a blend of Platonism refracted through Ficino, Aristotelianism of the scholastic tradition, and Christianity with a Calvinistic bias. And the elements do not perfectly combine. Thus the doctrine of love and beauty, by which Ficino thought to reconcile the love of woman with the love of God, this doctrine, brilliantly expounded in the first two Hymns, is fundamentally irreconcilable with the scheme of salvation through the atoning sacrifice of Christ which is expounded in the third Hymn. The poet was a sincere and militant Christian, but also a man sensitive to the allurements of the world and the flesh; he knew self-distrust. and weariness, and regret for evanescent youth, and is never so moving as when he writes out of such experiences or turns from this unstable life in longing for the eternal rest.

Of the romance itself, with its wealth of imagery and melody, there has never been but one opinion. Like all Spenser's work it is highly imitative. He rifled romantic literature for incidents and situations. The descriptions in which he excels constantly recall works of art—picture, tapestry, pageant or masque. But he owed much also to real life; he was recommended for his sherifidom as "not unskilful or without experience in the wars"; and his journeys through the wild woods of Munster and his intercourse with soldiers like Grey and Norreys yielded many a hint for the background and characters of the F.O. Its diction.

archaic but not rustic, and rich in strange coinages and terms of chivalry, is in keeping with its remote and old-world air. Not less appropriate is the stanza which he invented, not by "extending" the ottava rima or the rhyme royal, but by adding to the linked quatrains which he had used in the SC. an Alexandrine such as Ferrars had employed to tip his sestets. The elements are not new; the miracle lies in their combination. It is not a perfect stanza for narrative, nor indeed is Spenser a perfect storyteller; but its amplitude fits the slow tempo of his thought, as he unrolls his leisurely pageants or ponders on time and change. Its power must not be judged by single stanzas, but by the cumulative effect as stanza after stanza rolls in, each ninth wave breaking higher than the rest.

Spenser has not Chaucer's genial breadth, nor Milton's art, nor Wordsworth's vision; but in the purely poetic gifts he is inferior to Shakespeare alone. The "school of Spenser" was small and short-lived, quite eclipsed in the next generation by Jonson and Donne; but in a wider sense all later English poets

have been his scholars.

Beeston described Spenser to Aubrey as a little man, with short hair, little band and little cuffs-a description that fits the Pembroke College portrait better than the beruffled exquisite of the Dupplin portrait. These two portraits, whether genuine or not, do aptly illustrate the two sides of Spenser, scholar and Puritan on the one hand, courtier and man of affairs on the other; fundamentally a poet, sensitive and fastidious, yet responsive to the claim of affection or of honour. "Entire affection hateth nicer hands"; "No service loathesome to a gentle kind"; "The noblest mind the best contentment has"-in such lines we hear his authentic voice.

BIBLIOGRAPHY .- Dates of first issues are given above. Folios in 1609 BIBLIOGRAPHY.—Dates of first issues are given above. Folios in 1609 (F.Q. only), 1611—13, 1671, 1670 (said to have been "overseen" by Dryden). Editions by J. Hughes (1715), H. J. Todd (1805), F. J. Child (1855), J. P. Collier (1862), R. Morris and J. W. Hales (1860), A. B Grosart (1883—84), R. E. N. Dodge (1908), J. C. Smith and E. de Sélincourt (1909—10). F.Q. only by R. Church (1758), J. Upton (1758), K. M. Warren (1897—1900). S.C. by C. H. Herford (1805). Fourer Hymnes by L. Winstanley (1907). Commentaries and criticisms by J. Jortin (1714), T. Warton (1752), G. L. Craik (1845), R. W. Church (1879), J. J. Higginson (S.C. only) (1912), E. Legouis (1923), W. L. Renwick (1925). Much of the recent work on Spenser has been done by American scholars: F. I. Carpenter, E. A. Greenlaw, J. Erskine, J. B. Fletcher, P. W. Long, C. G. Osgood, F. M. Padelford, C. H. Whitman, etc. Most of it is available only in periodicals, Car-C. H. Whitman, etc. Most of it is available only in periodicals. Carpenter's Reference Guide (1923), Osgood's Concordance (1915), and Whitman's Subject Index (1918) are indispensable for detailed study. (T. C. SM.)

SPENSERIAN STANZA, a verse-form so called from its invention by Edmund Spenser for his Faerie Queene (1590). Its origin is disputed; Schipper derives it from the Old French ballade (q.v.), others from the Italian ottava rima. Probably, however, it is Chaucer's eight-line Monk's Tale stanza, with a ninth line (an alexandrine) added, a feature which gives the stanza its beauty. The rhyme-scheme is a b a b b c b c c + (the + denoting the extra foot in the last line). Spenser's sonnet-scheme is somewhat similar. The stanza was hardly used in the 17th century, though Giles and Phineas Fletcher made for themselves adaptations of it. About 1740 it was revived, by Akenside (Virtuoso, 1737), Shenstone (Schoolmistress, 1742) Thomson (Castle of Indolence, 1748); followed by Beattie (Minstrel, 1771) and Mrs. Tighe (Psyche, 1805). Since 1850 it has been rarely employed. It is a purely English form.

SPERANSKI, COUNT MIKHAIL MIKHAILOVICH (1772-1839), Russian statesman, the son of a village priest, spent his early days at the ecclesiastical seminary in St. Petersburg (Leningrad), where he rose to be professor of mathematics and physics. His brilliant intellectual qualities attracted the attention of the government, and he became secretary to Prince Kurakin. In 1806, the emperor Alexander I. took him to the conference of Erfurt and put him into direct communication with Napoleon, who described him as "the only clear head in Russia." They discussed Russian reforms.

From 1809 to 1812 Speranski was all-powerful; he replaced the earlier favourites, becoming practically sole minister. In 1810 and the first half of 1811 Speranski was still in high favour,

and was the confidant of the emperor in that secret diplomacy which preceded the breach of Russia with Napoleon.

On the eve of the struggle with Napoleon, Alexander, conscious of his unpopularity, conceived the idea of making Speranski his scape-goat, and so mobilising Old Russian sentiment against revolutionary France. The grand-duchess Catherine, Karamzin, Rostopchin and the Swedish general Baron Armfield, intrigued to involve him in a charge of treason. Alexander did not credit the charge, but on March 29, 1812 he dismissed him from office. Reinstated in the public service in 1816, he was appointed governorgeneral of Siberia, for which he drew up a new scheme of government, and in 1821 entered the council of state. He died on Feb. 11, 1839, at St. Petersburg.

See the biography (in Russian) by M. Korff (St. Petersburg, 1861) and the works of V. Vagin (St. Petersburg, 1872, Moscow, 1905). SPERMACETI, a wax found in the head cavities and blubber of the sperm whale (Physeter macrocephalus), where it is dissolved in the sperm oil while the creature is living (from Lat. sperma, seed, and cetus, a whale). It also occurs in other Cetacea (see WHALE OIL). It is mainly cetin or cetyl palmitate, C15H31CO2C16H33. The substance is used in making candles, in the dressing of fabrics, in medicine and surgery, and in cosmetic preparations. (See Oils, Fats and Waxes.)

SPERMOPHILE, a name applied to a group of squirrel-like rodents (Citellus), widely distributed in the northern hemisphere. Most spermophiles hibernate and all have internal cheek pouches. In Russia they are known as sousliks and in the United States as ground squirrels or gophers. (See Ground Squirrel; Sous-LIK.)

SPERMOPHYTA or SPERMATOPHYTA, the name often used in botany to denote the seed-plants, including the true flowering plants, or angiosperms (q.v.), and the conifers and their allies or gymnosperms (q.v.)

SPERM WHALE (Physeter catodon), the largest of the toothed whales, called also cachalot, its size being about equal to those of the Arctic right whale. The head is about one-third of the length of the body, massive, high and truncated in front. It owes its size and form to the accumulation of a peculiar form of fatty tissue in the large hollow on the upper surface of the skull. The oil contained in cells in this cavity, when refined, yields spermaceti, and the sperm oil of commerce comes principally from the thick covering of blubber, which envelops the body. Ambergris, used in perfumery, is a concretion formed in the intestine, and found floating on the sea. (See CETACEA; SPERMACETI.)

SPERRY, ELMER AMBROSE (1860-1930), American inventor, was born at Cortland, N.Y., on Oct. 12, 1860. He began early to experiment with electric arc lights and in 1879 established a factory in Chicago to manufacture an improved model which was highly successful. He then turned his attention to the development of electric mining machinery, invented the electric rotary and the chain undercutting machines, devised and built his own electric mining generator and other mining apparatus and established another factory to manufacture this machinery. He next designed an electric locomotive for industrial work, and developed motor and transmission machinery for street cars, which resulted in the founding of the Sperry Electric Railway Co. of Cleveland. About 1900 he established a research laboratory in electro-chemistry at Washington, D.C., where he invented the chlorine detinning process and also the electrolytic process for producing white lead from impure by-product lead. In 1915 he announced his high-intensity arc searchlight, built upon an entirely new principle, allowing a brilliancy as high as 900 candle-power per square millemetre, whereas 160 was the highest obtainable previously. The electrical and mechanical means of operating, as well as the mechanism to control the high temperatures of the arc, represented a difficult engineering achievement. These searchlights have become the standard for the principal armies and navies of the world and are in use for aircraft and coast beacons, the largest giving a white light of 1,500,000,000 candle-power which can be seen for upwards of 150 miles.

Sperry's most important inventions were based upon the application of the gyroscope in which he was always greatly interested.

Chief of these is the gyrocompass (q v.), first installed on the battleship Delaware in 1911. This compass, unaffected as it is by iron and steel, entirely superseded the magnetic compass on submarines and battleships and was placed likewise on merchant ships. Upon it the whole complicated system of modern naval gunnery was developed. (See Gunnery, Naval.) Sperry also designed and manufactured electrically sustained gyros for torpedoes which enabled them to complete long trajectories with a high degree of accuracy. During World War I he also developed aerial torpedoes with automatic gyrocontrol which proved effective at a range of 35 mi. Quantity manufacture had begun when the war ended. Further experiments yielded the gyropilot for the steering of ships, the automatic gyropilot for stabilizing aeroplanes, the gyroscopic roll and pitch recorder for the testing of ships, and, finally, a gyroscopic ship stabilizer which was installed on a number of ships in the United States, British, Italian and Japanese navies. The motion of a ship in the waves is almost completely neutralized by antomatic counter movements of the gyroscopes.

Sperry served after 1915 as a member of the naval consulting board, and published numerous scientific papers. He died at Brooklyn on June 16, 1930.

See "The Engineering and Scientific Achievements of Elmer A. Sperry," in Mechanical Engineering, vol xlix (1927).

SPES, properly bona spes ("good expectation," i.e., hope), a goddess worshipped in Rome from an uncertain but doubtless early date (temple in the Forum Holitorium, or vegetable market, vowed during the first Punic War, cf. Tibullus i, 1, 9, cf. ii, 6, 21). Possibly she was originally an agricultural deity, not the personification of hope in general.

See Wissowa, Religion und Kultus, 2nd ed , p. 329.

SPESSART, a highland forest district belonging mainly to the Bavarian province of Lower Franconia, but in the north to the Prussian province of Hesse Cassel.

SPEUSIPPUS (4th century B.C.), Greek philosopher, son of Eurymedon and Potone, sister of Plato, is supposed to have been born c. 407 B.C. He was bred in the school of Isocrates, but when Plato returned to Athens c. 387, Speusippus became a member of the academy. In 361, when Plato undertook his third and last journey to Sicily, Speusippus accompanied him. In 347 the dying philosopher nominated his nephew to succeed him as scholarch, and the choice was ratified by the school. Speusippus held the office until his death in 339.

Of his many philosophical writings nothing survives except a fragment of a treatise On Pythagorean Numbers. It is gathered in regard to his theory of being that whereas Plato postulated as the basis of his system a cause which should be at once Unity, Good and Mind, Speusippus distinguished Unity, the origin of things, from Good, their end, and both Unity and Good from controlling Mind or Reason; whereas Plato recognized three kinds of numbers-firstly, ideal numbers, i.e., the "determinants" or ideas; secondly, mathematical numbers, the abstractions of mathematics; and thirdly, sensible numbers, numbers embodied in things-Speusippus rejected the ideal numbers, and consequently the ideas; Speusippus traced number, magnitude and soul each to a distinct principle of its own. In his theory of knowledge he held that a thing cannot be known apart from the knowledge of other things; for, that we may know what a thing is, we must know how it differs from other things, which other things must therefore be known; accordingly, in the ten books of a work called "Ομοια, he attempted a classification of plants and animals; the results thus obtained he distinguished at once from "knowledge" and from "sensation" holding that "scientific observation" though it cannot attain to truth, may, nevertheless, in virtue of a certain acquired tact, frame "definitions." In his theory of ethics he denied that pleasure was a good, but seemingly was not prepared to account it an evil.

Hence, though, like Plato, Speusippus studied the differences of natural products with a view to classification, he did not agree with Plato in his conception of the significance of the results thus obtained; i.e., while to Plato the definition derived from the study of the particulars included in a natural kind was an approximate definition of the idea in which the natural kind originated, to Speusippus the definition was a definition of the particulars studied

and, strictly speaking, of nothing else. Thus while Plato hoped to ascend through classificatory science to the knowledge of eternal and immutable laws of thought and being, Speusippus, abandoning ontological speculation, was content to regard classificatory science not as a means but as an end and to rest in the results of scientific observation.

In abandoning the theory of ideas-that is to say, the theory of figures and numbers, the possessions of universal mind, eternally existent out of space and time, which figures and numbers when they pass into space and time as the heritage of finite minds are regarded as things-Speusippus had the approval of both the Platonists generally and Aristotle. But, whereas the new scholarch, confining himself to the detailed examination of natural kinds, attempted no comprehensive explanation of the universe, Aristotle held that a theory of its origin, its motions, and its order was a necessary adjunct to the classificatory sciences. In nearly all of his references to Speusippus, Aristotle insists upon this fundamental difference in procedure. Conceiving that the motions of the universe and its parts are due to the desire which it and they feel toward the supreme external mind and its several thoughts, so that the cosmical order planned by the divine mind is realized in the phenomenal universe, Aristotle thus secures the requisite unification, not, indeed, of mind and matter, for mind and matter are distinct, but of the governing mind, the prime unmoved movent, since it and its thoughts are one. On the other hand, when Speusippus distinguishes One, Good and Mind so that Mind, not as yet endowed with an orderly scheme, adapts the initial One to particular goods or ends, his theory of nature appears to his rival "episodical"; i.e., to consist of a series of tableaus wanting in dramatic

Speusippus and his contemporaries in the school exercised an important and far-reaching influence upon Academic doctrine. It would seem that Academic scepticism began with those who had been reared by Plato himself, having its origin in their acceptance of the scientific element of his teaching apart from the ontology which had been its basis.

(1852); Zeller, Die Philosophie d Griechen, II, i (Leipzig, 1875); Mullach, Frag. Phil. Graecorum, iii (1881); and Überweg, Grundriss der Gesch. der Philosophie, Bd. I (1926).

SPEY, river in the highlands of Scotland, rising from Loch Spey (1,143 ft.) in the Corrievairack forest, Invernesshire about ro mi. S.S.E. of Fort Augustus. It runs about roo mi. N.E. and enters the Moray firth at Kingston. It is one of the longest and most rapid rivers of Scotland, famous for its salmon fishing and is fed by waters from the Monadhliath hills, the Grampians and the Caimgorms. There is a great deal of glacial drift in the Spey valley. It is now largely denuded of its conifers by felling. The lower section of the valley is known as Strathspey.

SPEYER or Spires, a town and episcopal see of Germany, in the Rhineland palatinate, situated on the left bank of the Rhine. at the mouth of the Speyerbach, 16 mi. S. of Mannheim by rail. Pop. (1950) 31,841. Speyer, known to the Romans as Augusta Nemetum or Nemetae, and to the Gauls as Noviomagus, appears under the form of Spira about the 7th century. Captured by Julius Caesar in 47 B.C., it was repeatedly destroyed by the barbarian hordes in the first few centuries of the Christian era. The town had become an episcopal seat in the 4th century; but heathenism supervened, and the present bishopric dates from 610. In 830 Speyer became part of the Frankish empire. The contentions between the bishops and the citizens were as severe as in any other city of Germany. The situation of the town opposite the mouths of several roads through the Rhine valley early fostered its trade; in 1294 it rose to be a free imperial city. It enjoyed great renown as the seat of the imperial supreme court from 1527 until 1689. Numerous imperial diets assembled there. From 1801 until 1814 it was the capital of a department of France; but it was restored to Bavaria in 1814.

A basilica of sandstone, the cathedral has a peculiar importance in the history of architecture as probably the earliest Romanesque basilica in which the nave as well as the side arcades was vaulted from the first. Built in 1030–1061 by Conrad II and his successor, this church has had a chequered history, its disasters culminating in 1689, when the soldiers of Louis XIV burned it to the bare walls and scattered the ashes of eight German emperors. Restored in 1772–1784 and provided with a vestibule and façade, it was again descerated by the French in 1794; but in 1846–1853 it was once more thoroughly restored and adorned in the interior with gorgeous frescoes. Speyer, although rebuilt in 1697, has never recovered from the injuries inflicted by the French in 1689. Its manufactures include paper, tobacco and cigars, sugar, machines, lead, vinegar, beer and musical instruments.

SPEZIA, or La Spezia, a city of Liguria, Italy, 49 ft. above sea level. Pop. (1951), 109,978 (commune). It is the chief naval harbour of Italy; was adopted as such in 1861 though Napoleon I had entertained the idea. The Bay of Spezia (anc. Portus Lunae) is sheltered from all except southerly winds, and on its western shore are numerous openings, which afford perfectly safe anchorage in all weathers. The entrance is protected by forts, while a submarine embankment, 2 mi. long, renders it secure. Its important arsenal dates from 1870. The establishment of San Vito is devoted entirely to the production of artillery; that of San Bartolomeo is exclusively used for electrical works and the manufacture of submarine weapons, especially torpedoes. The museum contains a unique collection of menhirs from the neighbourhood cut into the form of human figures. Spezia probably arose after the destruction of Luna. It was sold by the Fieschi in 1276 to Genoa. The town was fortified by its new possessors and made the seat of a governor of some importance. It became a city in the 16th century.

Spezia and its naval installations were heavily bombed by the Allies in World War II.

SPHALERITE, a sulphide of zinc, ZnS, crystallizes in the tetrahedral class of the isometric system. The name derives from  $\sigma\phi\alpha\lambda\epsilon\rho\delta\rho$ , "treacherous," in allusion to the ease with which the dark coloured, opaque varieties are mistaken for the lead sulphide galena. The synonyms blende and zincblende, from the German blind, "blind," similarly allude to the fact that it does not yield lead. The crystal structure of sphalerite is based on a tetrahedral, four-co-ordinated framework of zinc and sulphur atoms in which the bonding is essentially covalent. The structure is similar to that of diamond, and may be imagined as derived therefrom by the alternate substitution of zinc and sulphur atoms for carbon. The unit cell dimension is 5.40 A.

The common crystal forms are the tetrahedron and the dodecahedron. The crystals frequently occur as simple or multiple contact twins, or as complicated lamellar intergrowths, in which the twin axis is [111]. Sphalerite ordinarily occurs in massive granular form, less commonly as fibrous aggregates with a layered structure or as dense microcrystalline masses. It has a welldeveloped dodecahedral cleavage, and the fracture is conchoidal. The hardness is  $3\frac{1}{2}$  to 4, and the specific gravity of pure material is 4.0. The colour varies widely. Generally it is a shade of brown, but some sphalerite is green, yellow or, in crystals of high purity, almost colourless. Material containing iron is brownish black or black. Sphalerite may fluoresce when irradiated with ultraviolet light or X-rays, and some specimens emit light when scratched with a sharp point (triboluminescence). According to the formula, ZnS, sphalerite contains 67.1% Zn and 32.9% S. Usually, however, it contains iron in solid solution up to a limit of about 26%, and both manganese and cadmium may be present in small amounts.

Sphalerite, the most common zinc mineral, and galena, the most abundant ore of lead, are intimately associated in most of the important deposits of these metals. Other associates include chalcopyrite and pyrite among metallic minerals, and quartz, barite, dolomite, calcite and siderite as gangue minerals. In the United States the most important deposits of sphalerite are found in the Mississippi Valley region. There it occurs chiefly with chalcopyrite, galena, marcasite and dolomite in solution cavities and brecciated zones in limestone and chert. Similar deposits occur elsewhere—in the region of Silesia in Poland, the Moresnet

district in Belgium, and North Africa. Sphalerite also has world-wide distribution as an ore mineral in hydrothermal vein deposits, in contact metamorphic zones and in high temperature replacement deposits. Crystals of outstanding beauty and perfection are found in cavities in a dolomite rock in the Binnenthal, Switz., and a transparent variety of a golden colour occurs at Picos de Europa, Santander, Sp. Fine specimens also come from Cornwall, Derbyshire and Cumberland in England, and from Bottino in Tuscany, It.

SPHENE or Titanite, a mineral consisting of calcium titanosilicate, CatīsiOs, crystallizing in the monoclinic system. The crystals vary considerably in habit, but are generally thin and wedge-shaped; hence the name sphene (Gr.  $\sigma\phi\dot{\eta}\nu$ , a wedge). The colour is green, yellow, brown or black, and the lustre resinous to adamantine; crystals are transparent to opaque. The hardness is 5.5, specific gravity 3.5. Sphene is cut as a gem stone, though it is rather too soft to stand much wear; owing to its high dispersive power it gives brilliant flashes of prismatic colours. As small crystals, it is found in igneous rocks (granite, syenite, trachyte, phonolite, etc.), and also in gneiss, schist, crystalline limestone and pegmatite.

SPHENISCIDAE: see Penguin. SPHENODON: see Reptiles.

SPHERE, in Greek geometry, the solid generated by the revolution of a semicircle about its diameter as an axis. In modern elementary geometry it is more generally considered as the spherical surface so generated, or as the locus of points at a constant distance from a fixed point called the centre. The constant distance is called a radius, and any line segment through the centre and limited at both ends by the sphere is called a diameter. In the geometry of surfaces it is defined as the quadric surface passing through the circle at infinity. Any section made by a plane cutting a sphere is a circle, being a great circle if the plane passes through the centre, and otherwise a small circle. The solid cut off by the plane of a great circle, is a hemisphere; that cut off by the plane of a small circle, a segment. In analytical geometry, the equation of a sphere in rectangular Cartesian co-ordinates is  $x^2+y^2+z^2=a^2$ , and in polar co-ordinates it is r=a. If the centre is  $(a, \beta, \gamma)$ , the Cartesian equation becomes

$$(x-a)^2+(y-\beta)^2+(z-\gamma)^2=a^2$$
.

The surface of a sphere is found by the formula  $S=4\pi r^2$ , the area being four times that of a great circle. The volume is  $\frac{4}{3}\pi r^3$ . Analogous to the propositions of plane geometry and trigonometry is a series of propositions relating to the sphere. (See Analytical Geometry; Astronomy; Geodesy; Projective Geometry; Solids, Geometric; Surface; Trigonometry.)

SPHERES OF INFLUENCE. "Spheres of influence" is a diplomatic term which signifies the claim on the part of a state to exclusive control within a foreign territory. This control can be economic, military or political, or it may concern the overall government of the territory. The territory which is made the object of a sphere of influence may be either politically unorganized, as were some of the African territories which were transformed into spheres of influence toward the end of the 19th century, or it may be under the sovereignty of a weak government, as were, for instance, Morocco, Ethiopia and Persia when they were divided into spheres of influence at the beginning of the 20th century. The term may refer to a political claim to exclusive control, which other nations may or may not recognize as a matter of fact, or it may refer to a legal agreement by which another state or states pledge themselves to refrain from interference within the sphere of influence.

It is in the latter, legal significance that the term first gained currency in the 1880s. Its coming into usage was closely connected with the consummation of the colonial expansion of the European powers in Africa and Asia. The last stage of that expansion was characterized by the endeavour of all major colonial powers to carry on the mutual competition for colonies peacefully through agreed-upon procedures and the appeal to common standards of action rather than adoption of violent means. Agreements on spheres of influence served this purpose. Thus, the agreement

between Great Britain and Germany in May 1885, the first to make use of the term, provided for "a separation and definition of their respective spheres of influence in the territories of the Gulf of Guinea." In it "Great Britain engages not to make acquisitions of territory, accept Protectorates, or interfere with the extension of Guinea which lies east of" a defined line. "Germany engages not to make acquisitions, accept Protectorates, or interfere with the extension of British influence in that part of the coast and interior of Guinea which lies between the line as above described . . . and the British Colony of Lagos. Both Powers agree to withdraw all Protectorates which they have already established within the limits hereafter assigned to the other party . . . Germany declares herself ready . . . to refrain from making acquisitions of territory or establishing Protectorates on the coast between the Colony of Natal and Delagoa Bay."

This agreement was followed by many of a similar nature, of which article vii of the agreement between Great Britain and Germany of July 7, 1890, concerning East Africa may be regarded as typical. Its text is as follows: "The two Powers engage that neither will interfere with any sphere of influence assigned to the other by Articles I to IV. One Power will not in the sphere of the other make acquisitions, conclude Treaties, accept sovereign rights or Protectorates, nor hinder the extension of influence of the other. It is understood that no Companies nor individuals subject to one Power can exercise sovereign rights in a sphere assigned to the other, except with the assent of the latter."

Agreements of this type concerned territories politically unorganized and therefore subject to occupation by whatever nation complied with the rules of international law relative to the acquisition of unoccupied territory. Agreements of another type, often called spheres of interest, refer to territories which are already politically organized and are to be transformed into a sphere of influence of one of the contracting parties. This type is exemplified by article ii of the Anglo-French agreement of April 8, 1904, concerning Morocco. It provides: "The Government of the French Republic declare that they have no intention of altering the political status of Morocco. His Britannic Majesty's Government, for their part, recognize that it appertains to France, more particularly as a Power whose dominions are conterminous for a great distance with those of Morocco, to preserve order in that country, and to provide assistance for the purpose of all administrative, economic, financial, and military reforms which it may require. They declare that they will not obstruct the action taken by France for this purpose. . . ."

Of the legal effects of such agreements, three are worthy of note. First, agreements establishing spheres of influence create rights and obligations between the contracting parties only. States which are not parties to the agreement are legally free to acquire within the sphere of influence whatever rights they can; they have, however, for political reasons generally refrained from interference and acted as though they, too, were bound by the agreement. Second, such agreements do not affect by themselves the actual control over the territories concerned. So long as the state in whose favour a sphere of influence has been established chooses not to exercise its exclusive rights within that sphere, the actual control over it remains in the hands of those who exercised it when the agreement was concluded. Third, once the state in whose favour a sphere of influence has been established makes use of its rights within that sphere, all states, whether or not they are parties to the agreement, are excluded from the territory to the extent that the former state exercises actual control.

When the period of colonial expansion came to a close with the outbreak of World War I, spheres of influence in the legal sense lost much of their importance. From then on, the term was used more and more for the unilateral political claims of great powers, as old as political history itself, to a predominant position in the territories of other nations, especially those adjacent to their own. Thus, it can be said that the Monroe Doctrine, especially in its application after the time of Theodore Roosevelt, established the western hemisphere as a sphere of influence for the United States. In the aftermath of World War II, the Soviet Union created a sphere of influence as a political fact in the territories of

the nations of eastern Europe and of the Balkans, with the exception of Greece (and later Yugoslavia). The political division of the Balkans into spheres of influence in the political sense was foreshadowed in the agreements concluded between Great Britain and the Soviet Union in 1944 and on the face of them intended only to facilitate military operations and not to outlast the war. These agreements were opposed by U.S. Secretary of State Cordell Hull, who was not "a believer in the idea of balance of power or spheres of influence as a means of keeping the peace" (from Cordell Hull, The Memoirs of Cordell Hull, vol. in, p. 1452, copyright 1948 by Cordell Hull, the Macmillan Company, 1948). Regardless of their evaluation, it seems that spheres of influence in the political sense are an inevitable concomitant of the struggle for power of sovereign nations. (See International Law; Monroe Doctrine)

Morgenthau (ed.), Peace, Security and the United Nations (1946); W. W. Willoughby, Foreign Rights and Interests in China, and ed, vol. 1, pp. 130–168 (1927).

**SPHERICAL HARMONICS** are certain functions which occur in the theories of gravitation, electricity, hydrodynamics, and many other branches of mathematical physics.

If a number of particles of masses  $M_1, M_2, \dots, M_m$ , attracting according to the inverse-square law, are placed at points  $A_1, A_2, \dots, A_m$ , the potential of these masses at any point P, i.e., the work done by the gravitational attractions in bringing a unit mass from an infinite distance to P, is

$$\frac{M_1}{A_1P} + \frac{M_2}{A_2P} + \cdots + \frac{M_m}{A_mP}.$$

If now the points  $A_1, A_2, \dots, A_m, P$  are referred to a set of rectangular co-ordinate axes, and the co-ordinates of the points are  $(a_1, b_1, c_1), (a_2, b_2, c_2), \dots, (a_m, b_m, c_m), (x, y, z)$  so that

$$A_1P = \sqrt{\{(x-a_1)^2 + (y-b_1)^2 + (z-c_1)^2\}}$$

with similar expressions for  $A_2P$ ,  $A_3P$ , ...,  $A_mP$ , and if V denotes the potential, it may be verified by partial differentiations that

$$\frac{\partial^2 V}{\partial x^2} + \frac{\partial^2 V}{\partial y^2} + \frac{\partial^2 V}{\partial z^2} = 0.$$

This equation does not involve the masses or the points at which they are placed, and so it is satisfied by the potential produced at a point (x, y, z), in free space, by any gravitating system; it is known as Laplace's equation, and it is frequently written in the form

$$\nabla^2 V = 0$$
,

 $\nabla^2$  denoting the differential operator  $\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2}$  for brevity.

Laplace's equation occurs in problems of Gravitation, Electrostatics and Hydrodynamics; the related equation  $\nabla^2 V = k \partial V / \delta t$  occurs in problems of conduction of heat, V being then a function of the co-ordinates x, y, z, and the time t, and k being a constant; and the equation  $e^2 \nabla^2 V = \partial^2 V / \partial t^2$  occurs in problems of Vibrations of air and ether, c being the velocity of sound or of light, according to the problem considered.

In order to discuss generally problems concerning the potential, it is found more effective to examine solutions of Laplace's equation than to regard the potential as the sum of a number of terms of the type M/AP, each term representing the potential produced by an attracting particle. If  $V_1$ ,  $V_2$ ,  $V_3$ , ·· are a number of solutions of Laplace's equation, and if

$$V = V_1 + V_2 + V_3 + \cdots$$

it is easily verified that

$$\nabla^2 V = \nabla^2 V_1 + \nabla^2 V_2 + \nabla^2 V_3 + \cdots = 0,$$

and so the sum of any number of solutions of Laplace's equation

is itself a solution of the equation. It is thus possible to build up a solution of Laplace's equation by adding together simpler solutions.

Now let V be any potential function, and suppose that it can be expanded by Taylor's theorem as a series of positive integral powers of x, y, z, thus

$$V = a_0+a_1x+b_1y+c_1z+a_2x^2+b_2y^2$$

$$+c_2z^2+d_2yz+c_2zx+f_2xy+a_3x^3+\cdots$$

Group together all terms which are of the same degree in x, y, z, and denote the groups of terms which are of degrees o, 1, 2,  $n, \cdots$  in the expansion by

$$Y_0(x, y, z)$$
,  $Y_1(x, y, z)$ ,  $Y_2(x, y, z)$ ,  $\cdots$ ,  $Y_n(x, y, z)$ ,  $\cdots$ , or, for brevity, by  $Y_0, Y_1, Y_2, \cdots, Y_n$ ,  $\cdots$ , so that

$$V = Y_0 + Y_1 + Y_2 + \cdots + Y_n + \cdots$$

The expression  $Y_n(v, y, z)$  is called a spherical harmonic of degree n. It may be verified that

$$\nabla^2 Y_2 + \nabla^2 Y_3 + \cdots + \nabla^2 Y_n + \cdots = \nabla^2 V = \mathbf{0}$$

so that the expression on the left vanishes identically; and since the terms written down are of different degrees, o,  $1, \dots, n-2 \dots$ , each must vanish separately, so that spherical harmonics are themselves solutions of Laplace's equation.

If the polar co-ordinates of (x, y, z) are  $(r, \theta, \phi)$ , so that

$$x = r \sin \theta \cos \phi$$
,  $y = r \sin \theta \sin \phi$ ,  $z = r \cos \theta$ ,

then  $Y_n(x, y, z)$  may be written in the form  $r^n f_n(\theta, \phi)$ , where  $f_n(\theta, \phi)$ 

is independent of r; and  $f_n(\theta, \phi)$  is called a surface harmonic. It can be proved that  $Y_n(x, y, z)/r^{2n+1}$  is also a solution of Laplace's equation, and it is called a spherical harmonic of degree -(n+1); this function and  $Y_n$  (x, y, z) are called solid harmonics.

The term spherical harmonics (German, Kugelfunktionen; French, Fonctions sphériques) is due to Lord Kelvin.

When referred to polar co-ordinates, Laplace's equation be-

$$\frac{\partial}{\partial r} \left( r^2 \frac{\partial V}{\partial r} \right) + \frac{1}{\sin \theta} \frac{\partial}{\partial \theta} \left( \sin \theta \frac{\partial V}{\partial \theta} \right) + \frac{1}{\sin^2 \theta} \frac{\partial^2 V}{\partial \phi^2} = 0;$$

this was the form of the equation originally given by P. S. de -Laplace in 1784, in a memoir on Saturn's rings.

Determination of Harmonics of Given Degree.-Let  $a_{r,s,t} x^r y^s z^t$  be an arbitrary expression of positive integral degree n in x, y, z where r, s, t are positive integers (zero included) such that r+s+t=n, and the summation extends over all possible sets of values of r, s, t. It is required to find conditions that this expression may be a harmonic.

It is readily proved that the number of terms in the expression is  $\frac{1}{2}(n+2)(n+1)$ ; if the expression is operated on by Laplace's operator, the result is an expression of degree n-2 in x, y, z, in which the  $\frac{1}{2}n(n-1)$  coefficients are linear combinations of the  $a_{r,s,t}$ . If the last expression is equated to zero,  $\frac{1}{2}n(n-1)$  equations connecting the are obtained, which have to be satisfied if the former expression is to be a harmonic. It follows that the number of independent coefficients areast is

$$\frac{1}{2}(n+2)(n+1)-\frac{1}{2}n(n-1)$$

i.e., 2n+1, and the remaining coefficients are expressible linearly in terms of them.

Consequently there are 2n+1 independent harmonics of degree n, and any other harmonic of degree n is expressible as a linear combination of these harmonics.

Take n=2 as an illustration; the expression

$$a_2x^2+b_2y^2+c_2z^2+2d_2yz+2e_2zx+2f_2xy$$

is a harmonic if  $a_2+b_2+c_2=0$ , and 5 independent harmonics of degree 2, in terms of which any harmonic of degree 2 may be expressed, may be taken to be

$$yz$$
,  $zx$ ,  $xy$ ,  $2z^2-x^2-y^2$ ,  $x^2-y^2$ .

The next step is to construct 2n+1 harmonics of degree n. This may be effected by considering the condition that

$$(ax+by+cz)^n$$

may be a harmonic, where  $a, b, \epsilon$ , are constants, and deducing the harmonics from it. By actual differentiation it follows that the condition that  $(ax+by+cz)^n$  is a harmonic is

$$a^2+b^2+c^2=0$$
;

and this condition is satisfied by taking

$$a = i \cos u$$
,  $b = i \sin u$ ,  $c = I$ ,

where u is any angle and i stands for  $\sqrt{(-1)}$ ; and so

$$(z+ix\cos u+iy\sin u)^n$$

is always a harmonic

Now suppose this expression to be expanded by the multinomial theorem, and replace cosu and sinu by their exponential values  $(e^{iu}+e^{-iu})/2$  and  $(e^{iu}-e^{-iu})/(2i)$ ; when the products of powers of  $\cos u$  and  $\sin u$  are multiplied out in this way, replace expressions such as emin, e-min by cos mu± sin mu.

It is thus possible to express  $(z+ix\cos u+iy\sin u)^n$  in the form

$$(z+ix\cos u+iy\sin u)^n = \frac{1}{2}g_0(x,y,z) + \sum_{m=1}^n [g_m(x,y,z)\cos mu + h_m(x,y,z)\sin mu],$$

where  $g_m(x,y,z)$  and  $h_m(x,y,z)$  are polynomials of degree n in x,y,z, and are independent of u; and since

$$\frac{1}{2}\nabla^2 g_0(x,y,z) + \sum_{n=1}^{\infty} \left[\nabla^2 g_m(x,y,z)\cos mu + \nabla^2 h_m(x,y,z)\sin mu\right] \equiv 0,$$

for all values of u, it is evident that  $g_m(x, y, z)$  and  $h_m(x, y, z)$  must be harmonics. As an illustration,

$$(z+ix\cos u+iy\sin u)^2 = z^2-\frac{1}{2}x^2-\frac{1}{2}y^2+2ixz\cos u$$

$$+2iyz\sin u + \frac{1}{2}(y^2 - x^2)\cos 2u - xy\sin 2u.$$

To obtain  $g_m(x, y, z)$  and  $h_m(x, y, z)$  explicitly, use Fourier's rule for determining the coefficients in a trigonometrical series, i.e., multiply the expansion of  $(z+ix\cos u+iy\sin u)^n$  by  $\cos mu$ and by  $\sin mu$ , and integrate with respect to u from  $-\pi$  to  $\pi$ It follows that

It will be proved later that these functions  $g_m(x,y,z)$  and  $h_m(x,y,z)$  are linearly independent, and so they form a set of 2n+1 independent harmonics.

The General Solution of Laplace's Equation .- It has just been seen that any harmonic of degree n may be expressed in the form

$$\sum_{m=0}^{n} a_{m}g_{m}(x,y,z) + \sum_{m=1}^{n} b_{m}h_{m}(x,y,z),$$

where  $a_m$  and  $b_m$  are constants. If now, for brevity,

$$\sum_{n=0}^{\infty} a_m \cos mu + \sum_{n=0}^{\infty} b_m \sin mu$$

be called  $\pi f_n(u)$ , it follows that any harmonic of degree n is expressible in the form

$$\int_{-\pi}^{\pi} (z+ix\cos u+iy\sin u)^n f_n(u)du,$$

where  $f_n(u)$  is a function of u; and, conversely, if  $f_n(u)$  is an arbitrary function of u, it may be verified by substituting the expression in Laplace's equation that it is a harmonic of degree n.

Next take any solution V of Laplace's equation and suppose it to be expansible in a convergent series of positive integral powers of x, y, z; group together all the terms of the same degree and replace each group of terms of the same degree n by an expression of the form

$$\int_{-\pi}^{\pi} (z+ix\cos u+iy\sin u)^n f_n(u)du;$$

it follows that

$$V = \sum_{n=0}^{\infty} \int_{-\pi}^{\pi} (z + iv \cos u + iy \sin u)^n f_n(u) du;$$

and this value of V is expressible in the form

$$V = \int_{-\pi}^{\pi} f(z + iv \cos u + iy \sin u, u) du,$$

where f denotes a function of the two arguments  $z+ix\cos u+iv\sin u$ and u; and conversely if f denotes an arbitrary function of its two arguments, the expression on the right may be shown to satisfy Laplace's equation

It is possible to remove the restriction concerning the possibility of expanding V as a series of positive integral powers of x, y, z; and hence the general solution of Laplace's equation may be

$$V = \int_{-\pi}^{\pi} f(z + ix \cos u + iy \sin u, u) du.$$

This solution was obtained by E. T. Whittaker in 1902; it may be compared with the solution of the equation

$$\frac{\partial^2 W}{\partial x^2} + \frac{\partial^2 W}{\partial y^2} = 0,$$

(known as Laplace's two-dimensional equation) namely

$$W = f(x+iy) + g(x-iy)$$

where f and g denote arbitrary functions.

Zonal, Tesseral and Sectorial Harmonics.-The 2n+1 harmonics of degree n which have been constructed take more simple forms when referred to polar co-ordinates; it is, in fact, possible to establish the expansion:

$$(z+ix\cos u+iy\sin u)^n=r^nP_n(\cos\theta)\ +\ 2\sum_{m=1}^n\frac{n!\ i^m}{(n+m)!}r^nP_n^m(\cos\theta)$$

 $(\cos m\phi \cos mu + \sin m\phi \sin mu)$  where  $P_n(\cos\theta)$  depends on  $\theta$ .

but not on 
$$\phi$$
, and  $P_n^m(\cos\theta) = \sin^m\theta \frac{d^m P_n(\cos\theta)}{d(\cos\theta)^m}$ .

From the form of the above expansion, it is evident that  $r^n P_n(\cos\theta)$  is identical with  $\frac{1}{2}g_0(x,y,z)$  so that

$$P_{\pi}(\cos\theta) = \frac{1}{2\pi} \int_{-\pi}^{\pi} \left\{ \cos\theta + i\sin\theta\cos(\phi - u) \right\}^{n} du,$$

it follows from the statement that  $P_n(\cos\theta)$  is independent of  $\phi$  that it is permissible to put  $\phi = 0$  in the last formula without affecting the result; and so

$$P_n(\cos\theta) = \frac{1}{2\pi} \int_{-\pi}^{\pi} (\cos\theta + i\sin\theta\cos u)^n du,$$

a formula known as Laplace's integral.

From the result stated, it follows that 2n+1 harmonics of degree n are

$$r^n P_n(\cos\theta), r^n P_n^m(\cos\theta)\cos m\phi, r^n P_n^m(\cos\theta)\sin m\phi,$$
  
 $(m=1,2,\cdots,n),$ 

and, from the manner in which  $\phi$  occurs in them, they are obviously linearly independent.

An alternative definition of  $P_n(\cos\theta)$  is derived from the fact that the potential produced at (x, y, z) by a unit mass at (0, 0, a) is  $1/\sqrt{x^2+y^2+(a-z)^2}=1/\sqrt{(a^2-2ar\mu+r^2)},$ 

in polar co-ordinates, where 
$$\mu$$
 denotes  $\cos\theta$ ; when this potential

function is expanded in ascending powers of r, the result is of the form

$$\frac{\mathbf{r}}{a} + \frac{rP_1(\mu)}{a^2} + \cdots + \frac{r^nP_n(\mu)}{a^{n+1}} + \cdots,$$

where  $P_n(\mu)$  depends on  $\mu$  and n only; and it may be seen from the expression in Cartesian co-ordinates that  $r^n P_n(\mu)$  is a harmonic of degree n; it is possible to identify  $P_n(\mu)$ , defined in this manner, with Laplace's integral; and it can be proved that

$$\begin{split} P_1(\mu) &= \mu, \quad P_2(\mu) = \frac{3 \, \mu^2 - 1}{2} \,, \quad P_3(\mu) = \frac{5 \, \mu^3 - 3 \mu}{2} \,, \cdots \,, \\ P_n(\mu) &= \frac{(2n)^4}{2^n \cdot (n!)^2} \left[ \mu^n - \frac{n(n-1)}{2 \cdot (2n-1)} \, \mu^{n-2} \right. \\ &+ \frac{n(n-1)(n-2)(n-3)}{2 \cdot 4(2n-1)(2n-3)} \, \mu^{n-4} - \cdots \right] . \end{split}$$

If a sphere is drawn with centre at the origin, the locus of points on the sphere at which  $P_n(\cos\theta)$  vanishes consists of the n parallels of latitude on which the cosine of the co-latitude is a root of the equation  $P_n(\mu) = 0$ ; the locus thus divides the sphere into n+1 zones, and for this reason  $r^n P_n(\cos \theta)$  is called a zonal harmonic

In like manner when  $n > m \ge 1$ ,  $P_n^m(\cos \theta)$  vanishes on n-mparallels of latitude, while cos mo vanishes on 2m meridians, and sin mφ vanishes on 2m other meridians; the sphere is thus divided into 2m(n-m-1) rectangular regions, with 2m triangular regions round each pole, and for this reason  $r^m P_n^m(\cos \theta) \cos m\phi$ and  $r^n P_n^m(\cos\theta) \sin m\phi$  are called tesseral harmonics  $(\tau \epsilon \sigma \sigma \epsilon \rho \alpha = a)$ 

For similar reasons  $r^n P_n^n(\cos\theta) \cos n\phi$  and  $r^n P_n^n(\cos\theta) \sin n\phi$ are called sectorial harmonics.

The function  $P_n(\cos\theta)$  is called a Legendre coefficient, or a Legendre function, while  $P_n^m(\cos\theta)$  is called an associated Legendre function.

Normal Solutions of Laplace's Equation.—The zonal, tesseral and sectorial harmonics are of the form  $R \Theta \cdot \Phi$  where  $R, \Theta, \Phi$ respectively involve the co-ordinates,  $r, \theta$ ,  $\phi$ , only; a solution consisting of the product of three functions each involving only one co-ordinate is called a normal solution.

Thus, if  $X \cdot Y \cdot Z$  is a normal solution of Laplace's equation in Cartesian co-ordinates, it follows, on substitution and division by XYZ, that

$$\frac{\mathbf{I}}{X} \frac{\partial^2 X}{\partial x^2} + \frac{\mathbf{I}}{Y} \frac{\partial^2 Y}{\partial y^2} + \frac{\mathbf{I}}{Z} \frac{\partial^2 Z}{\partial z^2} = 0,$$

$$\mathbf{I} \frac{\partial^2 X}{\partial x^2} = \mathbf{I} \frac{\partial^2 Y}{\partial x^2} + \mathbf{I} \frac{\partial^2 Z}{\partial z^2} = 0,$$

 $\frac{1}{V} \frac{\partial^2 X}{\partial x^2}, \quad \frac{1}{V} \frac{\partial^2 Y}{\partial x^2}, \quad \frac{1}{Z} \frac{\partial^2 Z}{\partial x^2}$ and so

must be respectively independent of x, y, z; hence they are constants. If these constants are called  $a^2$ ,  $b^2$ ,  $c^2$ , where  $a^2+b^2+c^2=0$ , we obtain the solutions

$$V = e^{\pm ax \pm by \pm cz}$$

Similarly, if ROP is a normal solution in polar co-ordinates,

$$\frac{1}{R} \ \frac{d}{dr} \left( r^2 \frac{dR}{dr} \right) + \frac{1}{\Theta \sin \theta} \ \frac{d}{d\theta} \left( \sin \theta \frac{d\Theta}{d\theta} \right) + \frac{1}{\Phi \sin^2 \theta} \ \frac{d^2 \Phi}{d \phi^2} = o,$$

and so 
$$\frac{1}{R} \frac{d}{dr} \left( r^2 \frac{dR}{dr} \right)$$
 and  $\frac{1}{\Phi} \frac{d^2 \Phi}{d\phi^2}$  must be constants, say

n(n+1) and  $-m^2$ ; and so  $\Theta$  satisfies the equation

$$\frac{1}{\sin\theta} \frac{d}{d\theta} \left( \sin\theta \frac{d\Theta}{d\theta} \right) + \left( n[n+1] - \frac{m^2}{\sin^2\theta} \right) \Theta = 0,$$

while 
$$\frac{d}{dr}\left(r^2\frac{dR}{dr}\right) - n(n+1)R = 0$$
,  $\frac{d^2\Phi}{d\phi^2} + m^2\Phi = 0$ .

Possible values of R are  $r^n$  and  $r^{-n-1}$ ; and possible values of  $\Phi$ are cos mo and sin mo. But now n and m are not necessarily integers, and so the question arises of defining  $P_n^m(\cos\theta)$  in such circumstances

This problem is dealt with by means of the hypergeometric function of Gauss defined by the equation

$$F(\alpha, \beta; \gamma; z) = 1 + \frac{\alpha\beta}{\gamma \cdot 1} z + \frac{\alpha(\alpha+1)\beta(\beta+1)}{\gamma(\gamma+1) \cdot 1} z^2 + \cdots,$$

A solution of the equation which it is convenient to adopt as the definition of  $P_n^{m}(\cos \theta)$  is

$$P_n^m(\cos\theta) = \frac{\mathrm{I}}{\Gamma(\mathrm{I}-m)} \left(\frac{\mu+\mathrm{I}}{\mu-\mathrm{I}}\right)^{\frac{1}{2m}} F(-n,\,n+\mathrm{I}\,;\,\mathrm{I}-m\,;\,\frac{1}{2}-\frac{1}{2}\mu),$$

where  $\Gamma(\mathbf{r}-m)$  denotes the gamma function of Euler which reduces to (-m)! when m is a negative integer (when m is a positive integer, this function differs from the associated Legendre function, as previously defined, by a constant factor). The theory of generalized Legendre functions is consequently merged into the wider theory of hypergeometric functions.

Cylindrical and Ellipsoidal Harmonics.—The cylindrical co-ordinates  $(\rho, \phi, z)$  of a point are defined by the equations

$$x = \rho \cos \phi$$
,  $y = \rho \sin \phi$ ,  $z = z$ .

When the solution  $e^{i(x+ix\cos u+iy\sin u)}$  of Laplace's equation is expressed in terms of such co-ordinates it becomes:

and this can be expanded in the form

$$e^{kz} \left[ J_0(k\rho) + 2 \sum_{m=1}^{\infty} i^m J_m(k\rho) \left( \cos m\phi \cos mu + \sin m\phi \sin mu \right) \right]$$

where

$$J_m(k\rho) = \sum_{n=0}^{\infty} \frac{(-1)^n (\frac{1}{2}k\rho)^{m+2n}}{n!(m+n)!}$$

This leads to the consideration of the cylindrical harmonics  $e^{kz}J_0(k\rho)$ ,  $e^{kz}J_m(k\rho)\cos m\phi$ ,  $e^{kz}J_m(k\rho)\sin m\phi$ ,

which may also be derived as normal solutions of Laplace's equation in cylindrical co-ordinates, viz.

$$\frac{\mathbf{I}}{\rho} \ \frac{\partial}{\partial \rho} \left( \rho \frac{\partial V}{\partial \rho} \right) + \frac{\mathbf{I}}{\rho^2} \ \frac{\partial^2 V}{\partial \phi^2} + \frac{\partial^2 V}{\partial z^2} = \mathrm{o}.$$

The functions  $J_m(kp)$  are known as Bessel functions (q.v.). They occur in numerous physical problems of diverse types including F. W. Bessel's investigations of planetary motion, Daniel Bernoulli's problem of a vibrating hanging chain and L. Euler's problem of a vibrating circular membrane.

The functions which occur in a similar manner when Laplace's equation is referred to a system of confocal conicoids as surfaces of reference are known as Lamb's functions; these are of a more complicated type than the functions described hitherto, because they cannot be expressed as series with simple coefficients. But when the confocal conicoids are spheroids, the substitution

$$x=(r^2-c^2)^{\frac{1}{2}}\sin\theta\cos\phi, \quad y=(r^2-c^2)^{\frac{1}{2}}\sin\theta\sin\phi, \quad z=r\cos\theta$$
 gives a form of Laplace's equation with normal solutions of the type

$$P_n^m(r/c)P_n^m(\cos\theta) \sin^{\cos\theta} m\phi$$

the spheroids being prolate; with oblate spheroids,  $\epsilon$  must be replaced by  $i\epsilon$ .

Recent Researches.—Some of the main lines along which progress has been made in recent years include methods of transforming the hypergeometric series; obtaining approximate expressions for  $P_n^m(\cos\theta)$  when n or m (or both) is large; expanding arbitrary functions of two variables as series of surface harmonics expanding arbitrary functions  $f(\mu)$  in the form  $\sum a_p P_n(\mu)$ ; obtaining approximate formulae for  $J_n(z)$  when z or n (or both) is large; obtaining formulae by which the roots of the equation  $J_n(z) = 0$  may be calculated; expanding arbitrary functions as series of Bessel functions; obtaining integral equations satisfied by ellipsoidal harmonics, and by the harmonic functions associated with confocal elliptic cylinders. These investigations all arose in the first instance out of some problem of Mathematical Physics, though many of them require the most profound methods of Pure Mathematics for their solution.

**SPHEROID**, literally a sphere-like body. In geometry the term is applied to figures generated by an ellipse (q.v.) revolving about either its minor axis (giving an oblate spheroid) or its major axis (giving a prolate spheroid). If the equation of the generating ellipse is  $b^2x^2+a^2y^2=a^2t^3$ , and the ellipse revolves about the major axis (the x axis), the volume is  $\frac{4}{\pi}ab^2$ ; if about the minor axis, it is  $\frac{4}{\pi}a^2b$ . The equation of the prolate spheroid is  $b^2x^2+a^2(y^2+z^2)=a^2b^2$ , and of the oblate spheroid it is  $b^2(x^2+z^2)+a^2y^2=a^2b^2$ . (See ELLIPSOID.)

SPHERULITES, in petrology, small rounded bodies which commonly occur in vitreous igneous rocks. They are often visible in specimens of obsidian, pitchstone and rhyolite as globules about the size of millet seed, with a duller lustre than the surrounding glassy base of the rock, and when they are examined with a lens they prove to have a radiate fibrous structure. Under the microscope the spherulites are of circular outline and composed of thin divergent fibres, which are crystalline and react on polarized light. Between crossed nicols a black cross appears in the spherulite; its axes are usually perpendicular to one another and parallel to the crossed wires; as the stage is rotated the cross remains steady; between the black arms there are four bright sectors. This shows that the spherulite consists of radiate doubly refracting fibres which have a straight extinction; the arms of the black cross correspond to those fibres which are extinguished. The aggregate is too fine grained for us to determine its minerals.
